Textbook type of information is not what is generally desired but rather concise information relative to the therapeutic possibility of the drug, its tolerance, toxicity and its incompatibilities and contraindication if such exist. Dosage, of course, is essential but this is now supplied in both the National Formulary and the United States Pharmacopeia. If the item is an official vehicle, then that vehicle should be described as to its flexibility and ramifications of usefulness.

For example, it would be well to inform the physician about the amount of water which Hydrophilic Petrolatum will absorb; the possibility of adding water to Hydrophilic Ointment to make it available in lotion form; the many features of Polyethylene Glycol Ointment including its ready removal from the skin, its nonoleaginous nature; and the question of concentrations of medicament when used in these vehicles.

New Directions for Research in Infant Care

Further research to establish the general relationships between infant mortality and such factors as income level and occupation is probably needless, according to Dr. Odin W. Anderson, research director of the Health Information Foundation, New York City (*The Child*, April 1953 issue). A direct and undiminished correlation between a high standard of living and low infant mortality is assumed. Where infant mortality rates go higher than 30 per 1,000 live births, an improvement in the standard of living will have a long-range effect, as it has since 1890 in various countries. But when the infant mortality rate drops to about 30, the broad economic and social factors operate with lessening effect. Then an increasing influence on the rate begins to be exercised by personal factors in the care of the baby, like adequacy of mothering and readiness—and ability—to use proved methods of infant care. Given the essentials of living, use of a bottle sterilizer can have a greater effect in some families on saving babies' lives than a \$500 annual increase in income.

Infant mortality is often referred to as a sensitive index level. Where the health level is low, whether in wartime or peacetime, the infant mortality is high accordingly. Rates vary widely between countries, between areas within coun-

tries, and even between residential areas within cities. Obviously, factors other than general economic ones account for the low infant mortality rates among the foreign-born Jewish group studied in an early analysis (1911 to 1916) of infant mortality in eight cities in the United States. The Jewish group experienced the lowest infant mortality rate of all groups studied—54—and the lowest neonatal mortality rate—28. Closer examination would probably reveal a pattern of infant care of a high order embedded in the Jewish culture.

Dr. Anderson believes that other than purely medical research, further exploration could well be made of the illness of babies in relation to socioeconomic factors. Another subject for investigation, he suggests, is the effect of adverse socioeconomic conditions on the unborn baby and on the ability of the mother to bear a full-term healthy baby. Two of the many questions still unanswered concerning the relationship of socioeconomic and ethnic factors to infant deaths are, he writes: What are the environmental conditions in localities where infant mortality is still extra high by modern standards? How do traditional ways of caring for infants in various ethnic groups affect the survival of infants in these groups?

—*The Child* is issued by the Children's Bureau, U. S. Department of Health, Education, and Welfare. \$1.25 a year (\$1.50 foreign mailing), 15¢ a copy, from the Superintendent of Documents, Government Printing Office, Washington 25, D. C.

Survey of Consultant Nurses In Health Agencies

By PEARL McIVER, R.N., M.A.

AT THE REQUEST of the Council of State Nursing Directors at their meeting in California in October 1951, a limited, exploratory survey of consultant nurses employed by State and local health agencies was begun by the Public Health Service. The survey was proposed to aid State health departments in planning for nurses' participation in the many new health programs, such as chronic disease, occupational health, and mental health, and as a guide to universities which offer courses in the specialties designed to prepare consultant nurses.

Source of Data

The data were obtained from 48 State and Territorial health departments and consisted of an individual personnel history and a job description on each consultant nurse on duty January 1, 1952, in a State or local health agency. Records were received on almost 500 nurses but not all were used. Some were for personnel whose primary responsibilities were administrative rather than consultative and were therefore not included in this survey. Of the 458 consultants for whom records were received, 315 were employed by State health departments, 65 by other State agencies, and 78 by local health agencies.

The personnel histories were accurate and fairly complete for general academic education

and university preparation in public health nursing, but they were sometimes incomplete with regard to nursing experience and preparation in the specialties. Some of the job descriptions were clear and comprehensive, but many were either too general or contained too much detail. Therefore, no attempt was made to give definite numerical ratings to functions or responsibilities of the nurses.

A progress report was given to the State nursing directors who attended the American Public Health Association meeting in Cleveland in October 1952. At that meeting, the State nursing directors agreed to send to the Public Health Service author supplementary data on the amount and kind of training in a specialty for consultant nurses who were serving State agencies. By January 14, supplementary data had been received from 42 States and were added to the previous material.

After the preliminary tabulations were completed the data were given to groups of special nursing consultants in the Public Health Service and in the Children's Bureau for review and comment. The data contained so much information of interest to the Federal consultants that each group agreed to prepare a detailed report on their respective specialties. This report, however, summarizes only the general information obtained from the survey.

Responsibilities of Nursing Consultants

Primarily, a consultant nurse is an adviser to and a teacher of other nurses. Unlike a supervisor, she does not have administrative responsibility for the nurses she is helping. She

Miss McIver is chief of the Division of Public Health Nursing, Public Health Service. The material in this article was prepared by the division's staff.

gives consultation in her special field to official and voluntary health agency personnel. She also interprets the program in her specialty to the general public. Her success depends upon the needs for her special knowledge and skills, her ability to create a desire for her services where the needs exist, and her ability to fill these needs.

Consultation is a two-way channel. The consultant learns from the nurses, health officials, and general citizens what the needs are and how well the proposed plans meet those needs. The consultee benefits from the broader knowledge and experience which the consultant brings to a discussion of a common problem.

From the job descriptions submitted, the functions and responsibilities of consultants were grouped into 8 categories, of which 5 could be classified as common functions in any consultation program. These five were: education, studies and surveys to determine needs and resources, policy formation and program planning, interpretation of policies and plans, and evaluation of special programs. Most of the consultants also had some responsibilities in one or more of the other three: administration, supervision, and provision of direct services. Some were participating in the administration of a special program, some were giving direct supervision to local nurses where no local supervision was provided, and a few were providing direct services in a specialty to areas of a State where there were no organized health services.

Types of Consultants

Of the 315 consultant nurses in State health departments, 291 devoted full time to one field, and 24 served in more than one specialty or added consultation in a specialty to their general responsibilities. Only in the chronic diseases was one consultant responsible for more than two programs, and since the total number of consultants in this category (heart, cancer, geriatrics, diabetes) was small, the consultants in these fields have been grouped under the chronic disease category.

The 98 general public health nursing consultants outnumbered all other categories in State agencies. Only 18 of the 98 carried a specialty in addition to their general responsibilities. Four combined tuberculosis and gen-

eral consultation. Two were also venereal disease consultants; one was also director of field training. One gave consultation in industrial hygiene, and two in chronic disease, in addition to serving as general public health nursing consultants. Seven combined maternal and child health services and one combined crippled children's services, with general consultation.

Nursing consultants for crippled children services were the next largest group. Of 93 such consultants, 31 were employed full time by State health departments except for 1 who served part time as a general consultant. Fifty-four were full-time employees of other State agencies for crippled children. Eight were employed by local agencies.

Of the 69 consultants in maternal and child health nursing, the third largest group of consultants, 53 were employed in State health departments. Forty-five in State health departments devoted full time to this field and 8 part time. The 8 carried additional responsibilities, 7 for general consultation and 1 for educational work.¹ Sixteen were in local agencies.

Tuberculosis nursing consultants were the next largest group. Of the 44 in this specialty, 34 were employed by State health departments; 28 full time. Four served part time in the general field, 1 spent part time on venereal disease consultation, and another spent part time on the chronic disease program. Five were employed by other State agencies and 5 by local health agencies.

Hospital nursing consultants are among the newest type. A total of 40 were reported; 23 general hospital or nursing consultants on full-time duty in State health departments. There were 12 maternal and child health hospital nursing consultants in State health departments. Five hospital nursing consultants were employed full time in local health agencies.

Educational consultants were employed by 37 agencies. In State health departments, 17 served full time and 4 part time. The 4 divided their time, 1 each with general, venereal disease, industrial, and maternal and child health consultation. Educational consultants (or educational directors) made up one of the largest groups (16) in the local agencies.

Figure 1. Distribution of full-time and part-time nursing consultants in State and local health agencies by type of program on January 1, 1952. (Twenty-four consultants served part time in 48 programs.)

Of the 24 industrial nursing consultants employed by State health departments, 22 were full time. One spent part time as educational director and another carried a district for general consultation. Only one industrial consultant nurse was reported from other State agencies although previous reports indicate that there are additional industrial nursing consultants in State labor departments. Five were employed by local health agencies.

Mental health consultants ranked next with 22. Only eight worked full time in State health departments. Four were employed full time by other State agencies and 10 by local agencies.

Venereal disease nursing consultants were employed by 20 State and local agencies. Of the 15 in State health departments, 10 served full time. Two were also responsible for general consultation. One served part time in tuberculosis; one gave part of her time to

chronic disease, and one served as part-time educational consultant on field training activities. Local health agencies employed five full-time venereal disease consultants.

Chronic disease consultants compose a group of 14 nurses: 11 in State health departments, 1 in another State agency, and 2 in local agencies. Two were serving as full-time cancer nursing consultants in a State health department. In two States, cancer consultation was combined with cardiac control consultation, and in one State, cancer and general consultation were combined. In one local visiting nurse association, one nurse served in cancer control.

Two States reported full-time chronic disease nursing consultants. In one State chronic disease and general consultation were combined, and another State combined chronic disease with venereal disease control consultation. One State health department and one other

State agency supplied full-time nursing consultants on rheumatic fever, and in one State health department, tuberculosis and cardiac consultation were combined. One local health department had a full-time consultant on rehabilitation.

Communicable disease nursing consultants were a slightly smaller group. Five were serving in State health departments, and five in city health departments. All were full time.

Other nursing consultants were reported from 4 States and 1 city: 1 full-time consultant for civil defense, 1 for dental health, 1 on community organization, and 1 for vision and sight conservation. One nurse in a city health department served as a full-time consultant on records and statistics.

Figure 1 shows the distribution of nursing consultants in State and local health agencies, by type of program.

Functions of Consultants

Examination of position descriptions in terms of the eight categories of responsibilities previously cited not only indicates the scope of consultation but also reveals limitations and suggests points for further consideration.

Most of the functions of the consultants are educational. The groups to whom the educational programs were directed, in order of frequency, were State and local health personnel; nursing students, basic and graduate; hospital and other institutional workers; industrial nurses and their employers. In carrying out their responsibilities in this category, consultant nurses conducted institutes and work conferences, prepared manuals and guides, selected and distributed educational material on their specialties, demonstrated specific techniques and procedures, and oriented new personnel.

Practically every job description mentioned responsibility for studies and reports. A large number mentioned helping to plan and organize case-finding surveys for tuberculosis, diabetes, and venereal disease. A few mentioned studies of educational resources and surveys of treatment facilities in their specialties.

Only a few job descriptions mentioned participating in policy formation and in planning

the overall program in their specialties. If the consultant nurse is to make her maximum contribution to a disease control or health promotion program, she must be a member of the team having overall responsibility for that program.

If the consultant's office is in a different building, or even in a different section of the same building, will she have the opportunity to participate in informal conferences where many of the preliminary, as well as final plans are made? The job descriptions did not record policy formation and planning frequently. Does that mean that the directors of special programs minimized her contribution or that the nursing consultant believed such participation was unimportant?

Many functions pertaining to interpreting policies and plans to local health agencies, other State agencies, and professional organizations were recorded. Since this was a frequent function of the consultant nurse, she should have a real contribution to make in the formulation and revision of policies and plans.

Only a few of the job descriptions recorded specific functions on evaluating the effectiveness of special programs and efficiency of nursing personnel functioning within the program. All of the special program divisions depend to a large extent upon the local general nursing staff to translate their programs into action in local areas. Is not one of the important purposes of a consultation program to help local health officers and nurses to measure the effectiveness of their special programs?

In most instances, consultants employed by State health departments recorded "direct service in local areas" less frequently than did the consultants employed by other State agencies. These data did not reveal why this was so, but it is logical to suggest that the State health department personnel are more familiar with local health department facilities and therefore refer special problems to the local personnel, while some other State agencies may not have as direct contact with local health agencies.

Administrative functions in connection with the special programs were recorded most frequently in those States where there was no full-time administrator of that special program or a very limited administrative staff. In one State a nurse is assistant administrator of the

Figure 2. Percentage distribution of nursing consultants employed by State and local health agencies on January 1, 1952, by academic education.

maternal and child health program. No doubt she gives some nursing consultation, but since administration was her primary responsibility, she was not included in this study. However, in another small State, the nursing consultant was the administrator of the mental hygiene program, and in one State the tuberculosis nursing consultant had the major responsibility for directing the tuberculosis control program.

Professional Preparation
Academic Education

Of the 458 consultants employed in State and local health agencies, 353, or 77.0 percent, had 1 or more college degrees. One hundred seven, or 23.3 percent, had master's degrees and 246, or 53.7 percent, had bachelor's degrees only. Eighty-nine, or 19.4 percent, had some college work and 16, or 3.4 percent, had no college work or no information was submitted on this item. The group of consultants employed in local health agencies showed the highest percentage (87.2) with degrees. State health department consultants ranked second with a percentage of 77.1 percent and the lowest percentage (64.6) was shown by the group serving in other State agencies (fig. 2).

Public Health Nursing

A program of study in public health nursing is an accepted requirement for nursing consultants in the field of public health. Four hundred and eighteen (exclusive of 40 hospital

nursing consultants) served in public health programs. Of these, 360, 86.1 percent, had completed a program of study in public health nursing; 20, 4.8 percent, had had some public health nursing study; and 38, 9.1 percent, had had none or submitted no information on this item. The consultants in local health agencies ranked highest among those who had completed a program of study in public health nursing, with a percentage of 90.4. The State health department consultants showed a percentage of 88.9 and those in other State agencies a percentage of 69.2 (fig. 3 and table).

Not every record gave information on the length of present employment. From the records, it appeared that those consultants without university preparation in public health nursing had been in their positions for a number of years.

Although a program of study in public health nursing is not considered a requirement for hospital nursing consultants, it was found that 17 of the 40 hospital consultants were so qualified. About one-third of the hospital nursing consultants reported some university preparation in their specialty.

Postgraduate Education in the Specialty

Postgraduate education in the specialty is generally thought of as one of the requirements for a consultant serving in a specialty. There has been a rapid expansion of specialties in public health programs within recent years and a

Figure 3. Percentage distribution of nursing consultants, exclusive of hospital nursing consultants, on January 1, 1952, by public health nursing education.

concomitant growth in the number of specialized nursing consultants employed. There is no clearly defined program of study for some of the categories of consultants represented in this report. The questions of what constitutes educational preparation in a specialty and what categories should be considered as specialties appear to need further exploration and study.

A sampling of data submitted on 139 consultants in State health departments (exclusive of the 80 general consultants and 96 consultants engaged in maternal and child health and programs for crippled children) revealed that 105 or slightly more than three-fourths of them had had some postgraduate education in their specialty, varying from institutes of 1 week's duration to 18 months of formal study. In view of the limitations of the data no attempt is made to show this type of education

in over-all table form. The detailed report of each specialty will include a discussion of postgraduate education in the respective fields.

Experience

When information concerning previous experience was not recorded, it was coded on the punch card as "none." Quite frequently the reviewers were reasonably certain that the answer was "no experience reported" rather than "none." However, it was not possible to separate those who failed to record experience from those who had no previous experience. Therefore, this report gives only a general picture of the background experience of the consultants.

The specialties in which the largest majority of the consultants recorded previous experience in general public health nursing supervision were venereal disease, tuberculosis, and mater-

Public health nursing education of nursing consultants employed in State and local health agencies exclusive of hospital nursing consultants, as of January 1, 1952

Type of agency	Total consultants		Amount of public health nursing education					
			Completed program of study		Some public health nursing study		None or no information	
	Number	Percent	Number	Percent	Number	Percent	Number	Percent
All agencies.....	418	100	360	86.1	20	4.8	38	9.1
State health departments.....	280	100	249	88.9	12	4.3	19	6.8
Other State agencies.....	65	100	45	69.2	6	9.2	14	21.6
Local agencies.....	73	100	66	90.4	2	2.7	5	6.9

nal and child health. Consultants in mental health, crippled children, and education ranked next highest insofar as previous public health nursing experience was concerned. About one-third of the general and industrial nursing consultants either had no previous public health experience or failed to record their past experiences.

Experience in public health nursing is a specified requirement in announcements of qualifications for appointment to any consultant position in the field of public health nursing. Many of the examination announcements specify experience in general public health nursing, and in addition, require experience as a public health nursing supervisor prior to appointment to a consultant position. Some of the States have required public health nursing experience of those nurses who were appointed as hospital nursing consultants. Desirable as it may be to have every nurse prepared for first level work in public health nursing, it would appear that, for hospital nursing consultants, experience as a hospital nursing supervisor or administrator is more important than experience as a public health nursing supervisor if only one type of experience is required.

About one-third of the hospital nursing consultants recorded public health nursing experience prior to their present assignments. All of those who had not had public health nursing experience reported experience in clinical supervision, teaching, or administration of nursing services. Two of the hospital nursing consultants with previous public health nursing experience had had no experience in clinical nursing.

Clinical experience in the specialty was reported most frequently by the public health nursing consultant in maternity and child health. About 30 percent of the industrial nursing consultants reported experience within industry which might be likened to clinical experience in the other specialties. Less than 10 percent of the consultants in the other specialties reported previous clinical experience in their specialty.

Discussion

Many of the job descriptions did not define clearly the responsibilities of the position. The

nursing service would be strengthened if these descriptions were more comprehensive. An accurate description of the duties and responsibilities of a position, kept up to date at least biennially in accordance with changes in program emphases, would help and guide a new appointee to the position.

A number of the personnel histories submitted for this study apparently were prepared years ago and from those records it would appear that the present incumbent did not meet the professional requirements specified by the State merit system agency for that particular position. For one-third of the general public health nursing consultants, no public health experience prior to that obtained in the present position was recorded. Personal acquaintance with many of these nurses convinces the reviewers that no information was given rather than the inference that so many of the general consultants had had no previous public health nursing experience.

The nursing consultants included in this study were well prepared academically for their responsibilities. Formal preparation for some of the specialties has not yet been well defined, but at least one university has experimented with, and this year is offering, a program in chronic disease and tuberculosis. What should the content include and how much time is required to prepare nursing consultants for such specialties?

A considerable number of the job descriptions specifically mentioned the consultants' responsibility in assisting basic schools of nursing with the integration of that specialty in the undergraduate curriculum. This is an encouraging development and indicates the health agencies' interest in and responsibility for participation in basic nursing education programs.

General hospital nursing consultation services in State health departments, for the most part, have been developed since the passage of the Hospital Survey and Construction Act. This consulting service was provided in 15 States on January 1, 1952.

In addition to the general hospital nursing services, it was encouraging to note the frequency with which the job descriptions of consultants in such specialties as tuberculosis, ma-

ternal and child health, cancer, and venereal disease listed as one of their functions "giving consultation to hospital and sanatorium personnel." Good patient care requires a close liaison among those persons responsible for care during the preventive and case-finding stages, the treatment period, and the recovery and rehabilitative stages.

A lack of experience or training in modern hospital procedures may have limited the number of consultants who gave service to hospitals and medical care institutions. Is clinical nursing an area that should be emphasized in in-service education programs for public health nursing consultants?

Comparatively few of the nursing consultants were designated as consultants for more than one specialty. Only 24 out of 458 were listed as specifically serving in more than one specialty. Of the 24, only 18 were general consultants with designated responsibility for a specialty also. Undoubtedly all of the 80 full-time general public health nursing consultants devoted considerable time to each of the specialties.

The newer programs, such as heart, cancer, and geriatrics, which we have tabulated as the chronic disease category, reported only 11 consultants with specific responsibility for one or a combination of specialties in State health departments. The trend in State health department organization appears to point to a combination of several disease control programs, grouped under a unit designated as the bureau of preventable diseases; or into one unit concerned with chronic or long-term illnesses; or another bureau concerned with epidemic or acute illnesses which have public health significance. It was hoped that this study would reveal a similar grouping of public health nursing combination services. The data do not reveal any significant number of combinations. Neither do these data reveal to what extent

the general consultants participated in the special programs.

Questions for Consideration

These data show that there has not been much experimentation with the idea of having one well-qualified nursing consultant to serve two or more related specialties. If all of the long-term health problems, such as heart, cancer, diabetes, geriatrics, and rehabilitation, were grouped under one bureau, could one nursing consultant serve them all if she were not required to render direct service locally in addition to her consultant functions? Could a combination of the acute communicable diseases, including venereal disease, be handled similarly by one nursing consultant skilled in epidemiological techniques and procedures? Would the educational consultants be more valuable teachers and leaders if they were skilled mental health consultant nurses since mental health should be an integral part of every health program?

Special consultation services should not be developed at the expense of adequate local nursing supervision or at the expense of the provision of high quality general public health nursing consultation which is essential to insure the coordination of all programs. There is a shortage of qualified public health nursing administrators, supervisors, and consultants. How can the services of each be used most effectively?

A study made of personnel history records and job descriptions could furnish a wealth of information provided all of these records were accurate and complete. Even with the limitations of the 1952 data in this survey, the Federal nursing consultants found the data very useful. If an effort is made by each agency to improve these two sources of information, and a number of States try some new combinations during the next few years, would it be valuable to repeat a study of this type every 5 years?

Science and Public Health Research in Alaska

Alaska, one of today's "new frontiers," is witnessing an important growth in scientific undertakings. Not the least of these are investigations in public health and related fields of science. Reviewing development of the Public Health Service's Arctic Health Research Center at Anchorage, the late Dr. Joseph W. Mountin wrote:

"In the past, public health activities have developed in the wake of civilization. Now public health is presented with an opportunity to lead civilization, to pioneer in new fields. By uncovering some of the problems of human life and adjustment in low-temperature areas, public health can become a creative force in opening up new frontiers. At the same time it can make potentially significant contributions to basic knowledge."

Last September—4 years after the beginnings of the Arctic Health Research Center—the Third Alaskan Science Conference was held at Mt. McKinley National Park under the sponsorship of the American Association for the Advancement of Science's Alaska Division, which grew out of the first Alaskan Science Conference in Washington in 1950.

Conference topics in 1952 ranged from agriculture, forestry, and botany to zoology and wildlife, and from anthropology to sociology, economics, and education. *Public Health Reports* has selected 10 papers for reporting "in brief." These represent only a few of the many topics touching upon the difficulties of introducing modern technology and methods of living to an old civilization and primitive methods of living. With one exception, all the briefs deal with specific health topics.

The exception is a paper of Dr. Margaret Lantis on the role of science in general and social science in particular in a pioneer environment which lends itself as an ideal laboratory for scientific research. This discussion is presented in the form of two briefs.

The Trend of Science

PHR The scientist is a person who lives for and in the future. He is a dreamer with self-discipline. His objective is to state generalizations, principles, propositions, tendencies, and laws that are the bases for prediction.

The scientist must always stand the test of prediction, for prediction is an essential part of scientific method. Even though a paleontologist or archaeologist is concerned with reconstruction of the past and does not expect to see trilobites or Mousterian man on earth again, he uses history to formulate principles of anatomic or cultural change. In other fields, the use of prediction is even more immediate.

But philosophers state principles, and everyone predicts. Any person functioning as a scientist is different, however, in his use of exact methods, in his willingness to reveal these methods to others without distortion, and in his integrity and impersonality in stating his observations. Thus, he is, or should be, always conscious of standing the test of the future. He constantly seeks new ideas, new methods.

The scientist disciplines himself in formulating exact plans for research. He disciplines himself to be a meticulous observer and recorder, to make careful reports and cautious claims, and to accept criticism.

The scientist not only sees what will happen, he tries to understand why it will happen. As he learns more of the why, he becomes more accurate in predicting. He is either a watcher or a tinkerer—the natural historian or the experimenter. Both are necessary. Generally, the watchers have preceded the tinkerers. They had to see what was there before they started working on it. Just to go out and collect was important and sufficient 50 or 75 years ago.

Experimental Biology

In the past 50 years, the Biological Survey, the Reindeer Service, and others in Alaska have

By Margaret Lantis, Ph.D., anthropologist, Arctic-Desert-Tropic Information Center, Maxwell Air Force Base, Ala. This and the following brief are from one paper.

made field experiments, necessarily uncontrolled for the most part; hence, with more hope than prediction. Then, in 1948 the Arctic Health Research Center of the Public Health Service was established. Its work leads us to the real objective of science, from a humanistic standpoint: treatment and prevention. Along another line of development is biological engineering, one form of which is exemplified in the Fishery Products Laboratory, another new institution in Alaska. There is also the Agricultural Experiment Station. But laboratory experimentation in special fields of zoology and physiology is recent in Alaska.

In other new programs in Alaska, the scientists are, as usual, looking ahead, in application as well as in the formulation of theory. This is especially true when we are studying behavior. Are the southeast Alaskans successfully combating tuberculosis while the interior Indians are not? Ten or 50 years later, no doubt one can say what happened, but he may have difficulty answering the questions of why and how. It is important, therefore, to study events while they are happening, not after they happen.

The modern scientist is just the opposite of the popular stereotype who mounts moths on pins but is unaware that caterpillars are destroying the orchard. Even if he is not an economic entomologist, the modern scientist, because he is so interested in processes, in the dynamics of life, is a Johnny-on-the-spot, watching the processes as they occur.

The Social Sciences

Sociology has suffered from both internal and external difficulties. Internally, there was too much and too early emphasis on social pathology. The curriculum contained courses labeled "criminology," "social disorganization," and "problems of social welfare." Ecology seemed to become only a study of blighted areas of cities. Lectures on "the family" dealt chiefly with family disintegration and divorce. The sociologist and some of his fellow social scientists always seemed to show up the worst in the community. Just by trying to be disciplined scientists, they antagonized many laymen, especially civic boosters.

The psychologist has had the same difficulty whenever he went beyond a study of special

abilities. In the study of the dynamics of the personality, there was more "abnormal" than "normal" psychology. And the layman felt uncomfortable and suspicious. Instead of being reminded how remarkably subtle and clever, yet consistent and strong, is the individual personality, he was made to feel that he was full of irreconcilable conflicts and about to go off his rocker.

Fortunately, in sociology, social anthropology, and social psychology the early stage of discovering all the awful things that are wrong with man—his logic-tight compartments, sibling rivalry and Oedipus complex, racial prejudice, and culture lag—has been passed.

Now, in psychology we are hearing about ego strength and ego ideals; in anthropology, about the cultural values—the commonly shared concepts that people live by; and in sociology, about the processes of achieving consensus or agreement. These topics of study are not only positive, they are dynamic.

The Natural History Stage

It is hard to experiment in the field of human relations when it is still in the natural history stage. We who make field studies as well as theorize about people and politics are the natural historians of man, trudging up and down the hills of society. But we now have a much better understanding of scientific problem and the formulation of hypothesis. And we have more sense in the use of special tools for field study; for example, opinion polls. It does seem that in many fields there is a renaissance of good old field observation, a refined natural history done with remarkable new tools.

Some of the social scientists also are seeing the value of a well-rounded natural history, not because they went too rapidly and exclusively into experimentation but because they tried prematurely to formulate rigid laws. Economists, for example, have found that economic man is at the same time social man and political man. Another difficulty, or supposed obstacle in social science, is the complexity of human behavior. Actually, it is not as complex as, for example, the chemistry of the human body. The only difficulty is simply the lack of data: the number of scientific observers for such a very big subject is very small.

The Social Sciences

PHR Where does Alaska fit in the trend of science? What should the scientist study in Alaska? Clearly Alaska needs people working in basic social science, studying processes of the formation of a new society. For nowhere—certainly not in Alaska—is there now enough of basic science in the field of social relations. Yet few areas offer better opportunities to study the social dynamics of a city virtually from the beginning than does Anchorage with its population growing so fast that it's almost a demographic explosion. Social organizations are multiplying in Alaska like rabbits in Australia.

Alaska offers a manageable field for study. Its communities, although growing, are not yet too large or too suburban to be studied profitably as functional entities. Whether the communities and the clubs and the customs are just starting or are dying, as some Alaskan villages are, the interrelationships throughout the Territory and between it and the States can be studied. Migration can be stated more exactly in Alaska than, for example, in a single State.

Every real scientist accepts the necessity of prediction. And Alaska needs prediction, if it is not to become a neglected social and political jungle. It needs not only the field observer and the basic scientist, it needs also the man who will apply the generalizations to specific problems. Everyone suffers from the malfunctioning of social institutions, and some suffer from the changes that must be made. The social scientist may be unwilling to commit himself on a prediction, or he may make a mistake when he does commit himself, but we need him in Alaska so much that we can risk giving him a crack at the job.

The Study of Man

Except in the specific field of health, there is no research agency in Alaska comparable to the Geological Survey and the Fish and Wildlife Service for studying the most important animal

By Margaret Lantis, Ph.D.

of all: man himself. The Geological Survey is studying the processes of solifluction and the boundaries of permafrost. Because of its work, engineers today and in the future can build better on permafrost.

In contrast, no one is learning how to handle the processes of competition and cooperation so that there won't be a "frost-heave" in the community every summer when migratory workers come in. No one is studying the shifting boundaries between private development of a new area and government development.

A scientific discipline's usefulness depends not only on its ability to do the necessary job but on its being given the opportunity to work. Many of the natural and physical sciences have had this opportunity in Alaska; now the social scientists need their chance. I don't want to imply that they are completely absent from Alaskan research, for I know of 11 recent and current social science studies. Four are being made by economists, and others are by anthropologists, physicians, housing specialists, and church workers. Sociologists and political scientists, however, are absent.

Every frontier region has to reach a certain stage of social organization before it can support professional specialization. Each of the American frontiers in succession seems to have gone through similar stages. Alaska offers just as exciting opportunities to the sociologist or social psychologist as to the archeologist who finds there ancient cultures beautifully kept on ice. Alaska contains all the stages of modern American culture, not on ice but decidedly viable and excitable. Alaska has little deadwood in its society and few vested interests.

Ready for Study

Alaska is at the right stage of general cultural development to accept professional social study of itself. Of course, we can expect public opposition to social science in Alaska; we can also expect disappointing and inadequate work by the social scientists. It is hard enough to understand an ant colony. How much more difficult to study ants with ideas!

At Alaska's present stage of readiness, perhaps it only wants to know how big it's getting to be. Perhaps it only wants to know how

many robbers it has in order to decide how many cops it needs. Such counting of heads or sticky fingers is not enough. Instead of merely surveying the social pathology of the Territory, or of surveying anything, we need to study dynamic processes. Although Alaska is not the only new society and new economy that might be studied, and even though many processes at work there may have been observed elsewhere, it does offer a fine new opportunity that should not be missed. I suppose volcanologists did not make any stupendous discoveries from Paracutin, but I'm sure some of them managed to get to that cornfield where a little volcano was sprouting.

Socioeconomic Trend

What should we study in Alaska? Examine, for example, the socioeconomic trend of development, and consider what we must know in order to accommodate that trend, to adjust to it.

Agriculture will increase in some parts of Alaska, but as in Norway and Sweden, mines, manufactures, and fisheries can support a growing population and economy far better than agriculture. A nonagricultural region like Alaska can be economically useful in production of raw materials, in processing and manufacturing, and in provision of services including trade. Until recently, the Territory's economy has been based almost exclusively on the exploitation of natural resources: fur-bearing and oil-bearing animals, fish, minerals, and, to a small extent, timber. With the exception of fish, virtually all products were shipped out unprocessed.

Now that the Alaskan economy is getting its new start by means of a construction boom, the first requirements are for local processing plants to provide construction materials, power to run the plants, local skilled labor, and the service trades. Getting out raw materials with modern technology means few men and much heavy equipment. Processing plants and especially the service facilities require workers. A particular type of economy facilitates or even requires a particular type of society and political organization. Little enough is still known about the relations between economy, society, and politics; and Alaska is just the place to

study them. As examples, I suggest studies of the following questions as necessary, and practical:

Concepts of capital. What are the attitudes of old settlers, of newcomers, of the different native peoples toward land—land as an investment, as a place to live?

The people and their skills. What types of people are coming to Alaska? What has been their level "outside"? What skills do they have that they are not using? What new skills are they acquiring?

Community structure and political structure. What do new settlers miss most in community life and in political system? What do the native peoples miss most in their present stage of partial acculturation?

Understanding Mankind

In sum, we have three dynamic relationships to study: the people and their material resources; the people and their socioeconomic system; and the people and their political system.

There is, of course, no political system without people. One can talk about a system, but I mean the ideas that individuals live by—their unstated assumptions, their expectations, their struggles to get what they want, in a job or a place in the community. To learn about these cultural values, one does not mimeograph the kind of questions I have just phrased and then distribute a questionnaire. This is a job for professionals, and a tough job even for them.

To make life more satisfactory for Alaskans, one must study Alaska. But in undertaking the processes of behavior in any group, one understands more about mankind and contributes to basic science.

Enteric Diseases

Vital to the control of enteric diseases in Alaska is the provision of safe and adequate water supply and sewage disposal systems.

Of the 63 communities in Alaska with populations of 200 or more, only 29 have limited

water distribution systems. Only 5 have community sewage disposal facilities. In the other 223 Alaskan communities, individuals obtain water from single premise wells, community wells, rivers, lakes, lake ice, or snow fields. These communities and villages dispose of sewage through single premise systems, by scavenger service, or by dumping the collected wastes not far from the dwellings.

Contaminated water supplies and improper sewage disposal have been the major causes of the gastroenteritis outbreaks recently compiled for the period 1900–52 from records of the Alaska Department of Health, Alaska Native Service hospitals, and from other government reports and personal correspondence.

The data are incomplete in some instances because of incomplete reporting and loss of records. One case on the record does not preclude the existence of others, and sometimes only deaths were reported. No cases of bacillary dysentery, for example, were reported in 1944 from the Kuskokwim area where records give this disease as the cause of 97 deaths.

It was not until 1936 that the first public health laboratory was established for the Territory, and diagnostic bacteriological laboratory services became available to hospitals, physicians, public health personnel, and field nurses for enteric disease studies.

But the history of the outbreaks does indicate the extent of enteric diseases, such as typhoid fever, paratyphoid fever, and bacillary dysentery caused by *Salmonella* and *Shigella* organisms. Cases have been reported from Barrow to Ketchikan and from Unalaska in the Aleutian Islands to the Canadian border.

In 10 areas where hospital care, medical facilities, and transportation are available and the reporting is therefore more complete, records indicate that salmonellosis and shigellosis are endemic.

The first mention of an outbreak resembling bacillary dysentery was in 1807 in Unalaska, but until 1900 there were no medical records of

By Frank P. Pauls, M.S., assistant director, division of public health laboratories, Alaska Department of Health, Anchorage.

enteric cases in Alaska. From that date to July 1952 a total of 274 cases (24 deaths) of typhoid fever, paratyphoid fever, and salmonellosis were reported. On record for the 1937-51 period are 340 cases, including 110 deaths, of bacillary dysentery and shigellosis.

Typical Typhoid Outbreaks

Typhoid carriers have been found in the Norton Sound, Nushagak, and Anchorage areas. In 1900, two cases of typhoid fever were reported from Golovin on Norton Sound. These two persons were found to be "healthy" carriers of *Salmonella typhi* in 1941 during an epidemiological investigation of a typhoid fever outbreak in the Golovin-Elim area. And one of them, a trader who visited the villages along Norton Sound, was linked with the outbreak. From 1900 to 1941 there were 24 cases, 3 of them fatal. The carriers were placed under medical care, and no further cases have been reported from this area.

Typhoid fever may have spread to Norton Sound from the Dawson area, Yukon Territory, Canada, where an epidemic occurred in the spring and summer of 1898 during the Klondike gold rush. Deaths were reported to be from 10 to 12 a day during the epidemic. River water was indicated as the source of the infection.

Since 1936, 7 outbreaks of typhoid fever, 4 of them waterborne, have been reported from the Nushagak area, center of salmon fishing and cannery activity. During the fishing season, the Eskimo and Indian families from the surrounding villages move into crowded tent camps with no sewage facilities except convenient bushes or creek banks. They get drinking water from the most convenient pond, creek, or well. In the largest community, a local well is the town supply. Drinking water is collected by clearing away the surface debris of paper and dog hair and dipping the water out. Dogs and men have the same easy access to the well water—there is no curbing or cover. In addition, the well is at the base of a bluff in a ravine that drains the village graveyard 150 feet away. Diarrhea has been prevalent among the children, and villagers expect that some of the children will die every year from this disease.

Altogether, 42 cases (6 fatal) of typhoid fever

are on record for the Nushagak Bay area since 1936. In 1951, the mother of a child with typhoid fever was discovered to be a carrier of *S. typhi*. Several other possible carriers have been detected.

In the Anchorage area, carriers were found in the 1947, 1950, and 1952 outbreaks of typhoid fever. *S. typhi* was isolated from the 17 children and from the carrier, the mother of one of the children, in the 1950 outbreak, occurring in a congested area outside the city limits. Residents were dependent on shallow wells of 6 to 12 feet deep for water and single premise sewage disposal.

Diarrhea Prevalence

The rumors of diarrhea outbreaks that frequently sweep villages and the delayed reports that reach the Alaska Department of Health are typical of dysentery reporting in Alaska. The outbreaks commence during or shortly after the spring breakup and continue to the end of summer.

In the 1948 outbreak in the Barrow area, there were 105 cases (1 death) during a 5-month period. A field team isolated *Shigella paradysenteriae* from stool specimens of 3 cases. The following year bacillary dysentery was reported from Anaktuvuk Pass and *S. paradysenteriae* was found in 5 cases. In both outbreaks contaminated drinking water was indicated as the source.

The Unalaska bacillary dysentery outbreak in 1949 was the first opportunity for a complete epidemiological team—physician, sanitarian, and bacteriologist with field laboratory equipment—to investigate an outbreak in Alaska, determine the etiological agent, and offer sanitary and medical aid. Investigation proved the epidemic to be a waterborne bacillary dysentery outbreak caused by *S. paradysenteriae*. Recommendations were made for improving sewage disposal methods and relocation of the water supply.

The Unalaska bacillary dysentery outbreak teric diseases are Fairbanks-Nenana, Kotzebue Sound, Kuskokwim, Juneau, and Ketchikan.

In all the outbreaks, whether waterborne or foodborne, poor sanitation plays an important part. Influx of people into crowded areas increases the health hazards already complicated

by unsatisfactory basic sanitary facilities, since the newcomers bring with them their own diseases, and carriers of typhoid fever and parasitic infestations are undetected in this group.

Animal-Borne Diseases

The study of diseases transmissible from lower vertebrates to man has been carried on since 1948 in Alaska by the Arctic Health Research Center. Emphasis to date has been placed on diseases of helminthic origin.

Hydatid Disease

It has been recognized for many years that the tapeworm *Echinococcus granulosus* exists in North America and that the wolf and the moose are essentially involved in its natural life cycle. Ruminants other than the moose may also serve as intermediate hosts, and dogs and foxes often harbor the adult parasite.

Postmortem examinations of canine animals as well as the moose have disclosed that this parasite is common in Alaska. As high as 25 percent of the sledge dogs in certain villages have been found infected. The necessarily close association between man and dog in Alaska provides ample opportunity for human infection, which occurs as a result of the ingestion of tapeworm eggs eliminated in the excreta of canine animals. Living conditions in the far north often make impossible the sanitary precautions necessary to prevent human contact with the parasites.

On St. Lawrence Island, a much more pathogenic form of *Echinococcus* has been found. Its natural life cycle involves the arctic fox and at least two species of small, mouselike rodents; thus, the development of an effective control program would not be feasible should this tapeworm become established on the mainland. Dogs are as readily infected through eating

infected rodents as are foxes, and it is probable that most of the human infections are attributable to eggs disseminated by infected dogs. It is hoped that introduction of this disease into continental North America can be prevented by rational quarantine measures. Stringent control of dogs, particularly on St. Lawrence Island, is recommended. An educational program is badly needed to inform the people of the importance of this disease.

Trichinosis

An investigation of the prevalence of trichinosis in Alaskan mammals was undertaken in 1949. It was found that a wide variety, including bears, dogs, wolves, foxes, and wolverines, often harbor *Trichinella spiralis*. The parasite was also recorded from tree squirrels. A white whale was found infected, and larvae were recovered from hair seals. It is probable that trichinosis is transmitted to man from bears more often than from any other group of Alaskan mammals. Polar bears are sometimes eaten under conditions which preclude adequate cooking. The problem of trichinosis, however, is not considered a serious threat to human health in Alaska.

Diphyllobothriasis

A survey of possible terminal hosts of cestodes of the genus *Diphyllobothrium* has disclosed their occurrence in a variety of mammal species, including, besides man, bears, dogs, and foxes. They have also been observed in gulls and eagles. No comprehensive survey of the fish intermediate hosts of this tapeworm has been made, but it is obvious that in certain areas most trout exceeding 6 inches in length are infected. Some contain so many plerocercoids that fishermen consider them unfit for food.

No attempt has been made to evaluate the importance of *Diphyllobothrium* to human health. In regions where fish make up a high proportion of the diet (for example, lower Kuskokwim-Yukon country) incidence of human infection is high. Treatment so far has little value because of the probability of immediate reinfection.

If it can be established that a single species of *Diphyllobothrium* occurs in the various car-

By Robert Rausch, Ph.D., parasitologist, Arctic Health Research Center, Public Health Service, Anchorage.

nivores, birds, and man, the problem of control will be complex. Infected birds particularly would serve to maintain infection in fish. Much work remains to be done on this problem.

Diseases of Nonhelminthic Origin

Important in Alaska among diseases of nonhelminthic origin is rabies. Known to be enzootic over most of the Territory, it constitutes an ever-present threat to public health. Almost every year there is an outbreak among wild or domestic canids somewhere in the Territory, but so far it has not been reported to attain epizootic proportions.

The great numbers of stray dogs to be found at any time around the larger towns, particularly Anchorage and Fairbanks, constitute an animal reservoir through which rabies might spread rapidly if once introduced. There is no provision for dog control outside the limits of incorporated towns, and control within their limits is far from adequate. No program for vaccination of dogs has been established, and there is little expectation of any.

Tularemia in man is rarely reported in Alaska, although it has been known for several years that it does occur. With increasing sport hunting of hares in the populated portions, this disease may attain some importance.

Various other diseases—brucellosis, leptospirosis, ratbite fever—have been investigated to some extent in Alaska, but their present status is indefinite. It is anticipated that these diseases and many others will receive attention in coming years.

Hydatid Disease Control

PHR Hydatid disease is a global problem, representing a serious public health menace on every continent. Recent studies have shown that the disease is spreading from major foci of infection and

have also discovered endemic areas that were heretofore unrecognized.

Noting the importance of hydatidosis both as a human infection and as a cause of losses in food supplies, the Third World Health Assembly (1950) requested the World Health Organization "to lend technical assistance for its eradication upon request of government authorities." In the Western Hemisphere, the Pan American Sanitary Bureau has provided assistance and international coordination to member governments in their antihydatidosis activities. Control efforts emphasize anthelmintic treatment of dogs, centralized slaughtering with sanitary waste disposal, and public health education.

Control Points

The cycle of the parasite *Echinococcus granulosus* may be interrupted by prevention of infection of the primary host (dogs, foxes, wolves, and so forth) and by prevention of transmission from the canine host to other animals.

Proper disposal of the organs of animals containing hydatid cysts will prevent the infection of dogs. Organized meat inspection to accomplish this is not practicable in all parts of the world. Furthermore, meat inspection would have no effect upon the cycle of the hydatid parasite when the secondary hosts are wild animals, a situation which obtains in Alaska.

Canine Control

It therefore appears that the most practical method of interrupting the cycle of this parasite is to attack it in its primary host, the canine. In dogs, mass deparasitization may be practiced. The great strides in hydatidosis control in Iceland are attributed in large measure to enforced limitations on the number of dogs and the periodic anthelmintic treatment of all dogs. A similar approach has been followed in Argentina, where antiechinococcal treatment of dogs is given free. This work was begun in Patagonia in 1948 and has since been carried on extensively in several other parts of Argentina. Large-scale antiparasitic treatment of dogs has also been practiced in southern Brazil.

Mass deparasitization of dogs requires community organization and enlightened public cooperation. Dog owners must be encouraged to have their dogs treated, and individual action

By Benjamin D. Blood, D.V.M., M.P.H., chief, veterinary medical service, Pan American Sanitary Bureau, Washington, D. C.

should be supplemented by public clinics. The dramatic action of the most widely used deparasitization drug, which purges within a few minutes, affords opportunity to demonstrate to a dog owner the existence of parasites in his dog.

Obviously mass deparasitization cannot be practiced on wild canids nor on stray dogs. However, the methods used to apprehend and eliminate the ownerless dogs may be equally applicable to the wild carnivores which carry the adult tapeworm.

A Distemperlike Disease

PHR Death or incapacitation of a large proportion of a community's dogs is a real disaster in the far north.

When an Eskimo community is deprived of its dogs, it loses the principal means of transportation. The Eskimo lives by hunting, and his dogs are his only draft animals. The loss of dogs also impairs national defense in the northern perimeter, since without a dog team extended ground scouting is impossible in the winter.

Modern transportation has complicated the control of animal diseases in Alaska as it has human diseases. For example, a New York City dog can reach Barrow by air express in less than 30 hours. This hypothetical dog may have had rabies immunization and may have been passed as "healthy" by a thorough veterinary examination. Yet, if he travels by air, he can become acutely ill in Barrow from a disease contracted in New York.

Point Barrow Epizootic

A severe epizootic of canine distemper, or a clinically related disease, occurred at Point Barrow, Alaska, in the fall of 1951 and continued into the winter. About half the dog population, an estimated 500 dogs, died or had to be destroyed because of the effects of the

disease. Administration of penicillin and streptomycin and destruction of incapacitated dogs probably hastened the natural end of the epidemic. The distemper is continuing enzootically in Barrow.

Early in July 1952, a similar or identical disease that may have been carried from Barrow by wildlife appeared among the dogs at Anaktuvuk Pass, an isolated village 200 airline miles from Point Barrow across the Arctic Slope. In the summer this terrain is traversed only by wild animals. In the winter a trip between the two places is seldom made.

The symptoms of the disease observed in the dogs at Barrow and Anaktuvuk were about the same as those of the canine distemper caused by the Laidlaw-Dunkin virus. The extreme virulence of the distemper seen in Barrow and Anaktuvuk dogs was notably different from that ordinarily seen in the States.

Chorea and other neurological disorders in the Alaskan dogs commonly coexisted with the acute symptoms of nasal and eye discharge. Neurological symptoms—hyperexcitability, chorea, paresis, and sometimes convulsions—do not ordinarily occur early in the course of the disease in the States. The course of the disease in some of the Barrow dogs was peracute—death occurred within 24 hours of the onset of symptoms. In some instances, entire teams collapsed while out on trek and had to be destroyed.

Immunization Project

Immunization studies were started in August 1952 at Barrow, Anaktuvuk, and Wainwright to evaluate the possibility of controlling the disease by blanket or partial inoculation with attenuated canine distemper virus vaccine. All dogs available at Anaktuvuk (about 190) were inoculated to test blanket administration of attenuated virus vaccine.

At Barrow, some of the dogs brought to the immunization clinic were given vaccine and others were given a placebo. Selection was made by a random number system. Although response was poor—only 121 dogs were brought in—it may be possible to learn how vaccinated dogs and litters, with half the pups vaccinated, fare in an enzootic area.

By Karl R. Reinhard, D.V.M., veterinarian, Rocky Mountain Laboratory, Public Health Service, Hamilton, Mont.

The same random inoculation system was used on the 178 dogs brought to the clinic at Wainwright, a village possessing about 200 dogs. Two dogs had died the previous winter of a disease reported as similar to that in Barrow. Half the dogs were immunized to determine if this immunization level would induce pack immunity and protect the dogs of Wainwright against future extension of the disease from Barrow.

Mosquito Control

PHR Mosquito control among Alaskan civilians is still rather primitive. It is almost wholly unorganized; is only slightly mechanized; and is improvident in that only small stores of materials and equipment are maintained. Civilian control is strikingly primitive in that the only measures used are those that give temporary relief. Little effort is made to prevent future attacks by destroying insects in vulnerable but nonbiting stages. Little is done on more than an individual or single family basis.

The military control program has achieved a high degree of organization and mechanization. Airplane spray is stored in strategic locations. Frequent estimates of the insect populations at widely separated bases are sent to the headquarters at Elmendorf Air Base. When the severity of the mosquito attack warrants, a spray team in a specially equipped C-47 is dispatched to do the necessary spraying.

The civilians, largely dependent on their bottles of repellent, lack organization and must pay for their projects. Even though the Territory is generally prosperous, the demand for capital is great. When the well is not yet dug and there are no windows in the house, insect control is apt to rate a low priority on the list of projects.

By Charles S. Wilson, M.S., entomologist. Arctic Health Research Center, Public Health Service, Anchorage.

Obstacles to Control

Many Alaskans would be willing to spend large amounts for mosquito control by stateside standards, but without organization they can do little.

For example, an aerosol spray unit for protecting single premises was an early product of the Arctic Health Research Center. In actual operation, this apparatus seems suitable for single family use. The problems of manufacture and supply have not yet been solved, however. Without the protection of a private patent, no manufacturer wants to produce the special nozzles required. Without an assured market, merchants are reluctant to stock the airplane type of spray solution required. If a market were available for only 50 units, the picture might change, but at present the device is used chiefly by the Air Force and by some nonprofit summer camps. Both groups are sufficiently organized to obtain insecticide before the mosquito season. The Air Force makes its own nozzles. The summer camps obtain them from the Arctic Health Research Center in return for cooperation in testing.

Around Fairbanks and Anchorage are civilian areas where many military personnel live off-post. These would benefit from an extension of the military spray operations. Although the organization of cooperative projects would seem to be advantageous, military regulations require: first, waiver of claims; next, right of entry to any private property sprayed by military planes; and third, contribution toward the cost according to the interest of the parties concerned.

Spraying property without legal authorization is trespass. Direct negotiation with each landholder for permission to spray may be possible in isolated areas, but it is practically impossible in the residential and suburban districts of Fairbanks and Anchorage. Some means must be found for obtaining blanket authorization and general assessment of the costs before spray programs can be developed for urban districts. Organization will certainly be called for if the advantages of airplane sprays are to be utilized.

The Alaska Department of Health has authority to spray private property when there is

threat of epidemic. Annually recurring mosquito seasons are not epidemics within the usual meaning of the term, although it may be argued that the itching sores resulting from insect attacks constitute diseases. However, the department has too many serious problems definitely falling within its province to be likely to seek authority for compulsory mosquito control.

Future Projects

The present program of insect control of the Arctic Health Research Center is largely devoted to development of methods and equipment for spraying with light airplanes such as those used by "bush" pilots. The chance of success seems fairly good, and if suitable methods and equipment for light planes are developed, the possibilities of acceptance and use appear to be very good. The greatest need, however, is for protection of the homesteader and isolated worker.

With bush pilots in the mosquito control business, the work will be mechanized, and the necessary stores of insecticide and equipment will be maintained by the pilot or his organization so that the word "improvident" will no longer apply. If costs can be made sufficiently low to permit wide use of airplane sprays, the necessary organizations will almost certainly develop. Then the advantages of mosquito larvicide may be utilized, attacks on the vulnerable larvae of black flies will become possible, and Alaskan insect control will have emerged from its primitive condition.

Mastoiditis

PHR When large segments of a country's population are afflicted with a disease that interferes with education and ability to earn a livelihood, this disease becomes a public health problem.

In Alaska, mastoiditis is a public health problem. An incomplete survey of the population indicates that about 3,000 persons are afflicted with chronic mastoiditis of one or both ears.

Costs for surgical treatment of mastoiditis amount to about \$1,000 per patient, including

costs of transportation to a hospital, of hospitalization, of drugs, and of residence in a convalescent home until recovery. When hearing has been so badly impaired that even a hearing aid is not effective after surgery, persons must be sent to speech centers, at a further expenditure of money for transportation, subsistence, and tuition.

The great prevalence of mastoiditis in Alaska is due to many factors. It is estimated that 90 percent of the cases are among the Eskimos, Indians, and Aleuts. These people have become so inured to hardships that they tend to underestimate the importance of any ailment that is not immediately and obviously a threat to life. Other reasons for the prevalence in Alaska of this now "obsolete" disease are the distance of these people from adequate medical care; ignorance of the importance of the common cold, of tonsillitis, and otitis media and of how to recognize and treat these afflictions; and the lack of readily available hospital beds and of funds for carrying out simple, efficacious programs of prevention and treatment.

Proposed Prevention

Educational efforts must be directed to non-medical persons in the small villages who are interested in the health of their fellow citizens. They should be taught the value and proper use of simple nasal decongestants.

The nurses of the Alaska Department of Health and the Alaska Native Service should be taught the proper use of intranasal medications and of an agent applied topically in the external ear. They should also recognize the importance of removing tonsils and adenoids from children who have demonstrable hearing loss during head colds. The nurses should be required to report the names and other data on all patients who have a history of earaches or hearing loss with common colds, repeated attacks of otitis media, chronic otitis media, and chronic mastoiditis. For cases of chronic mastoiditis, which is recognizable by its continual

By Milo H. Fritz, M.D., Anchorage, consultant in ophthalmology and otolaryngology to the Alaska Department of Health.

discharge and extremely foul odor, the nurses should be taught the value and use of glycerite of hydrogen peroxide in keeping ear cavities clean and sweet and also that it does not cure the underlying pus-forming or suppurative process.

Itinerant physicians working for both government agencies and physicians in more or less fixed installations who have an orbit of activity in surrounding towns and villages should be taught how to administer a general anesthetic in the field and how to remove tonsils and adenoids.

Coordination With Universities

Another physician and I have gone to small villages from time to time and removed from 20 to 30 pairs of offending tonsils and adenoids in a period of 2 or 3 days. Two or three summers of this type of activity with university-sponsored physician-anesthetist teams and equipment would go far in reducing the continued development of cases of chronic mastoiditis.

Two universities (Duke University and University of Oregon) have participated so far in a program of sending members of their resident staff to Alaska for 6 months' training under supervision of the consultant certified by the American Boards of Ophthalmology and of Otolaryngology. It is hoped that other university medical schools may be encouraged to include such training as part of their formal residency programs.

Two Water Systems in Northern Canada

PHR Water works engineers in Northern Canada and Alaska are faced with unique design and maintenance problems. Preventing the freezing of water and sewer lines is paramount to design and maintenance in northern climates, a factor which raises both construction and operating costs many times higher than those in more temperate regions. Avoiding the winter cold,

utilizing the sun's radiant heat in winter and summer, yet keeping excavation to a minimum and maintaining the lowest possible maintenance expenditures are some of the problems to be met. Temperature variations of different types of soil under various moisture conditions in disturbed and undisturbed ground and in various climatic regions need to be determined.

Two all-weather underground water supply systems installed within the last few years in the Northwest Territories of Canada have proved successful.

Yellowknife

One system is at Yellowknife, where the mean annual temperature is 22° F., and the top of the permafrost is 10 feet or less from the surface of the ground. Annual precipitation is 10 inches, and snowfall is sparse. Water is pumped from a bay, chlorinated, heated, and circulated through a grid system 3,500 feet from the pumphouse. Part of the water is returned to the pumphouse for reheating and recirculating.

Each main and house connection has a return line beside it. Water lines are of cast iron pipe, laid at 5 feet 6 inches minimum cover and to grade for drainage. Both 6-inch supply and 4-inch return mains, which are side by side, are insulated with approximately 1 foot of compacted moss on the top and sides and from 0 to 2 inches underneath. Extremely fine sand with granite outcroppings covers the area.

Meters and recording thermometers are located on discharge and return water lines in the pumphouse, and thermometer wells are located in the mains at the manholes. The water is heated from November through May. Originally installed in the pumphouse were two 60-hp. and one 80-hp. return tubular boilers, but one firebox and diffuser has been reduced to give roughly 15 hp. capacity. Under normal conditions, two ¾-inch copper lines are used

By Stanley S. Copp, M.S., sanitary engineer, Department of National Health and Welfare of Canada, Edmonton, Alberta.

for heating the water, one injecting into the recirculation line and one into the intake well. Outgoing water from the pumphouse is maintained at about 41° F. During March, when 80 percent of the outgoing water is recirculated, the temperature of the return water is about 40° F. On June 30, 1952, 1 month after heating was discontinued, the discharge temperature was 50° F., and temperature of the return water was 46° F.

Of the 37 fire hydrants, all of the dry barrel type, on the grid system, 8 froze last year. The most serious freezing occurs when circulation fails and the bottom of the hydrant freezes, but this happens infrequently. Caps and spindles at the top and at the drain opening at the bottom freeze often. Above-ground freeze-ups are thawed with blow torches; those below ground, by placing a fire pot in the manhole box overnight. Alcohol antifreeze is applied to caps, packing, and so forth, and hydrants are checked twice a week.

Five major breaks caused by frost action in the winter of 1952 were repaired without interruption of service. Excavation of breaks with jackhammers takes about 2 weeks per hole because of the hardness of the frozen ground. Bits are dulled and broken at about the same rate as in breaking concrete. Powder cannot be used because of the proximity of pipes, and holes cannot be backfilled until the frost is gone. Any interruption of service longer than one-half hour results in freeze-ups. None of the 142 service connections located at an average depth of 5 feet were frozen under normal operating conditions.

Fort Smith

About 175 miles farther south at Fort Smith is a system which preheats the water and utilizes bleeders at dead ends. The settlement has a mean annual temperature of 25° F. The soil is a fine sand.

Two intakes drilled horizontally through 40 feet of solid rock into rapids on the Slave River supply water to pumps on the edge of the river. From there, the water is pumped to a treatment plant on the top of the bank. Alum and soda ash are added, and the water is spirally mixed upward, settled, filtered, chlorinated, and stored in a reservoir under the plant. The

treated water is then heated and pumped through a pressure tank to the distribution system.

Transit pipe is used for the distribution system, which is laid at an average depth of 10 feet and a minimum depth of 8 feet. Minimum depth for house connections was specified for 8 feet, but some are laid at only 6 feet and are frozen several times during the cold weather.

The temperature of the river water varies from 32.8° to 65° F. In January, water leaving the plant at 42° F. is cooled to 35° F. at the end of the system. On April 7, 1952, the 4-inch main at the end of the system froze, disrupting two services. The frost penetrated 14 feet at this point. The two intakes from the river froze, and a gasoline pump had to be used to pump water over the ice to the wet well. Several house connections were frozen for a short period, two for more than a day.

Conclusion

Permafrost, which reaches nearly to the surface at Yellowknife, is not the insurmountable obstacle it was once considered to be. It is hoped that these two experiences may lead to less costly systems which permit other supplies to be installed and operating expenditures lowered. Installation costs may be lowered by consolidation of settlements so that lengths of water lines may be kept to a minimum and expenditures shared. With the installation of more water supply systems, the northern areas may become more developed and modernized, and waterborne epidemics may be reduced or eliminated.

Water Pollution Studies

Comprehensive physical, chemical, and biological investigations of the waters of Alaska were initiated by the Alaska Water Pollution Control Board in the summer of 1951. New industry

By Amos J. Alter, C.E., M.P.H., administrator, and William L. Porter, M.P.H., chief of field investigations, Alaska Water Pollution Control Board, Juneau.

and an increasing population in Alaska, as well as a territorial-wide awakening to the health and economic threat of polluted streams, coastal waters, and lakes, have prompted Alaska to plan for the orderly use of her waters. Alaska is in a strategic position for practicing preventive water pollution control rather than the more expensive corrective control.

Ward Cove Study

In order to develop the water resources of Alaska, careful and complete investigation of water assets and liabilities and logical matching of type and extent of water use must be undertaken. The first attempt to evaluate water assets and liabilities is being made at Ward Cove, located on Tongass Narrows about 5 miles northwest of Ketchikan. The Ketchikan Pump Company is constructing a pulp mill at this location. The cove is 1 mile in length and at mean lower low water tide it contains about 25,500 acre-feet of water. It is surrounded by heavily forested mountain slopes. Rainfall averages about 150 inches annually. Discharging at the head of the cove is Ward Creek, a swiftly moving stream dropping quickly from the mountain slopes to the cove.

Observation of the following characteristics of water in the cove was begun October 1, 1951, for completion on September 30, 1952: types and numbers of marine plants and animals; water temperature, turbidity, and color; tidal movement and exchange; fresh water discharge into the cove; type, strength, and general characteristics of wastes entering the cove; dissolved oxygen concentration, percentage of oxygen saturation, and 5-day biochemical oxygen demand; most probable numbers of coliform bacteria; total solids, dissolved solids, ignited dissolved solids; and pH, chlorides, sulfates, iron, magnesium, and calcium.

Preliminary Report

Almost 4,000 physical, chemical, and biological examinations were completed by August 7, 1952. Calculations based on the data collected will reveal the degree of waste treatment and/or dilution necessary for orderly use of the waters of the cove and will provide a background of basic data necessary for later evaluations. A preliminary review of the observations presents interesting trends.

Chemical. Dissolved oxygen concentrations during the winter and spring were generally 80 percent of saturation or over. During the summer months the upper water strata were supersaturated during the day as a result of biochemical photosynthesis. There was a decrease of dissolved oxygen in the lower depths during the fall to the extent of a noticeable oxygen sag.

Chlorides, sulfates, alkalinity, and calcium varied inversely as the water temperature; pH varied directly as the water temperature. No trend is yet apparent for solids, magnesium, and iron in analyses of samples from October 1951 to January 1952.

Biochemical Oxygen Demand. The biochemical oxygen demand (B.O.D.) was generally below 0.5 ppm except during July and August. At that time it increased to over 1 ppm.

Physical. Temperatures of surface waters ranged from 4° C. in March to 16° C. in August, and from 5° C. in March to 10° C. in August at the 100-foot depth. Turbidities ranged from 0.32 to 3.2 ppm. Color was generally less than 5 ppm.

Biological. There is abundant marine life on the shore, on the bottom, and in the waters of the cove.

Hydrological. The fresh water current from Ward Creek has little effect on the cove waters except during or near flood run-offs, and then it is limited to the top few feet of surface water near the creek mouth and to an area of from 100 to 200 feet in width through the center of the cove.

Nearly all the movement of the tidal waters to and from the cove is surface movement above mean lower low water. This condition of little or no current at lower depths extends into Tongass Narrows.

Approximately 95 percent of the dissolved oxygen replaced by diffusion to the cove waters takes place above 15 feet below lower low water. The two important sources of reoxygenation of cove waters are the tidal exchange and diffusion above mean lower low water. Any large biochemical oxygen demands at the lower depths would probably result in a septic condition because at these depths oxygen would be replaced slowly. The most critical period with regard to maintaining an adequate dissolved oxygen

concentration was during the period of highest water temperatures, from July 31 to August 7, 1952.

Anchorage Food Study

PHR Alaska is almost completely dependent on long supply lines from the west coast of the United States. Their possible disruption in times of emergency must be considered in civil defense planning.

To obtain estimates of actual food consumption and to compare Alaskan food habits with those of the continental United States, Anchorage and its vicinity were surveyed in 1950 and 1951. Because of the large numbers of military dependents and transient workers in the area, no reliable estimates of the civilian population were available to serve as a population base for the survey.

Food Consumption

Anchorage residents eat well. But Alaskan food habits differ in several ways from those in the States. Food costs are high in Alaska, but wages and salaries are high also and may compensate for the price increases. The higher costs may be disproportionate for some types of food. Perishable foods, and some items not ordinarily considered perishable, may be of poor quality. Finally, the population has an unusually large proportion of young people.

Of milk products other than fresh milk, two-thirds of Anchorage consumption is canned milk, almost five times the average consumption in the States. While consumption of milk and milk products in Alaska is 65 percent of that in the States on a retail weight basis, consumption on a whole milk equivalent basis is 84 percent of that in the States.

Egg consumption is only slightly less. The price of eggs increases in the following order: boat, airborne, local.

Frozen meat, poultry, and fish are shipped by boat. Meat and fish supplied from local sources are about two-thirds wild game and fish, with moose, caribou, and salmon predominating. Meat consumption is unexpectedly high, possibly because meat prices on a percentage basis may not be as high as those of other foods when compared with prices in the States. The high meat consumption compensates to a considerable extent for the low intake of milk.

The consumption of butter and margarine is almost identical with that in the States. However, only one-fourth as much bacon, salt pork, and lard is eaten in Anchorage, probably because of the instability of these products. Use of shortening other than lard is somewhat greater in Anchorage.

The consumption of potatoes in Alaska is understandably high, since prices of this vegetable, particularly the local product, are quite reasonable. Citrus fruit and tomato consumption is low. Consumption of other fruits and vegetables is almost equal to that in the States. Less grain products are eaten in Anchorage, but more sugar compensates for this.

Civilian food consumption was determined by a census of food imported by rail, by truck, and by airplane, and by an estimate of local production in 1950. Direct air shipments, which consisted of meat, produce, and eggs, were actually enumerated for one airline and estimated for another. Truck shipments supplied only a few grocers, and the amount shipped was estimated from the gross sales of these retailers. Distribution of truck shipments into food classes was assumed to be the same as that of rail shipments since both were shipped by boat to Alaska.

The amount of food shipped by rail was estimated by sampling the records of the Alaska Railroad. To determine food classes, 24 of the 126 ships with food consigned to Anchorage in 1950 were selected as a sample with regard to season and type of ship. Every food item, in all more than 5,000, on the ships' manifests was recorded and tabulated to furnish the sample from which the total rail shipments were estimated.

The Alaska Agricultural Experiment Station estimated local agricultural production, and the

By Edward M. Scott, Ph.D., biochemist, and Edward S. Weiss, M.P.H., statistician, Arctic Health Research Center, Public Health Service, Anchorage.

Fish and Wildlife Service estimated wild game and fish consumption.

Food Supplies

The amount of food stored in Anchorage was also determined to provide an estimate of the average period of storage before consumption and of the length of time food stores would last if supplies were cut off.

Dollar value inventories of all retailers' stocks were compiled as of January 1, 1951. A representative sample of retail inventories was selected. The items in each sample inventory were actually enumerated to provide a basis for calculating total food class inventories from total dollar value inventories. Supplies of wholesalers and miscellaneous food handlers

were also enumerated. Those of restaurants were estimated from a sample of dollar value inventories.

The average storage life of imported foods was found to be 36 days for all food classes. For fresh and frozen meat, poultry, and fish it is 21 days; grain products, 76 days; dairy products excluding butter, 34; canned citrus fruit and tomatoes, 55; and other canned fruits and vegetables, 82.

These results indicate that in the event of complete stoppage of normal supplies to Alaska, there would probably be enough staple foods to last until some emergency method of supplying food could be set up. However, many perishable items would become unavailable almost immediately, necessitating some substitutions.

Laboratory Diagnosis of Trichophyton Infections

PART I. Ectothrix Infections of the Beard and Scalp Caused by *Trichophyton mentagrophytes* and *Trichophyton faviforme*.

PART II. Endothrix Infections of the Scalp Caused by *Trichophyton tonsurans* and *Trichophyton violaceum*.

35 mm., sound, color, Part I—13 minutes; Part II—10 minutes, 1952.

Audience: Laboratory technicians (bacteriologists and mycologists), State and local health department laboratory directors, medical and veterinary students, dermatologists, and physicians and nurses interested in this problem.

Available: Loan—Public Health Service, Communicable Disease Center, 50 7th St., NE., Atlanta 5, Ga. Purchase—United World Films, Inc., 1445 Park Ave. New York 29, N. Y.

These films are designed to aid in teaching the procedure for identifying the etiological agent responsible for certain types of ringworm infections involving the hairs of the scalp and bearded areas. The preliminary procedures and final observations by which the medical technician (bacteriologist or mycologist) or dermatologist may isolate and identify the

Characteristic suppurative lesions caused by ectothrix *Trichophyton*.

Microscopic mount for *Trichophyton mentagrophytes*.

responsible fungi are depicted.

The films show the possible sources of *Trichophyton* infections, the method of examining the patient and of obtaining and examining the clinical material. They show the cultural methods used for isolation and the techniques for identifying the fungus agent when it is isolated. Part I is concerned with ectothrix infections, and part II with endothrix infections.

The Composition of the Sanitary Engineering Profession

The sanitary engineer is largely a North American phenomenon, the result of efforts to protect health and prolong life through an attack on the environmental influences which cause disease.

In order to determine the nature of the sanitary engineer—who he is, where he works, what his activities are, his age, professional and educational background—an analysis was made by the Division of Engineering Resources, Public Health Service, based upon data loaned to the division by the American Public Health Association. The data were originally collected by the American Public Health Association for the purpose of establishing the Roster of Public Health and Sanitary Engineers.

The survey was conducted from the spring of 1949 to October 1950 by a self-coding questionnaire. A total of 10,757 questionnaires were sent to persons whose names were obtained from the membership lists of various engineering associations and professional engineering registration lists. There were 6,368 respondents of whom 4,933 felt that they met the definition of a sanitary engineer as set forth by the National Research Council. Following careful editing with respect to educational and professional qualifications, 4,116 remained as the base group for the study.

On the basis of the survey it is estimated that there were, in 1950, 5,000 sanitary engineers in the country—33.2 per million population. Of those who participated in the survey, two-thirds devoted more than three-fourths of their time to sanitary engineering activities (discussed as group I); about 19 percent between 50 and 75 percent of their time (group II); and 19 per-

cent less than 50 percent of their time (group III).

A relatively small proportion (35 percent) of sanitary engineers has a formal sanitary engineering education. There is a considerable rise in the educational level, as is seen in the shift toward more sanitary engineers in the "master's" and fewer in the "no degree" levels in the younger age groups. Sanitary engineers in group I are better educated than those in group II and III. In group I, 28 percent have reached the master's level; for groups II and III the percents are 13 and 11, respectively.

The civil engineering curriculum has provided the basis for the undergraduate education of most of the members of the profession. In regard to experience, broadly speaking, almost half of all sanitary engineers have obtained a significant part of their professional experience outside the field.

The various branches of the engineering profession have between 1.6 and 18.3 percent of their members engaged in research activities. Therefore sanitary engineering, with only 1.9 percent of its personnel doing research, ranks low in this respect.

The four leading types of activity are public health, designing, consulting, and municipal. About 80 percent of all sanitary engineers are in some way connected with water and sewage programs.

The data on the characteristics of the sanitary engineering profession are given in the form of tables, charts, and other graphic devices. Age, numbers, education, types of degrees, activities, and professional area are covered by these statistics which are presented in individual tables or correlated in various combinations.

Cancer Morbidity Series

Cancer illness among the residents of Birmingham, Ala., and Detroit, Mich., is covered in publications 8 and 9 in the Cancer Morbidity Series. Both cities showed an increase in cancer incidence in the past 10 years, according to the reports.

In the Birmingham area the incidence rate during 1948 was 71 percent greater than in 1938 and the mortality rate was 24 percent greater. The incidence increase in Detroit in the 10-year period was 59 percent. These increases in incidence may have been due in part to better reporting by physicians, improvements in diagnostic and case-finding methods, and aging of the population.

The Birmingham survey showed that of all the cancer cases diagnosed when the disease was localized, 87 percent survived 12 months. In cases not discovered until regional involvement had taken place, 66 percent survived 12 months, and in cases not diagnosed until remote metastasis had occurred, only 33 percent survived a year.

Similarly, in Detroit, 78 percent of cases of early diagnosed cancer, 54 percent of those discovered after regional involvement, and only 22 percent of cases diagnosed after remote metastasis survived 1 year.

Office of Defense Mobilization Pamphlets

Maintaining the worker's health and the employability of women, the elderly, and the disabled are subjects covered in four Office of Defense Mobilization pamphlets.

"The Worker and His Health" estimates sickness absenteeism in industry to be 400-500 million man-days a year, an equivalent of almost 2 million men absent from their jobs for a year. More than 90 percent of the illnesses have nonoccupational causes. Experience in plants, the pamphlet states, has shown that in-plant health services can reduce losses from sickness absenteeism by one-third to one-half. The value of in-plant health programs is stressed, and steps for their development are suggested. Local health departments, medical and dental societies, visiting nurse associations, employer associations, labor organizations, and other firms with in-plant health services are referred to as the best sources from which to obtain information on how to initiate an in-plant health program.

Women, and handicapped and older workers have production and safety records as good as or better than other workers, the pamphlets, "A Job for Women," "The Disabled Can Work," and "Production at Any Age," claim. Increasing numbers of women are finding employment in industry. The Bureau of the Census estimates that 19 million women, or 30 percent of all workers, are in the civilian labor force today.

"A Job for Women" outlines the importance of matching the woman worker's physical, mental, and emotional capacity against the demands of the job to assure successful placement.

"The Disabled Can Work" states that through rehabilitation many physical and mental handicaps can be eliminated or reduced to enable

workers with disabilities to meet demands of selected jobs. When the disability is properly treated, the person trained for and placed in the right job can meet the requirements as well as anyone. Advances in medical knowledge, improvements in prosthetic devices, development of specialized rehabilitation centers, and the establishment of vocational rehabilitation and placement programs have made it possible for thousands of disabled men and women to resume active lives and enter the labor force as self-supporting citizens. The plant medical department plays an important part in aiding the placement of the handicapped worker.

"Production at Any Age" cites the older person's need of productive activity with pay checks. Industry, the community, and the Nation have a stake in the usefulness and economic productivity of older workers, the pamphlet states in emphasizing the necessity of breaking down current prejudices against hiring this group. Industry can help provide much needed information for proper placement of older workers through careful study of job requirements, conditions of entry, and the productivity of older workers. In-plant health services can also contribute much to the health and productivity of the older worker, through periodic physical examinations and other preventive services. Similarly, benefits would accrue to all the workers from the preventive services of such in-plant health plans.

Clean Water Pamphlets

"Till taught by pain men really know not what good water's worth." This quotation from Lord Byron prefaces each of four pamphlets which deal in a personalized way with the pollution problem in its respective river basin area.

Based upon the longer technical reports of the cooperative State-Federal drainage basin surveys, the pamphlets present the story of pollution in terms of the interests of the people in each area. They describe the cities which are situated along the rivers, their industries, and what each is contributing to the pollution problem in terms of dangers to health, agriculture, recreation. The pamphlets tell what the cities are doing about the pollution problems—which are and which are not treating their sewage. And finally they tell what the people must do to correct the problem.

These four pamphlets are part of a group of 15 that are being prepared in connection with the longer drainage basin surveys.

Keeping Our Hospitals Operating— A Study of Supply and Equipment Requirements

Results have now been published of the study undertaken by the American Hospital Association and the Public Health Service to determine the maintenance, repair, and operating (MRO) requirements for civilian hospital equipment and supplies.

The operating workload of the survey was carried principally by the Divisions of Civilian Health Requirements and Hospital Facilities of the Public Health Service. Survey questionnaires were mailed to all continental United States non-Federal hospitals of 15-bed size or larger that were on the American Hospital Association's mailing list, including nonmembers. Presented in the report are the estimated requirements for 585 hospital items, based on replies from over 2,600 hospitals of every type and size throughout the country. The number of hospitals which returned replies represents about 55 percent of the hospitals queried. Long-life items are reported in terms of national 5-year requirements; short-life items in terms of national 1-year requirements. A detailed breakdown of the survey data is included for further use by researchers in this field. The survey is the most comprehensive ever undertaken to determine what equipment and supplies are required by hospitals.

During a period of mobilization, accurate knowledge of essential civilian needs is necessary for making proper decisions and allocations respecting any segment of our economy, the report notes. Hospital specialists, who had personal experience with allocations during World War II, favored the study, because of the handicaps that they previously had encountered.

In summarizing the survey, the introductory section of the report cites the uses of the estimates as follows:

1. By agencies of the Government—in preparing and analyzing

proportionate civilian and military hospital requirements in this field.

2. By distribution agencies—as a factor in distributing critical materials.

3. By hospital administrators—in conducting intensive studies of institutional operation.

4. By the manufacturing industry—as a factor in considering adequacy of productive capacity.

5. By the combined manufacturing and distributive industries—in designing distribution operations.

The MRO study of hospital equipment and supplies is a part of the overall surveillance of supply-and-demand relationships with respect to health material that is being conducted by the Public Health Service.

Keeping Our Hospitals Operating. A study of supply and equipment requirements. (Public Health Service Publication No. 272) 1953. 191 pages; tables. 45 cents.

Community-Wide Installation of Household Garbage-Grinders

This is a joint publication of the Indiana State Board of Health and the Public Health Service prepared in answer to many requests from city governments, sanitary engineers, and the plumbing industry for information on the results of the Jasper, Ind., experiment. In December 1949, Jasper became the first municipality to undertake the elimination of garbage collection through the installation of home garbage-grinders. The project was begun after an epidemic of hog cholera resulted in the refusal of contractors to collect Jasper's garbage. In the 18-month period of this study 900 household garbage-grinders were installed, servicing 75 percent of the population.

The report is preliminary, since the restaurants and food service establishments have not as yet installed garbage-grinders. In addition to background information on the development of the project it discusses the effect on the sewerage system, water consumption, refuse

collection and disposal, fly densities and rodent infestation.

Erganian, George K., Belter, Walter G., Graber, Ralph, C.: Community-Wide Installation of Household Garbage-Grinders. (Public Health Service Publication No. 224) 1952. 41 pages; illustrations, tables, charts. 20 cents.

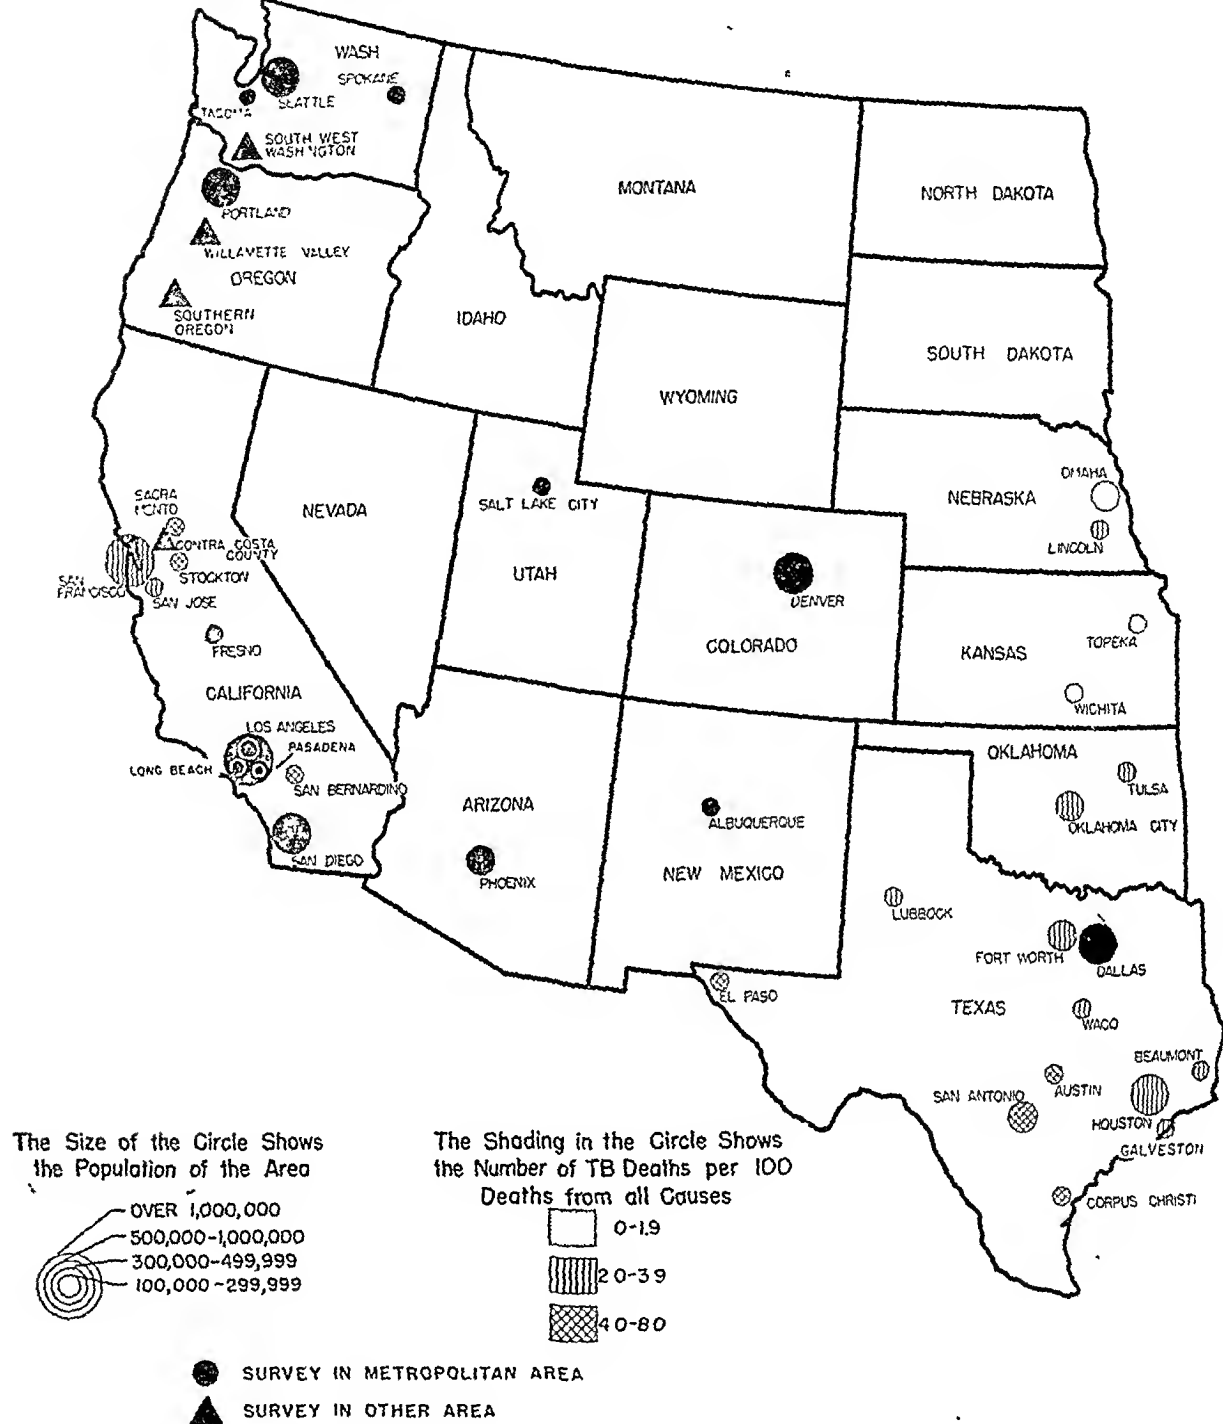

The Sanitary Landfill in Northern States

In 1948 the North Dakota State Department of Health invited the Public Health Service to participate in a study of the use of landfill techniques to provide a sanitary solution to the refuse disposal problem in cold climates. The city of Mandan, North Dakota, was selected for the study, which began in 1949.

A report of the Mandan project appeared in the March 1952 issue of *Public Health Reports*. This publication presents a more detailed and technical discussion of the experiment including the selection of the first and second sites, plans of operation, and details of construction of the landfill. An outline for a small community operation is given with information on temperature studies, physical and chemical analyses, and a tabulation of operational costs for a 1-year period.

Weaver, Leo, and Kengy, Donald M.: The Sanitary Landfill in Northern States. (Public Health Service Publication No. 226) 1952. 31 pages; illustrated, tables, charts. 20 cents.

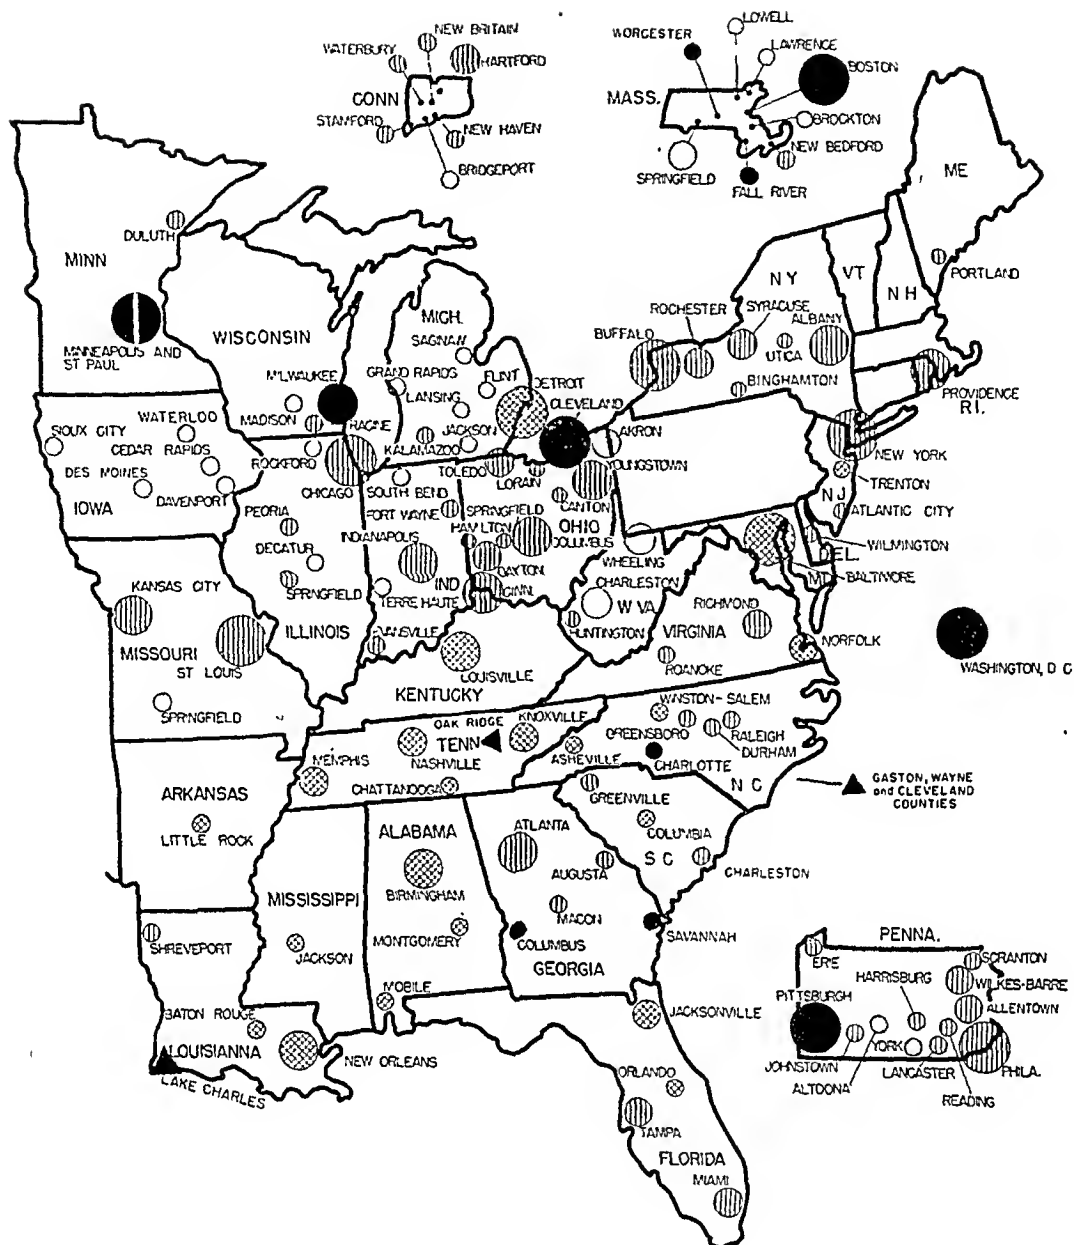

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Community-wide X-ray Surveys, 1945-1953,

Large cities in the United States have the highest tuberculosis death rates, but because of their very size they present unusual difficulties to health department case-finding activities. To help metropolitan areas carry out chest X-ray surveys quickly and effectively, the Pub-

lic Health Service, on request, provides X-ray machines and technicians. Public Health Service physicians read the films, and consultation is given by Service physicians, nurses, medical social workers, health educators, and records specialists.

conducted with Public Health Service Assistance

Since October 1945, the health officers of 31 areas have requested and received this service. These areas, 24 defined by the Bureau of the Census as "metropolitan" (over 100,000 population) and 7 other densely populated places, are indicated on the accompanying map by solid

symbols. Also shown on the map are the size and the proportionate tuberculosis mortality of the other metropolitan areas over 100,000 population. The table on the following page summarizes key findings.

Thirty-one community-wide X-ray surveys, 1945-53

¹ X-rays taken as percentage of population 15 years of age and over. ² Suspected cardiovascular findings are included in suspected other chest disease findings. The totals for each of these columns are therefore over- and under-stated, respectively. ³ Final report not yet received, survey in operation at time of publication. ⁴ In addition, over 500,000 X-rays were taken during this period in limited resurveys in Washington, D. C., and Cleveland, Ohio; in case finding surveys among migrant workers; and in other areas to which only photofluorographic equipment and technicians were supplied.

This report was prepared by the Division of Chronic Disease and Tuberculosis, Public Health Service.

Medical Education Scholarship Loans *in the* Mississippi Integrated Health Program

By FELIX J. UNDERWOOD, M.D.

THERE ARE years in the life of a State, just as in the life of an individual, that mark a kind of coming of age. Such a year in the history of Mississippi was 1946. At that time nearly half a century of work on medical, hospital, and nursing problems culminated, and new surveys, studies, and plans were made that launched the State on a new medical era.

Among the programs inaugurated in 1946 was the medical education scholarship loan program, which is helping to meet one of Mississippi's greatest medical needs—that for general practitioners in rural areas. By January 1, 1953, 120 physicians who had been granted loans under the program were in practice in the State, representing almost one-third of the total increase in physicians since 1946. An additional 15 loan recipients were in the Armed Forces, and another 52 were serving their internships.

Background of the Integrated Program

Mississippi is a rural State, with 70 percent of its people living in rural areas and securing

Dr. Underwood, executive officer of the Mississippi State Board of Health since 1924, is a member of the Mississippi State Medical Education Board. His career in public health and medicine has included the presidencies of the Southern Medical Association (1931), the State and Provincial Health Authorities (1939), and the American Public Health Association (1944).

their incomes from farm production, and, although there is some trend toward urbanization, it can be expected to be one for some time to come. In a rural State personal income can be expected to be less than that in more urban States, and the population can be expected to be scattered rather than concentrated. Thus, the large cash outlays necessary for a medical education are frequently not available from family funds, and the scattered, isolated population creates special problems in providing adequate medical care.

In 1946, Mississippi was suffering along with the rest of the Nation from 5 years of war and 10 years of depression, which had left both material and personnel problems in medical care. Few hospitals, health departments, or clinics had been built; few doctors, nurses, or other medical personnel, trained. Inquiries and surveys by the Mississippi State Board of Health and other agencies interested in the medical problems of the State, including the State medical society, the business research station at Mississippi State College, and the Farm Bureau Federation, revealed the following conditions:

Physicians. The number of physicians in the State had decreased each year since 1909, from 2,054 in that year to 1,112 in 1946, while the population of the State had increased from 1,790,000 to 2,186,000. Actually, only 915 physicians were actively practicing in 1946. The number of persons per physician had increased from 871 in 1909 to 1,966 in 1946, whereas the national average had remained around 700 dur-

ing the entire period. More than half of the physicians licensed to practice in the State were over 60 years old; only 139 were less than 40 years old.

Medical and Nursing Education. The 2-year medical school at the Mississippi State University could accept only 25 students each year; it had been compelled to reject 102 qualified applicants in the 4 preceding years. There was no college-level nursing education available for training nurses for teaching or other positions of leadership and responsibility.

Hospitals. Of the 114 hospitals in the State, only 5 were as large as 100 beds, and no general internships or residencies were available. Only 2,988 of the 4,200 beds in the general hospitals were of acceptable quality according to standards for safety, compared with a need of 7,594. The ratio of beds per thousand persons was 1.6, compared with a need of 4.5.

Health Department Facilities. There were only 12 adequate health department buildings, compared with a need for at least 70. (There are 82 counties, but several counties are in districts so that one main office serves several counties.)

Hospitalization Insurance. No statewide voluntary, nonprofit hospitalization insurance was available.

The State board of health, the State medical society, the Farm Bureau Federation, and others carried these facts to the people by personal visits and talks in almost every county. By newspaper and radio articles, by pamphlets and leaflets, the campaign went forward.

Legislative Action

These facts were also presented to the State legislature when it met in 1946, and a number of legislative committees went to work on plans to improve the situation. As a result, the legislature passed laws which (a) created the Mississippi State Medical Education Board, with sufficient funds for 2 years' operation, to grant and supervise medical scholarships; (b) created the Commission on Hospital Care to plan and direct the construction of hospitals and health centers; (c) provided for the construction of a 4-year medical school to be undertaken as soon as the rural hospital construction program

should reach a late stage of completion; (d) directed the Commission on Hospital Care to make a study of nursing needs and to plan a State program of nursing education; and (e) directed the Commission on Hospital Care to establish a statewide program of voluntary hospitalization insurance.

This was the broad outline of the integrated program to improve medical care in Mississippi. The medical education scholarship loan program, an important segment of the overall program, will be discussed in detail.

Operation of the Program

The State medical education board, which administers the scholarship loan program, is composed of five members: the dean of the University of Mississippi Medical School, the executive officer of the State board of health, the president of the State medical society, and two members appointed by the Governor for 4-year terms. It reviews applications, awards the scholarships, and approves the scholarship physician's location for practice.

A loan made through this program may not exceed \$1,250 a year for expenses, including tuition, payable direct to the medical school, or \$5,000 for 4 years. Veterans receiving aid under the GI bill of rights are eligible for loans of \$500 to \$1,000 per year payable direct to the students themselves.

To be eligible for a loan, an applicant may be either white or Negro, male or female, and must meet the following qualifications:

1. Be a resident of Mississippi.
2. Be in need of funds to complete his medical education.
3. Have completed his premedical work and be acceptable for enrollment in a class A medical school.
4. Agree to sign a contract with the State to return to Mississippi after graduation and 1-year internship (under exceptional conditions, 2-year internship may be permitted) to engage in the practice of medicine in a rural area approved by the board for a minimum of 2 years, regardless of the amount of the loan. If the scholarship physician elects to remain in the approved area for 5 years, the entire loan plus

interest is canceled at the rate of one-fifth for each year. Should he elect to repay the balance of his loan with interest at the end of 2 years, he may do so.

By the end of 1947, after the program had been in operation a year, 73 students, selected from 400 applicants, had been awarded scholarships. Applications had been received from persons in 79 of the 82 counties in Mississippi. The students were to attend 14 medical schools in the United States, including the 2-year medical school of the State university. Forty-two of these awards went to veterans of World War II; 7 went to women and 8 to Negroes.

The board's report to the legislature at the end of 1948 specified that 164 scholarships had been thus far awarded. This figure may be compared with the total of 48 awards which had been made by that time in the 8 other States having some kind of medical scholarship program in effect—Alabama, Georgia, Illinois, Indiana, Kentucky, North Carolina, South Carolina, Virginia. The Mississippi plan had produced 3 practicing physicians; the 8 other States had produced 1.

Accomplishments of the program by January 1, 1953, may be summarized as follows:

Scholarships awarded.....	406
Men, white.....	362
Men, Negro.....	30
Women, white.....	14
Medical graduates.....	195
Scholarship physicians now in practice in State.....	120
Scholarship physicians in the Armed Forces..	15
Graduates serving internships.....	52
Physicians who served minimum of 2 years and repaid loan in cash.....	5
Physicians who died before fulfilling 5-year contract.....	3
Students who failed in medical studies and repaid loan in cash.....	2
Students still in school.....	209

The 120 scholarship physicians now in practice in the State are located in 77 towns in 52 of the 82 counties. This fact gives some idea of the wide distribution of these physicians.

Problems of the Program

Most of the problems which have arisen in connection with the scholarship program have been those of routine administration common

to the handling of substantial sums of money and the selecting of the most apt and promising candidates from hundreds of applicants.

There has been some misunderstanding on the part of the students as to the objectives of the program. Some students have felt that the board should allow completion of residencies which would qualify them for practice in such specialties as surgery, gynecology, obstetrics, or eye, ear, nose, and throat. One or two medical schools have also criticized the board's policy of restricting postgraduate training to general internship. The board feels, however, that the objective of the program is to increase the supply of general practitioners, which are so badly needed in the rural areas, and not the training of specialists. The board also feels that even if a physician intends to specialize at some time in his life, it is a sound and desirable procedure for him to spend as much as 5 years in general practice prior to specialization.

Two of the scholarship recipients failed in their medical studies, but they represent such a low percentage of those receiving scholarships (0.6 percent) that this is not considered a serious problem.

The death of three of the scholarship recipients before completion of their contract to practice presents a more serious problem. Perhaps more effective health examinations for applicants should be given consideration. One of the deaths, however, occurred in a young physician who 8 months after entering practice contracted poliomyelitis of the fulminating type; no way is known to have prevented this death.

Opportunities for the Student

The scholarship program offers the opportunity for qualified persons in Mississippi who are interested in becoming rural physicians but who are unable to finance a medical education to reach their goal without incurring debts which must be repaid in cash. It should be noted that the per capita income for Mississippi is only half as large as that for the Nation as a whole, \$700 as compared with \$1,400 in 1950. The program makes it possible for the student to make a plan for his medical education and for the first 5 years of practice with reasonable

assurance that he can carry out his plan, thus relieving him of many worries and giving him freedom to concentrate on his studies.

The student under this program also has the advantage of the guidance services of the medical education board, who can offer the student much information about the professional problems of preparing for medical practice and, concerning desirable locations for practice in the State. Much of this information comes from the State medical society, the American Medical Association, the State board of health, and other agencies. The scholarship medical student is supplied with monthly reports on the general economic status of the State and of each of 14 specific subdivisions of the State. This information is furnished by the business research station of Mississippi State College, chambers of commerce, and local physicians and residents of various parts of the State.

Although a scholarship recipient is somewhat restricted as to postgraduate training and location for practice, he is free to attend any class A medical school in the United States and his first choice of location for practice is approved if it is within the provisions of the law and in keeping with the objectives of the program. Furthermore, he is not prevented from specializing nor from practicing in any location he may choose after 2 years, if he wishes to repay the balance of the loan in cash, or after 5 years, debt free.

Advantages to the State

One of the chief advantages of this program to the State is the opportunity it provides for influencing physicians to render medical service where the service is most needed. The board accomplishes this objective primarily by its approval of the scholarship physician's location for practice, but, to some extent, also by its selection of applicants. There is some advantage, for example, in securing at least a portion of the medical students from small towns and rural areas, since it has been found that physicians reared in such areas are generally better adapted to practice there.

The program also gives the State an opportunity to influence medical students to become the type of physician most needed, and gives

it some measure of control over the supply of new physicians. Since the scholarship program has provided almost one-third of the increase in number of physicians in the State since its inception, an increase or decrease in the number of scholarships awarded should have a significant effect upon the number of new physicians.

Finally, the program supplements the 4-year medical-school program, giving the school an opportunity to serve Mississippi students who otherwise would be unable to finance a medical education.

Six Years of Medical Progress

The 6 years since the integrated program for improving medical care was begun have brought progress in all the fields of endeavor. The achievements may be summarized as follows:

Physicians. The supply of physicians in the State is on the increase for the first time since 1909. The number has risen from 1,112 in 1946 to 1,500 in 1953.

Medical and Nursing Education. A 4-year medical school, which will be a part of the State university, is under construction in Jackson. It will accommodate 400 medical students and 100 nursing students. As a part of this project, a teaching hospital of 350 beds is also under construction. A nursing school of college grade has already been established at the university and is completing its fourth year of successful operation. Although it is the only school of college grade for nurses in the State, it is ample to meet all needs for this class of nurses. Upon completion of the medical school in Jackson, the nursing school will be transferred there. Three schools for practical nurses, one of which is for Negroes, have been established and are furnishing well-trained practical nurses for the first time in the State's history.

Hospitals. Thirty-eight new hospitals have been constructed and equipped and are in operation; five more are under construction. Although several hospitals have been condemned and abandoned as unsafe, the number has increased from 114 in 1946 to 141 in 1953. A total of 2,258 hospital beds have been added and 895 more are under construction. Although 195 beds were lost in abandoned hospitals, the number has risen from 4,200 in 1946 to 6,273 in 1953.

Hospitalization Insurance. A statewide program of voluntary hospitalization and surgical insurance (Blue Cross and Blue Shield) was established in 1948 and is now the fastest growing State plan in the United States. It has a membership of 250,000.

Mississippi does not claim that this progress has been made by its efforts alone. Counsel and advice have been obtained from medical leaders all over the United States. Federal funds for hospital construction, provided under the Hospital Survey and Construction (Hill-Burton) Act, have been a welcome addition to State,

local, and private funds. All the costs of the medical education scholarship loan program, the various nursing education programs, the hospital and surgical insurance program, and the 4-year medical school project, and more than one-half of all hospital and health department construction costs, however, have been paid with State, local, and private funds.

Mississippi feels that it can indeed be proud of this outburst of medical progress, for it was long in the humble position of one who recognized its needs but whose utmost efforts were unavailing to meet them.

Public Health Service Staff Announcements

Dr. Martin D. Young, scientist-director of the Public Health Service Laboratory of Tropical Diseases, Columbia, S. C., was among the first 11 persons to win a Rockefeller public service award, it was announced in February. The award was granted for outstanding research work in tropical diseases. It will enable Dr. Young to conduct further research in this field through a 9-months' inspection tour of tropical disease centers in Europe and Asia. Dr. Young joined the Public Health Service and the laboratory staff in 1937, and became director of the laboratory in 1941.

Dr. G. Milton Shy has been appointed chief of clinical research of the National Institute of Neurological Diseases and Blindness of the Public Health Service. Dr. Shy will be responsible for the planning and guidance of clinical research into the neurological and sensory disorders, among them multiple sclerosis, cerebral palsy, epilepsy, cataracts, and glaucoma. For these clinical studies, the Institute has been allocated 42 beds and 19 laboratories in the new Clinical Center at Bethesda, Md.

Prior to his appointment, Dr. Shy was chief of the neurological service at the Colorado Medical School and was a consulting neurologist at several Colorado hospitals.

Dr. Shy received his M.D. from the University of Oregon Medical School in Portland and received his special neurological training at Queen Square, London, and at

the Montreal Neurological Institute, Quebec.

Dr. James K. Shafer and Dr. Clarence A. Smith were appointed chief and assistant chief, respectively, of the Division of Venereal Disease, Public Health Service, in March 1953, by Surgeon General Leonard A. Scheele.

Dr. Shafer succeeds Dr. Theodore J. Bauer who now heads the Communicable Disease Center of the Public Health Service at Atlanta. As the new assistant chief, Dr. Smith assumes the post to which Dr. Shafer was appointed in 1950.

A veteran of 14 years' service in the commissioned officers corps of the Public Health Service, Dr. Shafer has served as venereal disease control officer in the health departments of Chicago and Moline, Ill., and Wayne County, Mich. He also served as Public Health Service consultant in the Chicago regional office.

Preceding his new appointment, Dr. Smith was venereal disease control officer for Chicago. A Public Health Service commissioned officer since 1937, he has served as medical officer in charge of the Southeastern Medical Center, Savannah, and of the Michigan Rapid Treatment Center, Ann Arbor, and has seen duty in Alabama's and South Carolina's venereal disease control programs. Dr. Smith was assistant professor of tropical medicine and public health at Tulane University School of Medicine from 1948 to 1950.

Time Between Tuberculosis Reporting And Death

By EDWARD X. MIKOL, M.D., M.P.H., and BEN Z. LOCKE, M.S.

THE REPORTING of tuberculosis cases to health departments is one of the most important administrative procedures in tuberculosis control. Such reporting identifies the person who is in need of medical and public health supervision. It results in getting him registered for such supervision and keeps him so until death, cure, transfer, or other reason for discontinuation of supervision. Each newly reported case is a new source for contact investigations leading to the possible discovery of other new cases, and reporting provides valuable statistics for the study of tuberculosis morbidity.

It has long been known that a substantial proportion of persons who die from tuberculosis have never been reported as cases before death. Each such death represents a person who either was not found as a case during life or at least failed to be reported officially as a case. Since reporting is the event which, generally speaking, puts the public health machinery into action for a given case and possible associated cases, such nonreporting signifies lack of opportunity for care and supervision by official agencies and for fulfillment of all the other purposes of reporting.

This is a report of a partial study over a period of years of tuberculosis deaths unreported as cases in New York State, exclusive of

New York City. The "unreported deaths" consist of cases reported on the same day as the date of death, cases reported after death, and deaths never reported as cases. The study was partial in that only certain information from death certificates was analyzed. A complete study would necessarily include a detailed field investigation of many factors pertaining to each unreported death, with perhaps a similar investigation, as a control, of deaths previously reported as cases.

The purpose of the study was to analyze some of the characteristics of the unreported deaths and particularly to determine, if possible, whether there might be some extenuating factors to account for the nonreporting as had been suggested by some earlier observations.

Frequency of Unreported Deaths

Table 1 shows the distribution of tuberculosis deaths according to the time of reporting as cases for two 5-year periods (annual average for 1940-44 and for 1945-49) and for 1951. The fourth column shows that slightly over 20 percent of the total deaths were never previously reported as cases before death; for example, during the period 1945-49, out of an annual average of 1,761 total tuberculosis deaths, 398 or 22.6 percent were unreported deaths.

Information is not readily available as to how this figure of a little over 20 percent for upstate New York compares with other States. (This figure should not be confused, of course, with the percentage of the total reported cases in a given year which are first "reported" by

Dr. Mikol is general director of tuberculosis hospitals in the division of tuberculosis control, New York State Department of Health, Albany, and Mr. Locke is the senior biostatistician of the division.

death certificate. In upstate New York the latter figure was 9 percent in 1940 and 5 percent in 1951.)

Table 1 shows also the number and percentage of deaths which were reported before death, divided into four "time" groups. It is encouraging that the percentage reported less than 3 months before death decreased during the period from 16.7 in 1940-44 to 10.1 (sixth column) in 1951; at the same time, the percentage reported 12 months or more before death increased from 46.0 to a peak of 56.2.

In considering the significance of the unreported deaths, the third column of table 1 shows that the number has decreased substantially from an average of 451 deaths during 1940-44 to a low of 235 in 1951. However, the percentage of unreported deaths in relation to the total deaths has shown little change since at least 1940; the annual fluctuation has been only from a high of 23.7 to a low of 20.6. This slight variance occurred during a period when there was a great expansion and improvement in case-finding techniques. It is one of the observations which has raised the question as to whether at least some of the nonreporting during life may be due to some "uncontrollable" factors.

Characteristics of Unreported Deaths

Certain characteristics of the unreported deaths for the three representative periods were analyzed.

Sex and Age

There is apparently no difference in the proportion of unreported deaths in the two sexes.

In each sex group there is a higher proportion of the unreported deaths in the age group 65 or over than would be expected by chance alone.

Place of Death

There is no difference in the proportion of unreported deaths in cities with populations of 50,000 or more as compared with the rest of the area. Table 2 shows the distribution of unreported and reported deaths in 1951 in relation to the place of death within urban and rural areas. The striking fact is that out of 194 tuberculosis deaths in general hospitals, 111, or 57 percent, were not reported before death, as compared to the 21 percent total unreported, to the 9 percent in tuberculosis hospitals (includes general hospitals with separate tuberculosis buildings or services), the 21 percent in other institutions, and the 22 percent in private dwellings. Stated another way, general hospitals contributed only 17 percent of all the deaths (194 out of 1,134), whereas they account for 47 percent of the total unreported deaths (111 out of 235).

This could mean that general hospitals are lax in reporting tuberculosis cases; perhaps this is due in some instances to failure to assign specific responsibility for official case reports. Also, it may be assumed that for the most part, patients admitted to general hospitals are more likely to have the acute types of disease, including pulmonary tuberculosis, with a diagnosis of tuberculosis being made only a short time before death.

Regardless of the explanation, this finding provides eloquent additional evidence for the

Table 1. Tuberculosis deaths in relation to time of reporting as cases, New York State, exclusive of New York City, 1940-44, 1945-49, and 1951

¹ Annual average.

Table 2. Tuberculosis deaths according to place of death and time of reporting as cases, New York State, exclusive of New York City, 1951

Place of death	Total deaths		Not reported before death		Reported before death	
	Number	Per-cent	Number	Per-cent	Number	Per-cent
Total.....	1,134	100	235	21	899	79
Tuberculosis hospitals.....	654	100	62	9	592	91
General hospitals.....	194	100	111	57	83	43
Other institutions.....	105	100	22	21	83	79
Private dwellings.....	181	100	40	22	141	78

need of extending to all general hospitals the program of routine chest X-ray examinations of all patients admitted. Also, cases of tuberculosis should be promptly reported in order that the necessary examinations of the family-household contacts may be made.

With reference to deaths in private dwellings, the percentage of unreported deaths, 22 percent, was about the same as the total of 21 percent for all places; moreover, it is significant that only 40, or 17 percent, of the total 235 unreported deaths occurred in private dwellings.

Site of Disease

Of the total 1,134 tuberculosis deaths in 1951, 44, or 4 percent, were due to tubereulosis of the meninges or to acute disseminated tubereulosis; 25 of these were unreported before death and 19 were reported. The 25 unreported deaths represent 11 percent of the total 235 unreported deaths, whereas the 19 reported are but 2 percent of the total 899 which were reported. This then is another group of deaths the nonreporting of which may be accounted for by the acuteness of disease and the usually early fatality. All 44 deaths, incidentally, occurred in either tubereulosis or general hospitals.

Performance of Autopsy

Of the total 1,134 deaths, 317 autopsies were performed: 96 of these were among the unreported and 221 among the reported deaths. The 96 unreported deaths with autopsy repre-

sent 41 percent of all 235 unreported deaths, whereas the 221 reported are only 25 percent of the total 899 reported. Unfortunately, it is impossible, without a field investigation, to determine in which instances diagnosis was not made until the autopsy was performed. But it may safely be assumed that this was so in many of these 96 unreported deaths, and this might thus be another reason for nonreporting. One can only surmise as to the number in this group in whom a diagnosis could have been made during life by means of proper and adequate diagnostic procedures.

Other Possible Factors

Deaths from tuberculosis occurring in New York State are allocated to the place of residence of the decedent, regardless of the length of such residence. Some of the unreported deaths may thus be of persons who have moved into the upstate New York area only a short time before death. Factual data on this point, however, could be secured only through a field study.

Finally, errors in the certification of the cause of death may account for some of the unreported cases.

Discussion

If it is accepted that reporting of tubereulosis cases is an essential administrative procedure in tuberculosis control, then the proportion of tubereulosis deaths not reported during life as cases becomes an important measure of some of the control activities. The observations reported here suggest that some of the nonreporting may be due to certain extenuating—or even uncontrollable—factors.

But, to the extent that such factors do play a part, at best they can account for only a portion of the unreported deaths. Nonreporting is often due to a lack of awareness of the need and purpose of reporting or a lack of a feeling of responsibility.

To be sure, the patient who is in a hospital or some other institution is at least segregated from his household associates. But one of the purposes of reporting is to assure that such associates are examined promptly. Besides, at the time of diagnosis, a fatal outcome cannot

be foretold, and reporting is thus essential for the sake of the posthospital care and supervision of the person diagnosed.

Thus, although there may be certain pathogenetic or other factors which tend to result in delayed reporting of tuberculosis cases, efforts must be intensified to improve the status of this essential activity in tuberculosis control. The health officer or other administrator responsible for tuberculosis control in a community can use each unreported death as a lead in such efforts.

Summary

Approximately 20 percent of persons dying from tuberculosis in New York State, exclusive of New York City, have not been reported as cases during life. Because of the vital place of reporting in tuberculosis control, this is a significant index in relation to the planning, conduct, and evaluation of the program.

However, certain observations suggest that nonreporting of cases before death may be due

in part to factors which are uncontrollable or, at least, difficult to control: (a) Although the number of unreported deaths has decreased substantially since 1940, the proportion of these to the total tuberculosis deaths has shown little change; (b) the proportion of unreported deaths is very high (57 percent) in general hospitals, where, on the whole, patients with acute types of tuberculosis are more likely to be admitted; (c) some of the unreported deaths are due to acute tuberculous meningitis and acute disseminated tuberculosis; (d) in some instances the diagnosis of tuberculosis is not made until autopsy; (e) some of the unreported deaths may be of persons who have only recently moved to the area; (f) erroneous certification of the cause of death may account for some unreported deaths.

But much of the delayed reporting is controllable, and efforts must be continued and intensified to secure the reporting of all tuberculosis cases promptly at the time of first diagnosis.

Reported Tuberculosis Morbidity and Mortality, 1952

Provisional reports from State health departments indicate that there were approximately 111,300 cases of tuberculosis newly reported in the United States during the calendar year 1952. Of these, about 85,000 were active and probably active cases (group "A" cases), giving an annual rate of 55 per 100,000 population.

Total new cases reported during 1952 represented a decline of about 6 percent from the number reported in 1951. A large portion of this decline is no doubt due to the new practices in reporting cases of tuberculosis and in counting them—*Public Health Reports*, 66:1291-1294 (1951).

The National Office of Vital Statistics' 10-percent sample of death certificates indicates that there were approximately 25,000 tuberculosis deaths, all forms, in 1952. This is a decline of approximately 16 percent from a similar provisional figure for 1951. Thus, the trends of the past several years are continued in 1952: a substantial decline in tuberculosis mortality but a comparatively small decline in the number of newly reported cases.

Village Polyclinics in Middle Java

By WARREN A. KETTERER, M.D., M.P.H.

THE PUBLIC HEALTH DIVISION of the Mutual Security Agency mission to Indonesia was requested in January 1952 to assign a medical officer for a 2-week period to two rural polyclinics in the Pati Peninsula on the Island of Java. The core of the peninsula is Mount Moerio, some 40 miles northeast of Semarang, and around the mountain is a fertile plain some 15 miles wide. During the war, dikes were destroyed and mosquito breeding increased greatly, causing a serious rise in the malaria incidence. This area between the mountain and the sea is densely populated.

The clinics are on opposite sides of the mountain, one in Margaredjo on the northeast side and the other in Kajuapu on the southwest side. Operated by the Mennonite Mission in Indonesia, which has had a medical relief unit in the area since 1902, the two polyclinics are located in Mennonite-owned schoolhouses. The staff, which lives at Pati, consists of a French physician, a German nurse, four Americans, including the administrator and the laboratory technician, and Javanese helpers. The latter act as interpreters, maintain records, dispense medicines, and dress wounds. No laboratory facilities are available at the Margaredjo clinic; the Kajuapu clinic has equipment for minimal laboratory procedures. The Margaredjo clinic operates 2 days a week, with

an average daily attendance of 150 patients; the Kajuapu clinic, 3 days a week, with an average daily attendance of 90 patients.

The writer's assignment to these clinics, from January 4 through 19, 1952, provided an opportunity to study the disease entities of an Indonesian rural population and to observe the problems involved in providing preventive and therapeutic services.

Analysis of Cases

A total of 1,029 patients, including 883 new patients, were seen during the 11-day visit. Sixty-one percent of the new patients were male, 39 percent female; 16.8 percent were under 9 years of age, 56.4 percent between 10 and 40 years, and 26.8 percent more than 40 years of age.

Only superficial examinations of the patients were possible because of the large number of patients and because of the language difficulty. A brief case history and a statement of the present complaint was obtained from each patient through an interpreter, translating through three languages. Consequently, minor diseases and complaints may have been overlooked if not indicated in the history. Even some major diseases may have been overlooked since many patients had more than one major disease. For example, one patient who had tuberculosis, scabies, malaria, trachoma, and tinea complained only of sudden severe diarrhea. Although laboratory facilities were minimal, laboratory confirmation was obtainable for tuberculosis, malaria, and gonorrhea.

An inventory of the major complaints of the 883 new patients (table 1) and of the major diagnoses for these patients (table 2) indicates

Dr. Ketterer, a commissioned officer of the Public Health Service, is deputy chief of the public health division of the Technical Cooperation Administration Mission (formerly the Special Technical and Economic Mission, Mutual Security Agency) to Indonesia. He has been with the mission since June 1951.

that malaria, yaws, and tropical ulcers and their accompanying symptoms are responsible for 54 percent of the illness in this population group.

Primary or secondary nutritional deficiencies were present in almost 100 percent of the patients. The complaints of aching bones and joints were attributed to secondary nutritional deficiencies resulting from diseases such as malaria and tuberculosis. The cases presented in table 2 represent those in which beriberi or other avitaminosis was the major diagnosis.

Since malaria is endemic in the area, all cases of fever and chills were diagnosed as malaria unless another diagnosis was proved. Diagnoses of malaria were frequently confirmed by microscopic examination of both thick and thin

smears. Because of the apparent high incidence of malaria in Margaredjo, 39 school children were examined for palpable spleens; of these 29, or 74 percent, had splenomegaly. Spleen index confirmation for malaria is usually reliable in Indonesia, since leishmaniasis and schistosomiasis are not prevalent.

Ulcers were the presenting complaint of the greatest number of patients. The differential diagnosis of tropical ulcer as distinguished from gummas of yaws and syphilis was difficult. Multiplicity of lesions, presence of "patek" (frambesioma), history of trauma, and presence or absence of other signs and symptoms were used for diagnosis. Many patients with tropical ulcers gave histories of abrasions from bamboo, knife wounds, chengkol (hoe)

lacerations of feet and toes, burns, shrapnel wounds, and bites from leeches and boars.

The penicillin provided by the Indonesian Ministry of Health was used sparingly and in minimal recommended doses. However, the response to penicillin therapy was unusually dramatic. Huge facial swellings from long-standing purulent otitis media and mastoiditis disappeared overnight. Three days after receiving 300,000 units of penicillin aluminum monostearate followed by warm soaks, a patient with a vast granulating infection of the entire hand and forearm returned with all but a few isolated areas healed. Several persons with double and triple infections of differing etiology responsive to penicillin were successfully treated with one injection of 300,000 units of the drug.

Yaws was prevalent, especially in the Margaredjo area, and was diagnosed on the basis of signs and symptoms in 205 of the 883 patients, although blood tests were not available. Sev-

eral cases of severe late yaws were observed in addition to the all-too-prevalent crab yaws and larger destructive gummas.

The most common eye disease found among these patients was trachoma, which was seen in all stages.

Acute venereal diseases were more prevalent in Kajnapu than in Margaredjo, a venereal disease being the major diagnosis for 11 percent and 2 percent of the patients, respectively. The proximity of Kajnapu to a military camp may explain this difference. The converse was observed in the geographic incidence of tropical ulcer and *falciparum* malaria.

Scabies, avitaminosis, and tuberculosis, diseases common to both clinics, were comparable in incidence. Cases of tuberculosis, however, were undoubtedly undertabulated because only those patients presenting obvious symptoms or whose sputum was positive on direct examination were included. Since no laboratory was available at Margaredjo, Kajnapu showed a

¹ As a single diagnosis.

much larger number of positive tuberculosis cases.

These statistics indicate the importance of regional surveys prior to undertaking preventive measures to control these diseases, particularly in a country where personnel and supplies are scarce.

Needs and Objectives

The poverty and disease existing among the population of this rich agricultural area of the Pati peninsula appear representative of much of rural Java. Despite the seeming agricultural prosperity of the peninsula, nutritional deficiencies are almost universal. Superimposed upon poverty and malnutrition are diseases induced by poor housing, lack of sanitation, overcrowding, and lack of education. Families are unable to work because of debility and sickness; thus they are caught in the vicious cycle of illness and poverty.

The need and desire for and appreciation of medical care were demonstrated by the distances the patients traveled, usually on foot, to reach the clinics; 48 percent of the 883 new patients came 4 or more miles over muddy and rough terrain. Occasionally patients travel for 8 or 10 hours by horse cart, arriving the night before they attend the clinic. Sometimes regular trips are arranged for groups who share expenses. Although no specific records of the percentage of patients making return visits to the clinic were kept, approximately half of the patients who had been requested to return did so.

For the most part, the nearly 1,000 practicing physicians in Indonesia are engaged in curative rather than preventive health activities. They object to the competition of foreign-staffed dispensaries. Therefore, increased preventive programs in public health appear to be the most practicable for reducing the suffering of the masses of the rural population.

About 90 percent of the Indonesian Ministry of Health budget of 500 million rupiah (less than \$1 per capita per year) is devoted to curative medical care and administration. Hence, technical assistance will be needed for the preventive programs. Outside assistance in the form of commodities and personnel would significantly improve, perhaps double or triple,

At the request of the Government of Indonesia, the United States, through its Technical Cooperation Administration Mission to Indonesia, is assisting the country in numerous health activities: disease control, professional education, and the rehabilitation of health centers, hospitals, clinics, and research and teaching institutions. Shown here are a maternal and child health clinic in Djakarta, Java (above) and preparations for giving injections in the treatment of yaws (below).

present preventive efforts against some of the major diseases.

The diseases which can be prevented most effectively deserve first attention. In a country having perhaps 30 million cases of malaria and 12 million cases of yaws, supplies, equipment, and technicians could bolster existing malaria and yaws campaigns by increasing area coverage and assisting in training local subprofessional personnel to carry on activities.

Tuberculosis presents one of the most difficult and threatening public health problems. Currently, there appears to be an overemphasis on leprosy—a far less menacing disease than tuberculosis—and an underemphasis on tuberculosis. A reversal of attention to these diseases would seem desirable. Practical isolation facilities and BCG inoculation might be feasible, but mass fluoroscopy and X-ray are not indicated until minimal isolation can be provided for the great numbers of persons with active tuberculosis who are now spreading the disease.

Basically, additional education facilities for the Indonesian rural population, which should provide health education as well as other types,

are essential. For those unable to obtain formal schooling, health education devices such as the nutritional posters currently used by the Ministry of Health, showing nutritious yet inexpensive foods should be expanded. Medical, nursing, and public health training for Indonesians should be accelerated through the loan of foreign professors to Indonesian institutions and through the advance training of Indonesians elsewhere.

The prevention of diseases that increase poverty and reduce the ability of labor to produce food in the fertile and densely populated Pati peninsula appears to be a necessary objective of the Indonesian Government, both from the standpoint of economic gain and from the standpoint of strengthening the Government's relations with the people. The World Health Organization, the United Nations International Children's Emergency Fund, and other international organizations as well as the Technical Cooperation Administration are rendering effective assistance to the Indonesian Government in the implementation of its program.

Veterans' Syphilis Records

Syphilis registers for veterans of the United States Army and of the United States Air Force were transferred from the dermatology and syphilology section of the Veterans Administration to the Department of the Army on April 13, 1953. The Department of Medicine and Surgery of the Veterans Administration has announced the closing of the activities of the syphilis follow-up study unit. Public health agencies need no longer return VA Forms 10-2550 to the Veterans Administration.

Health departments, clinics, physicians, and others wishing information concerning these records should direct inquiries to: Military Personnel Records Center, The Adjutant General's Office, Department of the Army, 4300 Goodfellow Boulevard, Building 203, St. Louis 20, Mo.

Inquiries concerning syphilis records for Navy and Marine Corps veterans should be directed to: Department of the Navy, Bureau of Medicine and Surgery, Physical Qualifications and Medical Records Division, Code 33, Washington 25, D. C.

Inquiries about the syphilis records of former members of the United States Coast Guard should be sent to: The Commandant, United States Coast Guard, Attention Chief Medical Officer, Washington 25, D. C.

Serology of Brucellosis in Rural Indiana

By S. R. DAMON, Ph.D., C. R. DONHAM, D.V.M., L. M. HUTCHINGS, D.V.M., Ph.D.,

B. T. SIMMS, D.V.M., and JAMES H. STEELE, D.V.M.

REGIONAL LIVESTOCK investigations in conjunction with human epidemiological studies have shown swine and cattle to be major reservoirs of brucellosis in this country. Swine have been primarily implicated in some areas and cattle in others. However, the actual prevalence of infection in the rural human population, a group with a high potential of exposure, and the extent to which it parallels the prevalence in farm animals remains more or less a matter of conjecture.

To obtain a more comprehensive concept of the human-livestock relationships, representatives of several agencies concerned with the problem of brucellosis, meeting in Indianapolis in 1946, suggested a field study of certain Indiana localities. They proposed to investigate areas representative of dairy cattle, swine breeding, and mixed types of animal husbandry by testing farm families and livestock for serologic evidence of infection. It was hoped that the extent of relative infection might then be inferred from the distribution of titers.

Dr. Damon is director of the bureau of laboratories, Indiana State Board of Health; Dr. Donham and Dr. Hutchings, professor of veterinary science and head of the department of veterinary science, Purdue University, respectively; Dr. Simms, chief of the Bureau of Animal Industry, U. S. Department of Agriculture; and Dr. Steele, veterinary director, Communicable Disease Center, Public Health Service.

The project was jointly sponsored by the Bureau of Animal Industry; the department of veterinary science, Purdue University; the Indiana State Board of Health; and the Public Health Service.

Accordingly, the township was selected as a suitable survey unit. The ideal township was considered one where the desired type of animal husbandry was practiced, a high percentage of resident families owned their farms, good lateral roads and a centrally located school or community building existed, no centers of urban population were implicated, and finally, the people were believed to be receptive to such a project. These criteria and recommendations by agencies familiar with the regional agriculture of the State guided the selection of survey areas.

During the winter months of 1946 through 1950 nine townships were surveyed. Blood samples were collected from a major portion of the farm population and livestock and were tested for *Brucella* agglutinins. The average area of the townships was 34 square miles. Surveys were conducted in the winter to avoid conflict with farm activities. Upon completion of all studies, 2,622 persons and 13,373 animals on 930 farms had been tested.

When all data were compiled, there appeared to be little correlation between the human and animal serology. The comparatively small number of human reactors were distributed far more uniformly among the nine townships than were the livestock reactors. These coexisting serologic patterns are presented and discussed in this report.

Plan of the Surveys

Organizing local citizens for the surveys proved an interesting experience in public health tactics. With the county agricultural agent as the pivot, the proposed study was first offered to members of the county medical so-

ciety, then to community leaders who could serve in an organizational capacity. Intensive publicity preceded the actual testing, which was usually completed within 1 month following formal selection of a township for survey. For the most part, local physicians collected the human blood samples, and veterinarians from the Bureau of Animal Industry, U. S. Department of Agriculture, collected the animal blood specimens (1).

Upon completion of each survey, a résumé of the serologic results was reported to the county agent's office for publication in the local newspaper. Positive results of individual human tests were forwarded to physicians designated by the participants at the time their blood specimens were drawn. Results of the animal tests were reported directly to the respective owners. When animal reactors were found on the premises, a State veterinarian or one from the Bureau of Animal Industry returned to discuss possible control methods with the owners.

It should be noted that the incorporation of educational benefits for those persons supplying the raw data and the coordination of both technical and lay facilities of many agencies were integral factors in the program's success.

Serologic Methods

Human serums. Agglutination tests were performed at the Indiana State Board of Health Laboratories. Serums were examined by employing the rapid plate method (Huddleson) as described by Hitchens (2), and a standardized *Brucella abortus* antigen. In performing the tests, serums and antigen were mixed in proportions to give results comparable to those obtained from the examination of serum dilutions of 1:40 and 1:80 by the test tube method. Strongly reacting serums were further diluted to determine titers.

Livestock serums. Specimens collected from animals were examined at the brucellosis testing service laboratory of Purdue University except for those obtained in the Elmore and Steele township surveys, which were tested in a Bureau of Animal Industry mobile laboratory unit.

Serums were examined by using the official

Bureau of Animal Industry plate agglutination technique and *Br. abortus* antigen. In this test, serum and antigen are mixed in proportions to give results comparable to those of the test tube method with serum dilutions of 1:50, 1:100, and 1:200. Examination of swine serums included the 1:25 dilution.

Results

Only individuals 10 years of age or older were examined for *Brucella* agglutinins. Of 2,622 persons, 310 (11.8 percent) came from nearby towns and the remaining 2,312 from rural areas. The former were for the most part included in the Elmore, Steele, and Winfield township surveys. The extent of serologic activity encountered in the total population tested, urban and rural, is summarized in table 1. It was rather surprising to find that only 60 persons (2.3 percent) showed any evidence of agglutinins, and of these only 3 individuals (0.1 percent) 10 years of age or older had a positive titer (4+ reading) of 1:80 or higher. Of the group of 60 persons with agglutinins, only 2 were urban residents and 2 were rural children 10-13 years of age. The remainder were all rural adults.

Of the 2,312 rural persons examined, 16.5 percent were 10-13 years of age, 43.7 percent were males 14 years or older, and 39.8 percent were females 14 years or older. With the exception of Prairie Township, it is estimated that 40-90 percent of the rural population in these age groups were tested in the individual areas. The response in Prairie Township was somewhat less satisfactory. Since the study was designed

primarily to survey the mature farm population, attention is focused upon the prevalence of reactors among the 1,930 persons 14 years and older who were living in the rural areas. The number of reacting individuals in this group is given for each township in table 2. Based on all nine township samplings, 1.8 percent of the persons tested displayed some positive titer. Among the males, 2.3 percent reacted. Of the females, 1.2 percent reacted. This difference of 1.1 percent was found to be of only slight statistical significance.

A tabulation of information obtained concurrently with the blood testing indicated more than 80 percent of the adult males, approximately 70 percent of the children 10-13 years of age, but only 54 percent of the adult females with histories of direct animal contact. All those rural persons showing a serologic titer, with four exceptions, claimed animal contact. The four exceptions, however, did drink raw milk. Information on the consumption of raw milk by persons included in the surveys was incomplete.

Prevalence in Cattle

The majority of animals tested were cattle, 7,918 altogether. At least 60-80 percent of the

adult cattle were surveyed in each township except Prairie where the percentage was somewhat less. At the time of drawing the blood samples, field crews obtained information re-

¹ At least a 4+ agglutination reading in 1:100 dilution.

garding age, sex, and prior use of *Brucella* vaccine. These data are summarized in table 3 along with the total number (543) and percentage (6.9) of reactors found.

A bovine reactor in this study is defined as one whose serum at a dilution level of 1:100 or higher completely agglutinated the standard antigen. Those animals giving a partial reaction at this level or a complete reaction only in the 1:50 dilution are designated as suspects. Data are tabulated separately for all cattle and for only unvaccinated cattle. These two analyses are included to facilitate interpretation of results and their subsequent comparison with findings reported from other areas.

In table 4 an area breakdown is given for the number and percentage of cattle reactors encountered among the total number tested, among the unvaccinated animals only, and among the unvaccinated mature females. The latter group contributed 93.7 percent of all unvaccinated cattle reactors. In addition to the positive reactors, 645 (8.1 percent) of the total cattle tested were found to be suspects. When the results from testing vaccinated ani-

mals were excluded from the data, this number was reduced to 440 (5.6 percent).

Final tabulations showed that 10 percent of the tested animals, or one-third (32.8 percent) of all reactors, had been previously vaccinated either as calves or as adults. Of the vaccinated cattle, 22.7 percent were reactors and an equal number were suspects. A certain number of the vaccinated animals which were reactors had been immunized just before the time of testing. The inclusion of results from testing the vaccinated animals increased the percentage of reactors approximately 2 percent, from 5.0 to 6.9.

Inspection of the data in table 4 indicates the variation in the percentage of cattle reactors—and probable infection—to be found in the different localities. When the data were tested for statistical significance, the percentage of reactors encountered in the dairy-cattle townships was found to be significantly different from that found in each of the other agricultural categories. Thus, brucellosis in cattle appears to be much less a problem in some areas than in others—less especially in Steele Town-

ship than in Winfield Township, which is located in the Chicago milkshed.

Prevalence in Swine

For the purpose of this study, a swine reactor is considered one whose serum agglutinated *Brucella* antigen completely in a serum dilution of 1:50 or higher. If merely a partial reaction occurred at this level or if the reaction was evident only at the 1:25 dilution level, the animal is termed a suspect.

In all 9 surveys 4,402 swine were tested, 279 males (6.3 percent) and 4,123 females (93.7 percent). Approximately 50-80 percent of the total mature swine in each area were surveyed.

Four percent of the hogs (177) were found to be reactors and 417 (9.5 percent) were suspects; 3,808 (86.5 percent) were negative. The number of reactors found in each township is given in table 5. No statistical significance was noted in the percentage differences between the sexes. As with cattle, the percentage of swine reactors in the dairy-cattle areas was found to be significantly different from that of the swine-breeding areas as well as from that of the general agricultural category.

The presentation of serologic data does not entirely dispose of the question of prevalence of

infection in this species. Control programs based on the eradication of only those animals showing a positive titer of 1:50 or higher often have failed. A certain percentage of animals manifesting lower titers will actually harbor *Brucella* and when retained may subsequently reinfect the herd, while indiscriminate disposal of all hogs reacting at this lower serum dilution level of 1:25 may result in the condemnation of many uninfected animals (3).

For these reasons, it is felt that whereas the higher titer is the more reliable index to infection in the random individual, the lower titer is more satisfactory for indicating infection in animals from herds where there are swine showing higher titers. Accordingly, the data obtained in the township surveys are further analyzed to show the number and percentage of suspects which were found on farms with swine showing higher titers (table 6). Approximately half the swine designated as suspects came from herds with swine having higher titers. When this number (200) is added to the 177 positive reactors, 377 or 8.6 percent of the total swine tested might well be considered as possibly harboring the infective organism.

Other Farm Animals

Other farm animals tested numbered 1,053: 671 sheep, 354 horses and mules, and 28 goats. None of the goats reacted. Of the sheep, 5 (0.7 percent) were positive reactors and 14 (2.1 percent) were suspicious. Of the horses and mules, 9 (2.5 percent) reacted positively, while 43 (12.1 percent) were considered suspects. The terms "reactor" and "suspect" are defined the same as previously for cattle.

Farms with Reactors

In obtaining specimens from the livestock, Bureau of Animal Industry field crews visited 930 farms. It is estimated that the livestock on approximately 75 percent of the premises in the nine areas were surveyed. One or more animal reactors were found on 260 (28.0 percent) of the farms. Nine farms (1.0 percent) harbored horse or mule reactors and 5 (0.5 percent) harbored sheep reactors. There was none with reacting goats. The township distribution of premises with cattle and swine reactors is given

in table 7. It can be seen from these figures that the exclusion of data collected from farms having vaccinated animals reduces approximately 5 percent the number of farms with cattle reactors.

The infrequent occurrence of both cattle and swine reactors on the same premises is of interest. Considering only those farms having all unvaccinated animals (849), cattle reactors were found on 135 (15.9 percent). On the other hand, reactor or suspect swine, or both, were detected on only 35 of the 135 premises, although nearly all farms having a cattle reactor also had swine tested on the premises. Actually, only 6 (0.7 percent) of the 849 farms possessed both a cattle reactor and a swine reactor. The other 29 farms had only swine suspects.

In some townships a few large, heavily stocked farms accounted for a large percentage of the reactors. These data have not been presented because total animal counts were not obtained on all farms. However, there definitely appeared to be a direct relationship between the number of animals tested on a farm and the percentage of farms with animal reactors. When results from those farms which had vaccinated cattle on their premises were excluded from the data and when the remaining farms were tabulated according to the number of animals tested on each and a grouped frequency distribution table made, it was found that the number of farms with reactors increased with the indicated increase in herd size. Only 0.3 percent of the farms having 1-5 animals tested had swine reactors and 4.8 percent had cattle reactors whereas 27.4 percent of the farms having over 25 animals tested had swine reactors and 31 percent had cattle reactors. The other step intervals showed gradations between these two extremes. These results are consistent with those of many investigators.

In table 8, the proportion of farms with reactors and the percentage of reactors found in the various species have been related with respect to the three types of agricultural areas.

Discussion

Despite the fact that percentages of cattle and swine reactors varied from one township to

another, the percentages of human reactors remained fairly constant. An inspection of the data does not indicate any direct correlation between prevalence of animal and human agglutination titers.

In attempting an explanation for these results, consideration must be given to several possibly significant factors. Serology itself is a cumulative index of past experiences which differ fundamentally in the relatively stable rural population and in the constantly changing livestock. Furthermore, titers resulting from exposure to the animals surveyed cannot be differentiated from titers resulting from contact with previously owned animals. Although there may exist a direct correlation between the incidence of new infections in human and animal populations, this study would not necessarily reveal such a relationship.

Animal contacts are largely determined by regional agricultural practices and vary from one locality to another or even from farm to farm. Virulence of *Brucella* strains are different. Consequently, a farm with many in-

fectured swine or beef cattle raised for commercial markets may not constitute the exposure provided by a single milk cow, hog, or possibly a riding horse infected with a more virulent strain of *Brucella*. It is possible that these interrelated factors may have operated to produce fairly uniform serologic patterns in man and not in the livestock.

It should be further mentioned that a sampling error in the human testing may exist. Since the blood specimens were collected at a designated testing station in each township, persons confined to their living quarters were not surveyed. This would mean that any acutely ill brucellosis cases were not tested. However, in view of the variety of diseases occurring in a population group during the winter months, it does not seem very probable that the ratio of acute brucellosis cases to the composite of other disease would have been so abnormally high as to alter the findings significantly. Inspection of the data does not indicate an unduly poor response on the part of any age or sex group to account for the small

number of positive reactors. There is a possibility, however, that the seasonal nature of the surveys did not take into consideration any peak occurrences of high titers which may have prevailed in Indiana during certain months.

Despite the many variables which enter into a study of this type, the importance of obtaining serologic patterns as an indication of the distribution and relationship of human and animal brucellosis should not be minimized. While the foregoing data are not conclusive with regard to the effect of animal brucellosis upon the spread of human infection, they are presented as evidence of the wide regional variation which may be found in the character of the animal reservoirs of brucellosis and further as an indication of serologic patterns which may possibly coexist in rural areas such as the ones surveyed.

Summary

Serologic surveys for the relative prevalence of *Brucella* agglutinins in livestock and farm families were conducted in nine rural townships representing the dairy cattle, swine breeding, and general agricultural areas of Indiana.

Less than 2 percent of 2,622 residents 14 years of age or older reacted positively to some degree. The percentage of reactors was approximately the same in each of the townships.

Of 13,373 farm animals, approximately 6 percent were found to be reactors. Of the 930 farms surveyed, 28.0 percent were found to harbor livestock reactors. Four percent of the swine population, 6.9 percent of the cattle, 2.5

percent of the horses and mules, and 0.7 percent of the sheep were reactors. Ten percent of all cattle had been previously vaccinated. When results of testing these animals were excluded from the data, 5.0 percent of the cattle were reactors. These percentages varied considerably in the different townships.

If those swine suspects found on farms having hogs with higher titers were added to the number of actual reactors, then 8.6 percent of the swine population surveyed might be considered as possibly *Brucella*-infected.

Health Services and Juvenile Delinquency

By MARTHA M. ELIOT, M.D.

In the February 1953 issue of Public Health Reports (p. 186) Dr. Martha M. Eliot states that the Children's Bureau is devoting major attention to the serious problem of getting more effective treatment for juvenile delinquents.

Her paper in this issue touches upon the close relationship between child health and child welfare, and between health services and social services. In this same issue, beginning on p. 578, Dr. George E. Gardner discusses three typical cases of juvenile delinquency referred to a psychiatric clinic by a juvenile court.

The Children's Bureau has already enlisted the interest of a wide range of juvenile experts and national and community groups in its special juvenile delinquency conferences on juvenile courts, training schools, and training of personnel to work with delinquent children.

THE MANY WAYS in which the health services have contact with children and influence their behavior need no comment, but perhaps the importance of this relationship so far as reducing juvenile delinquency is concerned does need to be explored. I believe the health services have a major role to play in efforts to solve this problem. Through the usual maternal and child health services, and in other ways, they are in a position to make a significant contribution to programs aimed at preventing juvenile delinquency; through mental health programs for children, such as child guidance clinics, they may aid materially the work of courts and institutions offering treat-

ment to children who have already become delinquent.

The necessity for such programs cannot be stressed too greatly. More than a million boys and girls were picked up by the police in 1951 because of delinquent behavior. About 350,000 youngsters were brought before juvenile courts. Between 1948 and 1951, the number of children coming before the juvenile courts that report to the Children's Bureau increased 17 percent (see fig. 1). However, the number of children in the United States in the principal age group affected (10 to 17) increased only 5 percent. During this period, then, the delinquency rate increased faster than the rate for the particular child population category.

Thus, even now hundreds of thousands of delinquent children require prompt and sound treatment if they are to be prevented from continuing in careers of delinquency and crime. Those who are coming to the attention of the police and the courts for the first time should have this treatment early. For most of these there would be more hope of satisfactory re-

Prior to her appointment as chief of the Children's Bureau in September 1951, Dr. Martha M. Eliot was assistant director-general of the World Health Organization for 2 years. As assistant chief in 1934 and associate chief in 1941, Dr. Eliot headed the Children's Bureau health and medical services.

Figure 1. Juvenile delinquency is rising. Estimated child population (10-17 years) for 1951-60 projected by the Bureau of the Census.

habilitation if prompt help were available than for those who have repeatedly been before the courts.

At the same time, preparation for an additional load of cases must be made. During the next 7 or 8 years, it is expected that there will be a tremendous increase in the age group in which most delinquent children fall, that is, the 10- to 17-year old category. The Bureau of the Census estimates that by 1960 there will be approximately 42 percent more children in this age group than there were in 1951 (see fig. 2). In other words, for every 10 boys and girls who need our attention and care now, in a few years there may be 14 or more.

We must take every precaution we can to prevent these young people from becoming delinquent, but at the same time we must realistically face the probability that some of them will get into trouble and will need proper treatment.

Focus on Local Agencies

The current program of the Children's Bureau, therefore, is to encourage communities to

do everything in their power to prevent further delinquency but not to fail to attend to the wants of those youngsters who have already become delinquent in the eyes of the law or who are on the verge of becoming so. The Bureau is recommending that communities and States strengthen certain agencies that are entrusted with the major responsibility for taking care of our young delinquents. These agencies are the police, the juvenile court, the detention home, and the training school. The Bureau is also urging that States and communities look to their administrative mechanisms that should provide focal points for coordination and integration of all the services these children need.

The experience of agencies that carry particular responsibility for treatment of delinquent children should give us sufficient warning that they need to be improved. More than one-third of the young people who come before our juvenile courts have been there previously. Even our better training schools are rarely able to claim success with more than 50 to 60 percent of the boys or girls they receive. And, of

Figure 2. The Nation now has more children than ever before—1 of every 3 persons in the United States is under 18. 1960 population estimates projected by the Bureau of the Census.

course, the most telling proof that our treatment programs for juvenile delinquents are not successful is the fact that the large majority of our present-day adult criminals started out as known juvenile delinquents.

The reasons for these failures are fairly evident. To give each delinquent young person the kind of treatment he may need is at best a difficult job. With the handicaps and lack of support they encounter, the agencies handling such youngsters for the most part can only make a rough attempt at treatment and rehabilitation.

Community Support

For example, more than half the counties in the United States offer no probation service for delinquent children. A juvenile court judge cannot do very much for a boy or girl if the court lacks a trained probation staff and competent community workers to supervise the children placed on probation and to help them adjust themselves.

In addition, each year thousands of young people are held in jail while the police or court make up their minds what to do with them. A

large number of our jails are unfit for any sort of human occupation. The Federal Bureau of Prisons has been able to authorize use for adults of less than one-fourth the more than 3,000 city and county jails it has inspected. The effect of placing a frightened, insecure, and impressionable young boy or girl in a filthy cell among the casual population of some of our jails can well be imagined. Yet it happens every day. Communities are failing to provide proper facilities for those delinquent children who require temporary detention.

A catalog of failures and reasons for failure that would stretch on to great length could be compiled. But the point has been made: If community agencies are to be counted on for offering adequate treatment to young delinquents, they must be given adequate support. These agencies don't know all the answers, but they are often successful under most difficult circumstances. Given more and better trained personnel and proper physical equipment, they can do a far better job than they are presently doing. If they were given the opportunity to study methods and results, major improvements in treatment and results might be expected.

As to prevention of future delinquency, the challenge is a tremendous one. Needless to say, it involves every agency in the community.

The best way to prevent children from becoming delinquent would seem to be to make their home and community life attractive, and socially and emotionally satisfying to them. Most of the delinquent children known to our juvenile courts are from broken and economically insecure homes. Many are members of minority races that suffer economic and social restrictions and discrimination. Yet there are many also that come from well-to-do families which have been able to offer educational and other advantages to their children which families less well off economically may lack. Lack of parental understanding, of warm parent-child relationships, or of satisfactory living arrangements or group relationships in the community often seems to be at the root of the delinquent behavior of such children. With all these contributing factors, then, and with no single factor that can be isolated as the unique cause of delinquency, it is apparent that our programs of prevention must have many facets. In these, health agencies have an important role.

Any real attempt to prevent asocial or delinquent behavior must begin early, and must be based on thorough understanding of the phases of a child's emotional and social development and the factors in family and community life that affect it. Studies of large groups of known delinquent children by Drs. Sheldon and Eleanor Glueck have shown that although the majority of these children did not become officially known as delinquents until the period of adolescence, at least half of them had histories of delinquency extending back to their eighth year or earlier.

Influence of Health Worker

In this realm of prevention, public and voluntary health services can make great contributions, particularly through child health and mental health programs. Their influence here can be exerted early and through many channels. Some contacts will be direct with families; others, indirect, through joint community activities with other agencies and individual workers.

The direct contact for public health workers ordinarily occurs in maternity clinics, child health conferences, schools, community health centers, and in similar activities. Doctors, nurses, and other health specialists see practically all children and their parents, at one time or another, in private practice or in health clinics. They see them most frequently when the children are still in their formative years. Some of these meetings are admittedly brief. There may not be time to discover deep emotional problems that might be troubling a parent or a child. The public health nurse may have more opportunity and more time to learn from the mother when she visits in the home, or from the teacher in school. But, if child health services are well conducted, time will be found to make important contributions to the emotional, as well as the physical, well-being of a child. As Dr. Benjamin Spock pointed out for the fact-finding group on health services at the Midcentury White House Conference, even in fleeting contacts, doctors, nurses, nutritionists, and other specialists have real opportunities to help make parents feel proud and confident and eager to gain understanding of their child and to help make a child feel that someone is interested in him and understands him, that here is someone to whom he can turn for help if need be.

Indirectly health experts often influence a child's growth and development through the contacts they have with persons in the community other than the parents. For adolescent children this may be even more effective than working with the child's parents or even with the child himself. Often a teacher, a recreation leader, a social worker, a church worker, a club leader may have the most influence on such a child. A health expert with knowledge and understanding of a boy's or girl's problems in growing up and with skill in handling individual situations may be able to reach far more children by working with teachers, for example, than he could by contact with individual children.

Mental Health Clinic

Among the public and private health agencies well fitted to offer this kind of educational service is the child guidance clinic or community

mental health clinic. The basic staff of this kind of clinic usually consists of a psychiatrist, a psychologist, and a psychiatric social worker. These are people who could conduct discussion groups, give lectures, write simple material for distribution. But too few of our mental health clinics actually do offer this kind of preventive service to other community agencies; too few, indeed, are equipped to handle the demands for help with delinquent children. In fact, many communities—and even some entire States—have no such clinic even for the treatment of individual children. This is a serious lack in any community, but it is particularly serious when a juvenile court judge needs the help of a psychiatric diagnosis in planning treatment for a child.

Every effort should be made to increase the number of child guidance clinics so that their facilities may be available to all juvenile courts and institutions offering treatment to delinquent children. Community health workers can be influential in getting community action of this sort.

Community health workers can help with other problems that confront workers in the juvenile delinquency field. There are the mentally defective delinquent children who may be sent to training schools for delinquent boys and girls because the schools for care of mentally defective children are not equipped to meet their needs if they commit acts contrary to law. They should not be mixed up in training schools with delinquents whose mental development is normal. So, too, epileptic children should not be committed to training schools. The problems of young unmarried mothers whose babies are born while they are in training schools also demand close attention by health workers. Health officers may have powers to condemn detention facilities, even jails, when they are unsanitary firetraps.

Improved Housing

Another possible activity of health services that relates indirectly to the prevention of juvenile delinquency is the improvement of housing. Here is a place where health, welfare, education, and housing authorities and voluntary organizations can combine their activities and

be of great influence. In many cities, the health department is in charge of housing inspection—to see that people are not living in unsafe or unsanitary quarters.

As a positive measure related to this work, some health departments and other interested groups encourage citizens to improve their own neighborhoods by their own efforts. Groups of citizens working together can go far in providing play and recreation space; cleaning up littered vacant lots; making gardens out of back-of-the-house eyesores; painting inside and out, and thereby creating new and better relations with their neighbors; and providing new opportunities for recreational activities for neighborhood groups or gangs of children. In some instances, of course, a neighborhood may be so run-down that nothing short of total reconstruction will suffice. But, however it is accomplished, a change for the good in the appearance of a neighborhood is usually a change for the good in the life of the children of that neighborhood.

Focus on Problem Families

At a recent meeting in New York of representatives of health agencies, Dr. Thomas Dublin, executive director of the National Health Council, pointed out that health problems and social adjustment problems occur quite commonly in combination. Dr. Dublin referred particularly to the findings of the St. Paul, Minn., study made in November 1948 by Community Research Associates—it is published as "Community Planning for Human Services." The study found that a group of less than 7 percent of the city's total number of families was absorbing 46 percent of the community's health services and 55 percent of the community's adjustment services offered by correctional, mental hygiene, and case-work agencies. The results of other studies lend substance to this finding.

These groups of "problem families" in our communities offer a focal point for work not only of the health agencies but also of all our social welfare, educational, and law enforcement agencies. Why these families have such knotty problems and why they continue to have them even after great amounts of money and

energy have been expended in their behalf are questions that have baffled students of our social and economic life. Contributions to our knowledge of causes of family breakdown will, we hope, bring to light factors in the causation of juvenile delinquency. Prolonged and multi-professional types of social research, both basic

and applied, must go forward to help us sort out the more significant factors from the less, and allow us to understand the influence of social and cultural as well as of economic factors that apparently play such important roles in the warping of the lives of many children and young people.

OCCUPATIONAL HEALTH

Health Hazards and Health Examinations

Are shoe-fitting fluoroscopes a health hazard? The May 1953 issue of *Occupational Health* quotes excerpts from a report on radiation exposure in New York State shoe stores. Sample findings and conclusions are: Shoe-fitting fluoroscopes were used only in stores selling children's shoes. . . . The growing child is known to be unusually susceptible to radiation effects. . . . Technical evaluation of the design, maintenance, shielding, and operation of the equipment revealed wide variations in exposure to radiation from different machines—even in machines made by a single manufacturer. . . . Education of the parent and the shoe clerk is essential. . . . The major hurdle is to keep shoe stores under proper surveillance so as to provide adequate protection for the shoe clerks and customers.

The industrial use of X-ray, fluoroscopy, and radioactive isotopes is no longer uncommon. Dr. Mitchell R. Zavon, in listing current industrial uses of radiation, suggests that the industrial physician consider the sources of hazard to which the worker may be exposed, one of which, ionizing radiation, "has become an increasing hazard not be-

cause of decreased regard for the possible danger involved but rather because of the increase in potential exposure."

The Industrial Nurse

The first nurse was employed in industry 50 years ago. Today, there are 14,000, but most have been in industry only a year. Many industrial nurses are excluded from active participation in industrial safety programs, contends Myrtle Montgomery who also asks: How can the industrial nurse recognize the medical importance of the complaints she treats when so often she is caught in the emergency demands of the first-aid room? The average industry assumes she is qualified to aid in preventing diseases and injuries, to aid in keeping employees well, and to educate them in good health, safety, and hygiene. Also, management sometimes places her in a position of unwittingly practicing medicine by expecting her to reduce medical case frequency costs in the absence of supervising physicians.

Occupational Health is issued monthly by the Division of Occupational Health, Public Health Service. \$1 a year (\$1.25 foreign mailing), 10¢ a copy, from the Superintendent of Documents, Washington 25, D. C.

Psychiatric Referrals for Delinquent Children

By GEORGE E. GARDNER, Ph.D., M.D.

THE PSYCHIATRIST feels that whenever the situation surrounding the delinquent child at the moment—his reality situation—does not account for the child's antisocial behavior, his behavior probably has roots in some internal conflict, and the child probably needs psychiatric help. If the delinquency just doesn't make sense either from the standpoint of the act itself or from the standpoint of the seeming lack of necessity on the part of the child to act in that manner, or from both standpoints, the delinquency looks suspiciously like a neurotic act.

This general definition is as significant in the great number of cases it excludes from the psychiatrist's concern as in the small number of cases it indicates need special help.

Types of Cases

On the basis of this definition, let us list a group of specific cases which are seen from time to time and on which both the psychiatrist and the juvenile court judge can agree. The list is tentative, is based on clinical observation, and does not arise from any elaborate all-inclusive theory about the fundamental nature of juvenile crime.

Dr. Gardner, director of the Judge Baker Guidance Center in Boston, presented this paper in more detail to the conference of the Surgeon General, Public Health Service, and the Chief of the Children's Bureau, with State and Territorial health officers, State mental health authorities, and representatives of the State hospital survey and construction agencies on December 9, 1952. Dr. Gardner is also editor of the American Journal of Orthopsychiatry.

The sex offender. Children brought to court for lewd practices, heterosexual, homosexual, or other abnormal sex activity have been referred to the psychiatrist ever since the latter has concerned himself with delinquent problems. The psychiatrist is occasionally confronted with cases where, because of some experience in the child's early life, other crimes, notably stealing, have become linked to the drive for sexual gratification. The only hint I know that may be of value to the judge and his associates in detecting such an emotional hookup is the senselessness of the act or suspicions about the role of the child's associates.

The runaway child who has committed no other offense. The child who runs away may be running from some intolerable home situation characterized by abuse, maltreatment, hunger, extreme deprivation. If so, the reality situation alone may account for his behavior, and no psychiatric treatment is necessary. However, the court and the psychiatrist have seen so many instances where the child has not run away in the face of the most inhuman treatment from parents, foster parents, and siblings that both the judge and the psychiatrist should be suspicious of some internal conflict when dealing with the runaway. It is my opinion that all runaways should have the benefit of at least a few interviews with the psychiatrist before we ascribe the act to the reality situation alone and thus content ourselves with merely changing the external forces surrounding the child.

Truancy unassociated with other delinquency in a child of normal intelligence. The child who has the innate ability to advance grade by grade with his fellows but refuses to attend school probably absents himself because of some

personality defect. He is unhappy and probably is so not because of some superficial difficulty with a particular teacher or classmate. He should have help to appreciate and re-evaluate his own problems.

The solitary delinquent. The child who steals or commits other offenses alone should be referred for psychiatric treatment. Because we know that children almost invariably steal with one or more children as partners, we are suspicious of the personality makeup of those few children who steal alone, and thus, we feel that at least a psychiatric investigation should be made. This refers principally to cases where the theft is committed outside the child's own home.

The child surrendered to the court for stubbornness. A child who confines his antisocial behavior, aggression, and unmanageableness to his home probably should be studied by the psychiatrist. A thorough investigation of the intrafamilial reactions as they affect him and in turn determine his behavior is needed. This presupposes a program of study and treatment that may extend to other members of the family.

The delinquent of superior intelligence. Since the formulation and widespread use of standard measures of intelligence, we no longer believe that delinquency is due solely to mental incompetency or to a moral degeneration which is attributable to lack of intellect. On the contrary, we know that most delinquents have average intelligence as measured by age level tests. Frequently, boys of definitely superior intelligence with an intelligence quotient above 115 appear before us. We feel that psychiatric investigation and treatment are indicated for all. Perhaps this is due to a persistence of the obverse of our notion that crime should not exist in the presence of superior ability, or perhaps we are moved by our feeling that here is a boy whose contribution to society may be outstanding if we can but straighten him out. Whatever may be our true motivation in these referrals, it would seem that the nonattainment of mature social standards in a boy of superior intellect is probably due to an emotional factor, preventing him from incorporating adult standards and principles. Hence, we refer him for psychiatric treatment.

Cases where the possibility of organic brain

damage, psychosis, convulsive disorder, or feeble-mindedness exists. Postencephalitic cases and children suspected of congenital or acquired syphilitic infections should be referred to the psychiatrist, who can by examination establish or rule out these conditions and outline the best medical or medico-educational program to be followed.

From observation of delinquents appearing before the court, I estimate that 5 to 7 percent of all court cases would fall into one or more of these categories. This may appear to be a very small number of delinquents referable to the psychiatric clinic, but these, except for the last group, are cases referred for psychiatric treatment, not for diagnosis only, and they do not include the cases involving stealing. The need for facilities to determine accurately which children do need treatment, including psychiatric treatment, is a serious one.

Clinical Conference

Let us hold a psychiatric clinic on three cases all charged with stealing, the most frequent delinquent offense. These cases are cited to emphasize the varying psychiatric needs of delinquent children. They demonstrate a gradient which runs from cases where the detrimental external factors almost alone can account for the delinquency to those expressions in behavior, as in the third case, that seem to have no reference whatsoever to present economic or social inadequacies. In considering these cases, we can discern the relative psychiatric treatment needs or their absence.

A CLASSICAL CASE

Frank at 13 is before the juvenile court for the eighth time, on a fourth charge of stealing. He steals money or anything convertible into money, using it to buy candy, attend movies, treat his friends. He steals alone or with others. He has already been in a correctional school for a year.

Frank lives with his mother, maternal grandmother who is blind and feeble, 5 sisters, and 3 brothers in a poorly furnished 6-room apartment in a fairly poor residential area.

The father has been before the courts 20 times in the past 20 years on charges of assault and battery, drunkenness, stealing, nonsupport, and threatening

his wife. The mother has been in court once for adultery. One older brother has been in juvenile court 14 times and twice in reform school. His charges were breaking and entering, larceny, malicious destruction of property, and truancy. Another brother has been in juvenile court twice for truancy and for larceny.

Frank's mother claims that her mother and the older daughters supervise the children in her absence, although supervision is apparently slight. The mother was separated from her husband 8 months ago. Sometimes there is not enough to eat.

Frank occasionally attends the local community house and church. He enjoys football somewhat but spends his time when at home reading comic books and crime magazines. He hangs around undesirable areas of the city.

Frank entered kindergarten at 5, repeated the first grade, and is now repeating the eighth. His marks are mainly C's and D's. He is occasionally truant or absent.

An observer at a local boys' club sees Frank as an "extremely thin, dirty, and unkempt appearing boy" but quiet, cooperative, and a good competitor, appearing to like athletics although lacking the physical qualifications for rugged, competitive work in the gymnasium.

Frank himself gives no reason for his behavior except that he gets in with the wrong boys. He adds that all boys in his neighborhood steal and that it was unfortunate he was caught. He repeatedly asserts his good intentions but finds he is unable to carry them out. He blames only himself.

Here is the classical case of delinquency arising in a home and community devoted to delinquent behavior—a broken home, poor economic conditions, mother working, little or no supervision of children, father a drunkard and criminal, mother known to the courts, and two delinquent brothers. Presumably, the role of neurotic strivings is minimized in importance by the more or less expected rational response to such admittedly adverse social and parental relationships. Obviously, only an intensive psychotherapeutic approach would reveal the primary gains so well overshadowed. The failure of repeated attempts at rehabilitation through manipulative procedures emphasizes that there are cases of stealing where the irrational, the patternized-repetitive—almost

compulsive—features are on the surface nonapparent and seem to be nonoperative as the all-important portion of the atypical behavior.

SUPERIOR INTELLIGENCE

Charles, 15, is before the court on four complaints of breaking and entering. At 10, he broke into an empty shed, but charges were never pressed, and the case was dropped.

Family history reveals that his parents had a stormy marital career. The father was convicted of a series of thefts and sentenced to prison when the boy was a baby. When Charles was 5, the father was paroled but was sentenced for 20 years after breaking the parole and is still in prison. The mother had difficulty in making ends meet, and moderate deprivations existed. She has always worked, and the boy has been supervised by relatives or friends. When Charles was 6, she divorced her husband and subsequently remarried.

Charles is now repeating the eighth grade. He repeated the seventh. This is his fourth year in junior high school. On the revised Stanford-Binet intelligence test, Charles has a mental age of 17 years, 11 months, and an IQ of 124, indicating superior intelligence.

A review of Charles' stealing episodes reveals that he acquired no money, nor did he receive any of the stolen goods which were taken by the other boys involved. He said he didn't want them. Each instance of stealing was in the company of other boys, all known to Charles to have juvenile court records. Charles never stole from home.

Charles does not want an education but wishes to work in the merchant marine because "they are a bunch of hoboes. I like them. There are no bosses. You can go anywhere you want to go when you want to go."

His only school interest is in art work. He says, "I draw cartoons." When asked for a sample sketch, he draws a cigarette-smoking, tough-looking man wearing a striped shirt with a turtle-neck collar. The man has a patched face and wears a derby hat. Charles calls him a cartoon character. He has no cartoon plot, but has many pictures and will bring them in. When we try to arrange for art classes, he says, "They probably make you draw things you don't want to." When asked if his cartoon is a sad, happy, or funny character, Charles replies, "He is a tough guy, but he is an all right one underneath." He brings in more cartoons which are pictures of

thugs and men with beaten-up faces. One scene depicts a man who has hung himself in jail, he says. Other pictures show prize fighters in various fighting positions.

His companions are inevitably those with court records. He walks 2½ miles from home to play with a boy on probation, and on the way passes many schoolmates who have never been in trouble. He has nothing against the latter but wants to play with boys who have been in trouble.

Charles wants a part-time job, not only because he feels it is a way of finally breaking away from school but also because he wants to earn money for his mother to give her some of the fun she has missed. It will also show his stepfather that he can contribute to the mother's support too.

We find a subtle combination of actual deprivations in early life and neurotic strivings expressed in stealing and allied delinquent acts. The all-consuming drive behind the boy's delinquency seems to be that he feels he must be a criminal like his father, or that he is not to succeed where his father failed. He deliberately tries to destroy himself in the community by his delinquencies, in school by an educational block, and his heart is set upon a vocation that will enable him to be a bum. His drawings bear out his ambitions and his fears in relation to this drive.

Other facts demonstrated that these self-directed tendencies toward failure and destruction were secondary to aggressive tendencies directed toward the father.

INSTINCTUAL DRIVES

Albert exemplifies the extreme end of our comparative scale of boys who steal in that the secondary material gains seem to feature little or not at all as motivating factors, and the neurotic ones seem to be all-powerful.

Albert is 16. His parents can supply the needs and luxuries of a boy of his age in his community. His father died when Albert was 5, and his mother remarried when he was 10. Albert has superior intelligence and is now in the third year in high school despite having been removed from several schools because of stealing.

When he was 8, his mother discovered clothes in his room taken from her closet. She scolded; he seemed upset; and she assumed the problem

dropped. Periodically, Albert has broken into neighborhood houses and stolen women's clothes.

On interview, Albert says, "I say I will stop, but the next day I do it. I've been taken out of schools because of it. I began stealing women's clothes when I was 6 or 7 years old. I just liked to get dressed up in this thing, and mother caught me in it, and she stopped me. I had the door locked. She took it away and hid it. Later, I found it again, dressed up in it, and she caught me again. I cried and put on my own clothes. Then it stopped for about 3 years. It started again as I finished the sixth grade. I suddenly got this urge again to wear women's clothes."

Little comment is needed to emphasize the obvious neurotic elements in this case which stands in contrast to the other 2 cases of stealing, each of the 3 taking its proper place along a scale of increasing psychiatric importance. In addition, it is easy to understand where the primary neurotic gains in such a case are uppermost—even to the seeming exclusion of secondary or material gains. In such cases manipulative procedures or changes in the environmental (economic or social) setup would have no effect whatsoever on the impulse to steal. Only insight derived from self-study under guidance offers hope for a redirection of these instinctual drives.

Psychiatric Needs

From this brief survey, we can make certain hypotheses:

1. All delinquent children need treatment of some kind whether medical, psychiatric, educational, placement, supervision—or new shoes and clothes and proper food.

2. All delinquent children do not need psychiatric treatment.

3. Although all delinquent children may not need intensive psychiatric treatment, all delinquent children need a psychiatric diagnosis first of all to determine accurately whether psychiatric treatment is needed. Psychiatric diagnosis means more than a test of intelligence and a physical examination.

Because of the shortage of trained psychiatrists and of the even more acute shortages of trained child psychiatrists the minimal diagnostic and minimal treatment needs of delin-

quent children are not being met. Needed are more psychiatric training facilities and the placement of psychiatric personnel within the court structure once they are trained.

Other needs in this area of psychiatric treatment are equally serious:

Residence centers—not detention homes—where adequate care and thorough medical, psychological, and sociological studies can be made, are needed for preliminary diagnoses of children who cannot be kept at home during their preadjudication period.

Schools and hospitals geared to long-term intensive residence treatment of delinquent

boys and girls are desperately needed. We particularly need foster home and residence treatment centers and programs for delinquent girls and for Negro children of both sexes.

Only under such conditions can we be assured that the proper medicosocial treatment programs for delinquent children will even approximate the best form of comprehensive child care.

Studies on Dental Care Services For School Children

— *First and Second Treatment Series, Richmond, Ind.* —

By GEORGE E. WATERMAN, D.D.S., and JOHN W. KNUTSON, D.D.S., Dr.P.H.

IN A COMPREHENSIVE analysis (1) of a dental survey of school children in Hagerstown, Md., Klein, Palmer, and Knutson distinguished between the accumulated and annual increment of dental needs. They concluded that the basic problem of caring for caries in the teeth of school children is that of caring for the annual increment.

The purpose of this report is to provide actual performance data on the accumulated and maintenance dental care needs of school children.

The Richmond study was a cooperative project of the Indiana State Board of Health, the city of Richmond, and the Public Health Service. Beginning December 23, 1946, it extended over a 5-year period.

The project was designed to give dental care services to all school children enrolled in kindergarten through the ninth grade, provided treatment was requested by their parents.

Dr. Waterman, assistant chief of the Division of Dental Public Health, Public Health Service, directed the dental research care program in the Richmond, Ind., schools. He is presently engaged in promoting and developing the use of auxiliary personnel in dental schools and in the dental profession.

Dr. Knutson, Assistant Surgeon General, is the chief dental officer of the Public Health Service.

Richmond was chosen for this study primarily because it provided a group of between 4,000 and 6,000 school children for a treatment and followup program, and because the project had the full approval and cooperation of the Indiana State Health Department and of dental societies and school authorities at both the State and local levels.

The city is a fairly typical midwestern community of about 40,000 people, 98 percent of whom are white and native-born. The total enrollment for all schools—kindergarten through senior high school—was 6,929 at the beginning of this study.

Situated near the eastern border of Indiana, Richmond is a railroad center and a major distribution terminal for the rich farm produce of eastern Indiana and western Ohio. It also has several small and medium-sized industries.

Clinical Facilities and Personnel

Dental clinics were set up in each of Richmond's 16 elementary and junior high schools: 14 public and 2 parochial. Wherever possible, school authorities provided attractive clinic rooms with good lighting and ventilation.

Two modern standard dental units and chairs were available to each dentist. For each 2 chairs there was 1 dental instrument cabinet containing duplicate sets of instruments. The type and arrangement of equipment, and the

provision of adequate auxiliary personnel enabled each dentist to work from a seated position at all times. These working conditions reduced the dentist's fatigue and helped to improve the quantity and quality of his services (2, 3).

The clinics varied in size from 4 chairs for schools of 300 children or less to 6 chairs for the larger schools. Two or three clinics operated at one time. As dental treatment was completed in one school, the staff dismantled equipment and packed supplies for transportation, and in less than a day later the equipment was in use again in the next school.

Personnel for the study project included between 3 and 5 dentists, a dental health educator, a secretary, and a dental hygienist to give prophylaxis and topical fluoride treatments. In addition 1 clerk was assigned to each operating clinic, and an average of 1½ dental assistants was provided each dentist.

The 5 dental assistants employed at the start of the project underwent 10 weeks of intensive training at the Naval Dental School in Bethesda, Md. They in turn helped to train assistants added to the staff later during the study.

Inservice training was provided for the entire staff once every 3 months by 1 of 7 specialists in various phases of pedodontics and in the efficient use of auxiliary personnel.

Clinical Routine

Dental record cards were prepared for the entire school population from census sheets provided by the teachers of each grade. Teachers issued "request for treatment" slips to all pupils with instructions to return them signed by a parent or guardian, indicating whether or not they wanted the child's dental care provided in the school clinics.

The dental care program was divided into four consecutive treatment series. A treatment series consisted of dental examination of the total enrollment, kindergarten through junior high school, and completed treatment of all children whose parents requested treatment.

Since the majority of dental defects in any group of children results directly from dental caries, this report is concerned principally with

caries prevalence and the treatment services required to correct carious defects.

This report is limited to the first and second treatment series.

Examination

Complete dental examinations of all children were conducted in each school. Examinations were made with a No. 4 plain mouth mirror and sharp No. 5 double-end explorers. X-rays were used whenever there was any doubt about clinical diagnosis.

The following information was recorded in examination and treatment records maintained for each child during each treatment series:

Number of primary and permanent teeth erupted and unerupted.

Number of teeth missing because of extraction.

Number of teeth missing due to other causes.

Number of roots remaining.

Number of filled and unfilled carious teeth and the surfaces involved.

Number of filled teeth and the surfaces restored.

Number of hypoplastic teeth.

Observations were made on all teeth present in the mouth. Teeth recorded as carious were those which showed actual cavities, no matter how small, as well as deep pits and fissures in which the explorer hung and penetrated with pressure.

A dental assistant recorded the information on the record cards in code to facilitate transfer to punch cards for processing and analysis. A serial number was assigned to each child for the duration of the study project. A master card index system was maintained to simplify reference to a child's previous dental record.

Treatment

Once the examinations had been completed, clinical treatment was given to all children whose parents had signed consent slips. A few days before treatment was started in a particular school, the children heard a brief talk by the dental health educator, who explained the importance of early and adequate dental care. He told why the clinic was coming to the school

and urged those receiving treatment in private dental offices to do so regularly. This introduction to the clinic program helped promote understanding and friendly cooperation among the children, the teachers, and the clinic staff. During actual treatment, the children received chair-side instruction in oral hygiene.

Clinics were operated on a year-round basis with appointments for treatment continuing during vacations and holidays. Young children were treated in the early forenoon and early afternoon, with treatment periods limited to 15 to 30 minutes. The late morning and late afternoon appointments were usually reserved for the older age groups. Their treatment periods varied from 20 minutes to 1 hour.

Extractions were generally avoided during a child's first dental experience. Efforts were made to complete all operative treatment in the teeth of at least 1 mouth quadrant during a single sitting. Fillings were polished as the sittings progressed.

The types of treatment included :

Permanent fillings (amalgam and silicate cement).

Restoration of fractured anterior teeth with full and partial crowns.

Vital partial pulpectomies of permanent and primary teeth.

Root canal therapy of permanent anterior teeth.

Treatment for periodontal diseases.

Prophylaxis.

Topical fluoride applications.

Polishing of fillings.

The amount and type of treatment given each child were noted on the record cards. Each dentist and dental hygienist recorded all of their clinical services on daily work sheets. At the end of each 10-day working period, these sheets were combined in a biweekly report showing an accurate running account of services performed during the study project.

First Treatment Series

A total of 5,523 children between 5 and 16 years of age, representing 96 percent of all Richmond children in kindergarten through the 9th grade, were given dental examinations. A total of 4,569, or 84 percent of the group, re-

quested and received dental treatment (see table 1).

Caries Prevalence

Since this report is concerned mainly with dental care service, baseline and performance data are limited to those children who took part in the clinical care program.

The average annual increment of decayed permanent teeth, estimated from the difference in prevalence rates at individual ages, was 1.1 teeth per child. The total estimated annual increment was 5,100 decayed permanent teeth.

To establish an adequate means of measuring and expressing workload for this dental care study, all teeth requiring fillings, whether or not they had previously been filled, are counted as "carious." Also counted as carious are teeth for which extraction is indicated. Approximately 75 percent of the children had 1 or more decayed permanent teeth. There was a total of 18,542 decayed teeth involving about 30,000 surfaces.

The age specific DMF (decayed, missing, and filled) rate of permanent teeth increased from 0.31 at age 5 to 11.47 at age 15 (see table 2 and figure 1). The average 15-year-old child had 9.42 decayed teeth, 1.72 missing teeth, and only 1.60 filled teeth.

More than 13 percent of the children had 1

Table 1. Age distribution of all children examined, by patient status, 1st and 2d treatment series, Richmond, Ind.

16	30	18	48	42	16	58

or more missing permanent teeth, and only 17 percent had 1 or more filled permanent teeth.

More than 34 percent of the primary teeth examined were found to be carious. The average 7-year-old had 13.58 primary teeth, of which 5.11, or more than 38 percent, were decayed (see table 3). Only 9 percent of the group had 1 or more primary teeth which had been filled prior to the first treatment series.

Treatment Provided

Since the first evidence of dental caries in permanent teeth is closely associated with the beginning of school attendance—at age 5 or 6—a school dental program of the type described here is ideal for caring for the annual increment of defects in permanent teeth. Such a program cannot, however, insure annual or maintenance care of primary teeth, inasmuch as caries usually begins to accumulate in these teeth before age 3. Therefore, during the first treatment series, when the main concern was to care for the accumulated defects of the permanent teeth, primary teeth received only emergency, or very selective, treatment.

Ninety percent of the clinical program group received complete dental care during the first treatment series; and 70 percent of the children

¹ Also included in "Carious" and "Carious and/or filled."

² Average of the rates for ages 5-16.

treated received fillings in 1 or more permanent teeth. More than 11 percent of the children had at least 1 permanent tooth extracted.

A total of 16,015 permanent teeth were filled, at an average rate of 4.20 teeth per child for all age groups. The average 15-year-old had 7.20 teeth involving 11.69 surfaces restored (see table 4).

Selective treatment of primary teeth included 2,898 primary teeth filled, and 3,341 extractions.

In addition to teeth filled and extracted, a total of 367 pulps were capped, and 151 vital

partial pulpectomies were performed on permanent and primary teeth.

Each child received at least 1 dental prophylaxis. Topical fluoride applications totaled 12,329; a serious attempt was made to provide each child with a series of 4 topical fluoride applications.

Dentist Man-Hours

There was an average of 4.3 dentists on duty during the first treatment series, or a ratio of 1 dentist to 530 children treated per year. This dentist-staffing average is based on a full 65-hour, biweekly period for all dentists assigned to the project during the first treatment series with no deductions made for administrative work, vacations, illness, training, and so forth.

Dentist man-hour rates were determined from the total clinic time actually worked by all dentists during the 24 months of the first treatment series. The number of dentist man-hours required to complete treatment of each child in the first round was 2.88. The average number of permanent and primary teeth treated per dentist man-hour was 2.17. This number included 1.50 permanent teeth filled.

Second Treatment Series

During the second treatment series, a total of 5,595 children, 93 percent of all Richmond children in kindergarten through the 9th grade, were given dental examinations. A total of 4,797, or 86 percent of the group, elected to receive treatment in the school clinics (see table 1). This number included 1,688 who had not been enrolled in school during the first treatment series, largely kindergarten and 1st grade children.

Caries Prevalence

Approximately 68 percent of the children had 1 or more decayed permanent teeth. There was a total of 12,523 decayed teeth, about 6,000 less than in the first treatment series.

The average annual increment of decayed permanent teeth during the interval between the beginning of the 2 rounds was 1.19 teeth per child.

The average number of untreated carious teeth per child at age 15 was 3.80 compared to

Figure 2. Dental caries prevalence in permanent teeth, second treatment series, Richmond Ind., ages 5-16.

9.42 in the same age group in the first treatment series (see table 2 and figure 2). The average 15-year-old now had 7.20 filled teeth whereas 24 months earlier the average had been only 1.60 for the same age group. The average DMF rates were essentially the same for all age groups in both series.

Only 167 permanent teeth were indicated for extraction in all age groups, compared to the 815 which had needed extraction during the first series. Approximately 52 percent of the children now had at least 1 filled tooth as compared with only about 16 percent at the beginning of the initial series.

There was a slight decrease in the number of carious primary teeth. The average 7-year-old had 4.75 carious primary teeth, compared to 5.11 for the same age group in the first treatment series (see table 3). This relatively slight reduction in the number of carious primary teeth can be attributed to the limited treatment provided during the first treatment series, plus the enrollment of a new crop of children in the kindergarten and first grades. During the second treatment series, however, 24 percent of the children had at least 1 filled primary tooth, compared to only 9 percent in the first round.

² Average of the rates for ages 5-16.

Treatment Provided

Complete dental care was given to 98 percent of the clinical program group with 69 percent getting at least 1 permanent tooth filled. Only 2 percent of the children required any extractions.

A total of 12,354 permanent teeth were filled, at an average rate of 2.83 teeth per child for all age groups, compared to 4.20 in the first round of treatment. The average 15-year-old had 3.47 teeth restored, compared to 7.20 for the same age group 20 months earlier (see table 4).

Since the bulk of the accumulated needs had been cared for during the first treatment series,

it now becomes possible to devote more time to treating defects in primary teeth. The number of primary teeth filled rose from 2,898 in the initial round to 5,569 in the second series.

Aside from fillings and extractions, there was no substantial change in the type or amount of other dental treatment services.

Dentist Man-Hours

There was an average of 3.9 dentists on duty during the second treatment series, or a ratio of 1 dentist to 743 children treated per year. The number of dentist man-hours required to complete treatment of each child in the second round

¹ Average of the rates for ages 5-16.

was 1.86. The average number of permanent teeth treated per dentist man-hour was about the same as in the first series. There was an increase, however, in the amount of treatment provided per dentist man-hour for primary teeth: 0.61 teeth filled as compared with 0.31. The second treatment series was completed in 20 months.

There was a reduction of 1.02 dentist man-hours in time required to complete treatment of each child. This drop may be attributed to the lower prevalence of carious teeth due to dental treatment, and improved operating and clinical procedures.

The reduction in completed dentist man-hours per child would undoubtedly have been greater except for the constant influx of children who had had little or no previous dental treatment.

Summary

An average of 4,600 school children in kindergarten through 9th grade were given dental examinations and complete dental treatment during the first 2 treatment series of the Richmond, Ind., dental care study project.

The first treatment series was designed to care for the accumulated dental needs of the group. Primary emphasis was placed on caring for defects in permanent teeth.

The second treatment series, which started 24 months after the beginning of the first, was designed to treat the increment of defects occurring during that 24-month period, and to provide more complete care for the primary dentition.

Before the first series, only 17 percent of the children had had any permanent teeth filled. This figure rose to more than 52 percent at the start of the second series.

At the beginning of the second series, it was found that the average 15-year-old had 3.80 unfilled carious teeth, compared to 9.42 in the same age group at the start of the first series.

Only 167 permanent teeth were indicated for extraction in all age groups in the second series, compared to 815 needing extraction during the first round of treatment.

The number of dentist man-hours required to complete treatment of each child in the first and second rounds was 2.88 and 1.86, respectively. This represents a reduction of 1.02 dentist man-hours, or 35 percent, for each child.

ACKNOWLEDGMENTS

The authors wish to acknowledge the assistance of the following seven specialists in various phases of pedodontics and in the efficient use of auxiliary personnel who, at quarterly intervals, provided training for the staff of the project: Kenneth A. Easlick, D. D. S., University of Michigan; Roy O. Elam, D. D. S., Nashville, Tenn.; Joseph T. Hartsook, D. D. S., University of Michigan; Ralph L. Ireland, D. D. S., University of Nebraska; Ralph E. McDonald, D. D. S., Indiana University; George C. Paffenbarger, D. D. S., Bureau of Standards, Washington, D. C.; and Helmut A. Zander, D. D. S., University of Minnesota.

They also acknowledge the assistance of the personnel of the Richmond, Ind., schools, the Richmond Dental Society, the Indiana State Board of Health, and the Indiana State Dental Society.

Adult Guidance Center, San Francisco

By McCLAIN JOHNSTON, M.D.

WITH THE RECOGNITION of chronic alcoholism as a public health problem, more interest is being shown in public education on the subject, more legislation to establish and operate clinics and hospitals for alcoholics is being passed, and medical, sociological, and psychological research in this field is increasing.

Ten months after publication of a report on the extent of alcoholism in San Francisco, the city board of supervisors made a lump sum appropriation of \$50,000 for the fiscal year 1949-50 to establish an inpatient facility for treating men charged with and convicted of drunkenness. The pilot clinic opened July 15, 1949, in the hospital ward of the men's division of the San Francisco county jail. A psychiatrist, a psychiatric social worker, and a clerk-stenographer comprised the staff. During the 20½ months the pilot clinic was in operation, medical and psychiatric treatment was given to approximately 200 patients. The pilot clinic was under the direction of the City and County of San Francisco Department of Public Health.

There were definite disadvantages in attempting to treat alcoholics in a jail setting. It was felt that the problem of alcoholism could be handled better if the treatment and punitive programs were completely separate. Funds for both inpatient and outpatient facilities were not available. However, an additional \$35,000 was added to the original budget of \$50,000 to establish and maintain a voluntary

outpatient clinic which would be apart from the jail. On April 2, 1951, the Adult Guidance Center opened and the pilot clinic in the jail closed.

Organization

The Adult Guidance Center is open 12 hours a day, 6 days a week, to accommodate patients whose work schedules might conflict with clinic attendance. A psychiatrist-director, 4 psychiatrists, 3 psychiatric social workers, 2 nurses, and 3 stenographers make up the staff. The 4 psychiatrists and 1 of the nurses are on a half-time basis. All services are free. The clinic is a bureau of the City and County of San Francisco Department of Public Health. The budget for the fiscal year 1952-53 is \$75,000.

The psychiatrists on the staff interview and evaluate new cases coming for treatment, make progress notes on the active cases who receive medical treatment only, and see cases in psychotherapy. The duties of the social workers fall into three major areas: intake-interviewing on new cases, liaison with other agencies about individual cases, and the carrying of cases in psychotherapy. The nurses administer medication, and make progress notes on cases receiving medical treatment only, when the psychiatrist on duty is interviewing a patient.

Two staff meetings are held weekly: one is for case presentation; and the other is an administrative meeting where general policy, procedural changes, and clinic problems are discussed. Each social worker has a weekly supervisory conference with the director to discuss problem cases or to review psychotherapeutic interviews.

Dr. Johnston, a psychiatrist, is the full-time director of the Adult Guidance Center, a bureau of the City and County of San Francisco Department of Public Health.

Admission

Each new patient must live in the city and county of San Francisco. He must be "dry" for 24 hours prior to admission. He must feel that he has a drinking problem. Under this criterion, we require only that the patient come to the clinic voluntarily with the realization that his drinking is causing some problem in his day-to-day living. Not all patients are chronic alcoholics in the usual sense of the expression. Many state they are not alcoholics at all. The criterion of a 24-hour "dry" period was set because the clinic is not equipped to handle the acute emergencies which severe intoxication presents. Rare cases of this type are taken to an emergency hospital. One bed is maintained in the clinic for the occasional patient with convulsions.

Patients are referred to the center from Alcoholics Anonymous and from all psychiatric clinics in the city. Referrals are also made by private physicians, the courts, municipal social agencies, the State bureau of vocational rehabilitation, the city-county hospital, and the county medical society.

Our patients represent a fair cross section of the city's population according to social and economic levels. The majority are skilled and semiskilled laborers and white-collar workers. Women have consistently represented 25 percent of the admissions since the opening day of the clinic.

Procedures and Services

On arrival, each new patient gives his name and address to the receptionist. The patient is next introduced to the psychiatric social worker. In his own way he describes his problem during an unhurried interview with the social worker—lasting from 45 minutes to an hour. Specific information for statistical evaluation is elicited at the end of the intake interview if the patient has not spontaneously provided the answers during his conversation with the social worker. Before the interview closes, the medical and psychiatric facilities available at the center are discussed with the patient. The social worker attempts to ascertain what type of treatment will be most helpful.

If a new patient manifests no interest whatsoever in group or individual psychotherapy, and if he has had no prior contact with Alcoholics Anonymous, then the functions of Alcoholics Anonymous are explained and a referral may be made to that organization.

The social worker writes a short summary of the intake interview just after seeing the patient. This summary is given immediately to the psychiatrist on duty, who reads it, and then interviews the patient. The drinking problem and the patient's general emotional status are evaluated, and again the various forms of treatment are discussed. On the first day of their contact with the clinic, most new patients are started on medical treatment which consists of adrenocortical hormones and vitamin preparations. Group and individual psychotherapy are discussed, but the first appointment with the therapist—either a psychiatrist or a social worker—is usually deferred for 2 or 3 days in most cases.

Patients are told that if they are interested in either group or individual psychotherapy they should mention their interest to the psychiatrist on duty on their return in the next few days for injections. At that time, an appointment will be made with a psychiatrist or a social worker if individual psychotherapy is requested; if group psychotherapy is desired, the patient's name is listed for one of the group meetings. When an appointment for individual psychotherapy is made with a social worker, the patient is almost always referred to the person who conducted the original intake interview.

The psychiatrist briefly checks the general physical status of the patient, and he may give him a physical examination if it seems indicated. Whenever physical disease is found or is suspected, or if a medical checkup appears necessary, the patient is referred to his family physician or to one of the city or university outpatient clinics.

The Adult Guidance Center believes that a temporary deferment in appointments is often helpful in attempting to elicit motivation for psychotherapy. Our past experience has been that many new patients, particularly patients who are weak and physically rundown from a recent "drunk" or those patients who exhibit the

usual symptoms of hangover, will request medical treatment, individual psychotherapy, and group psychotherapy. Then, in a day or two when they are closer to par, their motivation for psychotherapy would greatly decrease, and they would state that probably the hormones and vitamins would be sufficient.

On January 1, 1952, when the clinic staffing was completed, the policy that all patients be offered either individual or group psychotherapy became effective. In some cases, a patient may receive both individual and group psychotherapy. Prior to that date, only selected cases were offered psychotherapy. Although the budget appropriation provided for full staffing earlier, the acquisition of adequately trained psychiatric social workers and psychiatrists was not completed until then.

Individual psychotherapy is dynamically, that is psychoanalytically, oriented. The patient is given an opportunity to attempt to work through his emotional problems with the help of the psychiatrist or psychiatric social worker. Since all patients at the clinic have a drinking problem, with the possible exception of some of the relatives, the psychotherapy is naturally concerned with this symptom, although no specific attempt is made to limit therapy to this one aspect of psychopathology.

The clinic does extend psychiatric help to the significant member or members of the patient's family when this seems indicated.

Each one of the psychiatric social workers has had considerable experience in psychotherapy. Seldom is there a differentiation between psychiatrist and social worker as to the handling of a particular case. Individual psychotherapy is conducted by the psychiatric social worker under the supervision of the clinic director.

Group psychotherapy is also conducted along dynamic lines with the group leader, a psychiatrist, occasionally giving interpretations, focusing on a particularly significant point in the session, and at times acting as an arbiter. Generally, the group sets the pace. The leader supplies factual information when it will be helpful. The groups are small ranging from 3 to 9 persons and are separated as to sex. Each group meets once a week. The duration

of individual interviews is approximately 50 minutes. Group sessions last approximately 75 minutes.

Followup

Prior to a major policy change in August 1951, patients were given medication by injection and the frequency of patient appointments was gradually decreased. When a patient had returned physically to par and did not exhibit too much nervousness or tension, he was told that the clinic thought he was doing well and that he had probably achieved the maximum benefit from the injections. He was then asked to return in about a month for a followup interview.

On the basis of experience, this method of followup was not effective. Returns for interviews were few. With the rather sudden discontinuance of clinic contact, many patients resumed drinking. Lacking was the supporting effect of frequent interviews over a long period of time.

Patients are now seen more frequently in the early days of their treatment program, and the decreasing frequency of contact is more gradual. The philosophy of continued contact is discussed with each new patient early in his treatment, and he is told that even though he will eventually be seen only once a month, the clinic would like him to come indefinitely. Definite appointment dates are set. No patient is automatically discharged by the clinic. Patients in individual or group psychotherapy naturally attend more frequently.

In a reasonable period of time the psychiatric social worker attempts to follow by telephone any patient receiving medical treatment only who has missed an appointment. A reasonable period is determined on the basis of frequency of appointments. The tenor of the telephone contact is that the clinic has noticed the patient has missed his appointment—what can be done to help him? This procedure seldom provokes the guilt and hostility generally felt in a situation of being checked on.

It depends on the individual patient in psychotherapy whether a letter followup is used after he has missed one or more appointments. In any case the door is left open and the patient is in no way pressed to return. It is the opinion

of the staff that more active and forceful methods of followup are not directly proportional to a greater number of patients maintaining sobriety or even to longer periods of sobriety in individual cases.

Field followup has never been possible because of the small size of the social service staff. But aside from staff limitations, close followup in the home might not be desirable for the alcoholic patient. Actually, too close surveillance may operate against beneficial results.

Educational Activities

Ever since the inauguration of the clinic, staff members have given talks about the program before Alcoholics Anonymous, the Red Cross, regional groups of psychiatric social workers, and local and State public health meetings. The Adult Guidance Center has participated in panel discussions on psychiatric facilities in San Francisco during National Mental Health Week. Material concerning the clinic's functions has been sent to all social agencies, psychiatric clinics, and other referring organizations.

Research and Evaluation

To evaluate the overall results of treatment for a large group of chronic alcoholics is extremely difficult. Even sobriety, the most objective criterion, must be qualified whenever, it is discussed, since many patients who may have been sober only a few weeks or months during clinic contact have in the past been steady drinkers. With others, even though continued sobriety has not been attained, the conflict in their family relationships has decreased.

A less striking factor, but a meaningful index, is the increase in the number of days patients are spending at work because of less frequent "binges" and shorter recovery periods with clinic treatment.

A most important factor, of course, is the actual existence of a clinic to which sick patients can turn for help. This alone gives immeasurable hope and reassurance to patients and their families and friends.

Since August 1951, when the policy was initiated to have patients keep continued contact

with the clinic, the staff has been able, at any time, to enumerate the active and inactive patients.

As of February 28, 1953, 2,435 patients had been accepted for treatment, and 31,591 visits had been made to the clinic.

From August 20, 1951, through February 28, 1953, 1,573 patients sought treatment; 25 percent of these were women. The 1,573 patients were divided into 4 groups:

<i>Group</i>	<i>Percent</i>
A—Active and "dry"-----	29
B—Known to have resumed drinking-----	12
C—Patients with whom clinic has lost contact----	51
D—Discontinued clinic treatment for reasons other than drinking-----	8
Total-----	100

The clinic gives treatment to a large number of patients. At present, clinic visits average 65 a day. When the 3 criteria of clinic admission are met, treatment is begun almost immediately. No appointments need be made by telephone, and there is very little, if any, waiting for intake interviews. This immediate availability of treatment and the lenient eligibility criteria are undoubtedly important factors in the large percentage in group C. An additional factor is that this figure includes those with only 1 clinic contact. The clinic feels the 29 percent in group A is a reasonable return for the expenditure of funds and hours but naturally hopes to improve this figure. Although it is reasonable to assume that some of the patients in groups C and D are still "dry," adequate followup is not possible for several reasons: small size of the social worker staff, large number of patients, and frequent changes of address. Even though adequate personnel for followup were available, the frequent changes of address would make this activity extremely difficult.

Even the patients in group B, who are known to have had at least 1 slip, attained an average of 66 days sobriety prior to their resumption of drinking.

Since August 20, 1951, 21.1 percent of the patients have participated in either individual or group psychotherapy, or in both: 12.1 percent received at least 1 hour of individual psycho-

therapy in addition to the intake interview; 8.9 percent participated in group psychotherapy; and 0.1 percent participated concurrently in individual and group psychotherapy. The remaining 78.9 percent of the patients have received medical treatment only.

The average number of hours of psychotherapy to date is:

<i>Group</i>	<i>Average hours</i>
A-----	11½
B-----	6
C-----	6¾
D-----	6

Approximately 3 months after the clinic opened, plans were made for a controlled group study to evaluate the benefits achieved with adrenocortical hormone and vitamin therapy. Although laboratory facilities are not available for any extensive pharmacological deter-

minations, the effect of the drugs on various physical and emotional symptoms and the duration of sobriety can and are being evaluated.

The comparative effectiveness of medical treatment with or without group or individual psychotherapy is in the process of assessment, although it is often difficult, if not impossible, to state specifically the factors leading to a patient's improvement. The clinic is interested in the comparative speed of recovery from acute alcoholic symptoms with the use of adrenocortical hormones and various vitamin preparations. The results of group and individual psychotherapy can be evaluated in terms of the individual development of healthier and more adequate personality defenses leading to more mature, realistic behavior. In most cases this realistic behavior leads to the state and maintenance of sobriety.

Gamma Globulin for Poliomyelitis Is Distributed

Initial supplies of gamma globulin for use against paralytic poliomyelitis were released by the Office of Defense Mobilization and shipped to State and Territorial health officers by the Public Health Service in mid-May.

Under policies established by the Office of Defense Mobilization, about 57 percent of the total national supply of immune serum globulin available for poliomyelitis inoculations is being distributed. An additional 33 percent is for use in mass prophylaxis where epidemics are most severe. The remainder, about 10 percent, will be assigned for research and emergency purposes. Concerning the allocation plan, the Office of Defense Mobilization notes "it is expected that further modification and supplementation will be necessary from time to time in the light of experience and existing circumstances."

The first release of the agent was not sufficient to provide State health departments with their complete basic allocations. Subsequent shipments are being made automatically, without further request from health officers, until distribution of the entire basic allocation has been accomplished.

Evaluation of Sanitation Programs in a City-County Health Department

By J. A. SALVATO, Jr., M.C.E.

Objective evaluation of the environmental sanitation programs conducted by State and local health departments serves many purposes. It can provide the basis for integrating, adjusting, and balancing the programs. It can be used to demonstrate the need for obtaining and retaining competent personnel. It aids the administrator of the programs in determining whether available personnel are being utilized to do the work considered most important. It can provide facts for supporting program recommendations and policy determinations.

To be of value, evaluation studies should consider workload, work done, quality of the work, and its effectiveness. The data assembled must, of course, be reliable, and they must be interpreted in the light of thoroughness and competence of the inspections.

Continual evaluation of environmental sanitation programs has been carried on in the Erie County (N. Y.) Health Department for the past 4 years. It has proved to be effective in showing which programs need more inspection time, which are receiving too much inspection time, and which are not producing results.

Uniformity of Inspection

It must be recognized that inspections can be made with varying degrees of completeness, depending upon such factors as amount and kind

of supervision, training and experience of personnel, policies and customs of the health department, and inspection procedures. Inspection work and accomplishments can be summarized and the various environmental sanitation programs compared, however, only if all inspections are conducted with the same degree of thoroughness. Therefore, a basic requirement for evaluation studies is the establishment of uniform quality inspection based upon accepted public health principles. This necessitates the development and proper use of satisfactory compliance guides, including inspection forms or checklists, for each activity inspected and the provision of continuing in-service training for inspectors and supervisors.

The inspection-compliance forms prepared by the Michigan Department of Health in cooperation with the Kellogg Foundation; the "Recommended Guide for Satisfactory Operation of Camps" developed by the Poughkeepsie district office of the New York State Department of Health, the Public Health Service's recommended "Ordinance and Code Regulating Eating and Drinking Establishments" and its recommended "Milk Ordinance and Code," and "A Proposed Housing Ordinance," prepared by the American Public Health Association Committee on the Hygiene of Housing incorporate useful compliance guides. Manuals and guides, of course, are not a substitute for intelligent and mature judgment, but they are indispensable administrative aids which, with constant supervision, will help maintain uniform quality enforcement of a sanitary code.

Mr. Salvato is chief of the bureau of general sanitation, Erie County Health Department, Buffalo, N. Y.

Figure 1. Sample tabulations from the statistical summary form used for recording inspection data in the Erie County Health Department.

Activity	Fourth quarter	Total, 1952
1. Multiple dwellings—3 or more families:		
a. Number of places on record.....	7,083	7,083
b. Number inspected of total on record—original for year.....	319	3,180
c. Number of inspections made.....	2,284	9,391
d. Number of places with deficiencies.....	316	1,653
e. Number of places eliminating all deficiencies.....	350	1,079
2. Camps—recreational, trailer, tourist:		
a. Number of places on record.....	129	129
b. Number inspected of total on record—original for year.....	10	129
c. Number of inspections made.....	93	715
d. Number of places with deficiencies.....	19	106
e. Number of places eliminating all deficiencies.....	2	83
f. Number of permits issued.....	9	98

Workload and Work Done

In analyzing the work of a department, inspection data should be organized so that the status of every activity under supervision is readily given. For this purpose, the Erie County Health Department developed a special statistical summary form. At first completed monthly, this form is now completed quarterly. It shows not only the work accomplished during the reporting period but also a cumulative total for the year.

Two examples of the tabulations on the statistical summary form are shown in figure 1. Breakdowns similar to these may be used for all activities under routine supervision—rooming houses and hotels, nursing homes, public places, schools, swimming pools, pasteurizing plants, dairy farms, slaughter houses, restaurants, public water supplies, and so forth. A modification of these breakdowns is needed for special program activities, such as rodent control, nuisance inspections, stream pollution studies, private water supply and sewage disposal inspections, legal actions, and plan reviews.

The sum of the "Number of places on record" (fig. 1, a) for each activity is the workload of the bureau in connection with places for which it has routine responsibility. The total workload is determined by adding to this figure

the number of special program services provided.

The "Number inspected of total on record—original for year" (fig. 1, b) indicates what part of the work has been done and what part remains to be done if each place is to receive an annual inspection. This information is very valuable in planning future work. For example, the multiple dwelling tabulation shows that less than half the structures on record were inspected by the end of the year. If all structures are to be visited annually, more emphasis will have to be placed on the inspection of this activity.

The "Number of inspections made" (fig. 1, c) tells where inspection time is being spent and the average number of inspections each place has received. This information may indicate a need for redirecting inspection time or for greater field supervision. It must of course be considered in relation to the results produced. In the camp tabulation for example, all places were inspected during the year about 5½ times. This figure might be considered high, but the high percentage of places eliminating deficiencies tends to confirm that the time was well spent.

A need for redirecting inspection time, however, was found at the end of 1949 when the rec-

ord of the number of inspections made in each activity revealed that 75 percent of the general sanitation time in Buffalo was being spent investigating complaints, work which is not usually productive of lasting improvements. Inspection of multiple dwellings on a planned program basis was not possible under these circumstances. By deliberate redirection of inspection time toward multiple dwellings, it was possible over a 3-year period to inspect every multiple dwelling on a planned followup basis for the first time in the history of the city. In 1952, only about 45 percent of the housing inspector's time was spent investigating complaints, and this percentage may be reduced further when a modern minimum standards housing code recommended by the health department is adopted.

The "Number of places with deficiencies" (fig. 1, d) and the "Number of places eliminating all deficiencies" (fig. 1, e) show the progress being made and the condition of the places under supervision. If a place removes all deficiencies and on subsequent inspection is found to have slipped back, it would again be listed as a place with deficiencies. When progress is unsatisfactory, additional inspection, supervision, or review of the program may be indicated. The key may be a lack of direct supervision, poor quality of supervision, departmental policy, lack of promotional opportunities, or poor morale. Interpretation or definition of deficiencies, of course, may vary with the individual, unless adequate inservice training is given and satisfactory compliance guides are developed and used.

When places with deficiencies removed are compared with the number of inspections, an indication is obtained of the number of inspections per place corrected. The point of diminishing returns can thus be seen (fig. 2).

The "Number of permits issued" (fig. 1, f) shows those places under supervision which on inspection were found in compliance with the existing regulations, assuming that annual permits are issued only after report of satisfactory compliance is received.

Frequency of Inspection

The amount of time spent in making original inspections can be expected to vary widely from

Figure 2. Percentage of individual systems corrected and number of inspections per correction in a community sewerage survey, Erie County, N. Y., 1949-53.

the "average," dependent upon the size of the establishment, problems, missionary work done, and so forth. An original inspection requires a complete inspection report and letter confirming recommendations.

Reinspection calls for reviewing previous correspondence and corrections made, completing an inspection checklist summarizing some 25 to 50 specific items, answering identification questions, listing specific deficiencies, noting steps taken in the field to correct the deficiencies, and writing practical recommendations for correcting specific deficiencies. Major deficiencies and recommendations for corrections are confirmed in writing to the responsible person by administrative personnel. With experience and proper training the inspector can do much of the paper work, with resultant increased efficiency and accuracy of reporting.

The conditions found at the time of the last inspection should determine the time and frequency of reinspection. For some activities, an average of 3 inspections per year is needed to maintain a satisfactory operating level of sanitation. Other activities, such as rooming houses, may require only 2 inspections per year after the third or fourth year of continuous supervision, whereas private sewage

disposal systems may require 6 or 8 inspections per correction or per installation.

Inspection Supervision

Review of inspection reports by trained, experienced, and competent sanitary engineers or sanitarians directly responsible for specific activities will aid in evaluating the field work from day to day. Incomplete reports, a high percentage of "no violations," sketchy explanation of the deficiencies observed, and no recommendations, or vague and nonspecific ones, readily become apparent. An unusually large or small number of inspections made in a day may indicate whether or not an inspector is trying to do a good job.

The ratio of supervising engineers or sanitarians to inspectors will depend upon such factors as the difficulty of the work, its newness, and the degree of progress already made in obtaining satisfactory compliance. In a going housing or restaurant program, the ratio may be 1 supervisor to 6 or 8 inspectors; in a farm labor camp or recreation camp inspection program, it may be 1 to 4; a special housing appraisal or stream pollution survey may require a ratio of 1 to 2. Since environmental sanitation activities are of a wide range of difficulty, broad generalizations are usually incorrect.

Production

Information useful in the planning and management of an operating program may be obtained from the inspection data assembled on the statistical summary form, as follows:

$$\text{Average number of inspections per man-day} = \frac{\text{Number of inspections}}{\text{Number of man-days}}$$

$$\text{Average number of hours per inspection} = \frac{\text{Number of productive hours per day}}{\text{Number of inspections per man-day}}$$

The number of inspections is given on the statistical summary form. The number of man-days can be determined from payroll and attendance records; and the number of productive hours per day, by subtracting hours spent in office routine from the total working hours.

An example will illustrate the procedures for these determinations. During 1952, approxi-

mately 25,000 inspections were made in the cities of Buffalo and Lackawanna and 10,000 in the remainder of suburban and rural Erie County, not including inspections of public water supplies, sewage treatment plants, food, and food-selling places. There were 5,067 man-days on duty in the cities and 2,777 in the remainder of the county. The net average annual work year was 241 days. Analysis of a typical day showed the following "nonproductive" work: 1 hour in writing reports, discussing special problems, making appointments, receiving inservice training, and so forth; 1/2 hour in getting to the first assignment, and 1/2 hour in maintaining good public relations; therefore, of a 7-hour workday (exclusive of the lunch hour), 5 hours were spent in "productive" work. Thus:

$$\text{Average number of inspections per man-day (cities)} = \frac{25,000}{5,067} = 4.9$$

$$\text{Average number of inspections per man-day (county)} = \frac{10,000}{2,777} = 3.6$$

$$\text{Average number of hours per inspection (cities)} = \frac{5}{4.9} = 1.02$$

$$\text{Average number of hours per inspection (county)} = \frac{5}{3.6} = 1.39$$

These figures, which may be determined for a total program or for one activity, have many uses. Annual comparison of this information on an overall and activity basis will indicate trends and may show where special attention is needed. The figures also can be used to determine the approximate number of personnel needed to carry out existing inspection responsibilities or new program activities; an adjustment must be made, of course, if the activity is of more or less than "average" difficulty. For example, an analysis of a general sanitation bureau showed that it had an annual workload of 17,685 places, and that 11,271 of them were inspected during the year a total of 35,145 times. Each place was therefore inspected an average of 3.1 times. The places not inspected (17,685-11,271) amounted to 6,414. If an average of 3.1 inspections is required for reasonable control, 19,883 (6,414×3.1) additional inspections would be needed. Since this work is in the city of Buffalo, where experience has shown that 4.9 inspections can be made per man-day, 4,058 additional man-days

(19,883 ÷ 4.9) or 17 men (4,058 ÷ 241) would be needed, in addition to supplementary supervisory staff. Of the 6,414 places not inspected, however, 2,164, or one-third, represent barber and beauty shops, the inspection of which is being deemphasized. Hence the number of men needed might be reduced by one-third.

Efficiency

The inspection data may also be used in evaluating the efficiency of the sanitation bureau or of a particular program. It is first necessary to have determined by an impartial expert the amount of time that should be required to make each type of inspection. Multiplying the number of inspections actually made by the time required for each type will give the total time that should have been spent to do the work reported. The ratio of the time required to the time actually spent will give the percentage efficiency. It is not inconceivable that an efficiency of 200 or 300 percent may be found where quantity rather than quality has been emphasized.

The following calculations illustrate the procedure for determining the percentage efficiency.

The amounts of time required to make inspections in three activities, adjusted to allow for travel time, were determined separately by an impartial expert, and the total number of hours theoretically required to make the inspections reported in these activities was calculated as shown in the table. The actual time spent in making 25,000 inspections in Buffalo during 1952 was 5,067 man-days, as previously determined. Thus, the actual time spent in making the 19,640 inspections in these three activities, which represented 93 percent of the total, was 4,720 man-days. Since the number of productive hours per day was 5, the total number of hours spent in the field was 23,600 (4,720 × 5). The efficiency of the inspection work in Buffalo in 1952 was therefore 83 percent (19,640 ÷ 23,600).

In 1951, the efficiency of the inspection work in Buffalo was 76 percent; in 1950, approximately 87 percent; and in 1949, approximately 140 to 200 percent. During 1949, the first year

Theoretical time required to make inspections reported in 3 activities, Buffalo, 1952

Activity	Number of inspections made	Time required per inspection ¹		Total time required (hours)
		Minutes	Hours	
Rooming houses:				
Original inspection.....	1, 359	65	1. 08	1, 470
Reinspection.....	1, 644	50	. 83	1, 365
Multiple dwellings:				
Original inspection.....	3, 180	65	1. 08	3, 440
Reinspection.....	6, 122	50	. 83	5, 090
Complaint investigation.....	11, 021	45	. 75	8, 275
Total.....	23, 326	-----	-----	19, 640

¹ Determined by an impartial expert.

of actual operation of the city-county health department, inspections were not based upon any uniform inspection report form or checklist. During 1950 and 1951, reorganization, inservice-training, full-time operation of the Public Health Service-New York State-Erie County sanitary inspectors training school and the development of uniform inspectional procedures received first priority. These efficiency figures show the changing emphasis from quantity to quality inspection. Such figures must, of course, be interpreted with caution, as figures in themselves may be valueless.

Summary

The development of satisfactory compliance guides and inspection report forms and the provision of inservice training and adequate, competent program supervision are essential for inspection data to be significant. Environmental sanitation programs and activities in different health departments can be compared only if the quality of the work, accomplishments, and supervision are on the same level. Analyses mentioned here are subject to different interpretations dependent upon local conditions. The evaluations are valuable administrative guides which, when properly used, will serve the administrator well.

The National Conference On World Health

A selective report of discussions in Washington, April 6-8, 1953, sponsored by the
National Citizens Committee for the World Health Organization

FROM April 6 through 8, 1953, a National Conference on World Health met in Washington. Its participants primarily were representatives of civic and professional organizations—more than 100 groups sent accredited delegates—called together by the National Citizens Committee for the World Health Organization.

The chairman of the committee's steering group—Frank G. Boudreau, M.D., of the Milbank Memorial Fund—remarked at the conference that "doctors and other public health workers know that health is not something you can hand over to people, like food or money. Health—personal, national, or international—must be worked for, it must be wooed and won. Therefore, it stands to reason that health above all other subjects, needs the understanding and support of the peoples of every country."

It was this line of thought, Dr. Boudreau noted, that prompted WHO to suggest organizing national citizens committees for the World Health Organization. Similar committees now exist in Austria, Canada, and Finland. The United States group grew out of separate explorations by the National Health Council and the American Association for the United Nations. The steering committee,

nucleus of the present National Citizens Committee for the World Health Organization, was authorized by the National Health Council in January of 1951. Now an independent organization, the National Citizens Committee states its purpose is "to acquaint our people with the relationship of public health to the general welfare and peace in all parts of the world community, and to increase appreciation of the importance of international health programs."

The chief responsibility of the Washington conference of April 1953, Dr. Boudreau said, is "to help the steering committee work out the role which the National Citizens Committee should play, and to make recommendations concerning its methods, program content, and the channels through which it should operate."

The real labor of the conference took place in 6 working parties or seminar groups, supplemented by reports and observations by leaders in international health affairs. In advance of publication of full proceedings by the National Citizens Committee, Public Health Reports presents a report of the operations of the World Health Organization, illustrations of WHO/UNICEF cooperative projects, and short quotations from three talks.

The Nature of the World Health Organization

By HENRY VAN ZILE HYDE, M.D.

ON AUGUST 18, 1796, Harman Blennerhassett, writing from New Utrecht, Long Island, New York, to a friend in England, told the following tale:

"Some time last summer, a Yankee, at a little town in the State of Massachusetts, learning the times were mortally sickly at Port au Prince, conceived a scheme of sending there a cargo of—coffins. Those commodities were made up in nests of sizes, from the largest to those for infants and, that no room should be lost, the inner coffins of the nest were packed with cakes of—gingerbread. I have only to add, that the speculation turned out a capital hit—our Yankee having actually returned full freighted with the best West Indies produce, in return for his timber."

On March 17, 1953, 157 years later, a dispatch originating in Port au Prince appeared in the New York Times under the headline: "U. N. and U. S. Help Haiti Fight Yaws—Antibiotic Injections Rapidly Wiping Out Disease Once Infecting 1,000,000."

This dispatch tells the dramatic story of an international cooperative effort to eradicate a disease which is holding back the growth and development of a neighboring nation. It tells of cooperation which involves a number of agen-

cies and governments—cooperation carried on under the inspired and inspiring leadership of the World Health Organization.

Between Blennerhassett's letter of 1796 and the New York Times story of 1953 lies not only the discovery of the causes of infectious disease and their methods of control but also an awakening to the fact that prosperity for all lies in health rather than in disease: in life, rather than in death.

Today, the world reaches out with a helping hand, not with coffins but with trained personnel and with scientific, practical knowledge and skills for the promotion of human health. This is the great purpose of the World Health Organization.

Organization of WHO

The organizational structure of the WHO follows, in general, the simple pattern characteristic of the other specialized agencies.

A World Health Assembly composed of representatives of all the member states meets annually as the governing body of the World Health Organization. It determines the policies, votes the budget, and assesses the members.

An executive board composed of 18 technically qualified persons designated by 18 governments chosen by the Assembly meets twice annually to review the Director-General's budget proposals and to delve into the many matters of policy, administration, and relationships referred to it by the Assembly.

A secretariat, appointed and lead by the Director-General, carries on the day-to-day work of the Organization.

A feature unique in the United Nations structure is the regional organization of WHO.

Dr. Hyde, now chief of the Public Health Service's Division of International Health, formerly was head of the health staffs of the Technical Cooperation Administration and the Institute of Inter-American Affairs. He has served since 1948 as the United States member of the WHO executive board.

"Learning and knowledge are to be gained from our mistakes as well as from our victories. It is to be hoped that from the work that is being done throughout the world in international health it may be possible for some of the less developed countries to avoid some of the mistakes of the more developed countries. Some short cuts may be made, and a great deal of grief can be avoided by learning from mistakes.

"It is important that we all recognize that no group, no culture, no people, has yet found the perfect way of living—not even of providing medical care. There is something to learn from all patterns and there is something to be discarded from all patterns about which we know anything at the present time. There is much to be learned from the attitudes of the so-called underdeveloped countries. Many of them have developed wisdoms that we have hardly ever had or have forgotten. I think no person has worked in international health—and particularly those who have worked in close contact with the people of the underdeveloped countries—who has not gained greatly in terms of his own experience and stature and value of his own community. . . .

"The people of the underdeveloped countries are

very tolerant people, generally. They are willing to absorb the peculiarities of those who come to help them, and some of our customs are very peculiar indeed, from their points of view. It is so easy for us to take for granted that our ways are or should be standard and that if everyone would just do things the way we do them everybody would live happily ever after; there would be no conflicts and everything would be fine. Of course, this is not true. In our own groups and in our own cultures, we also have troubles. We have not yet found all the answers and it would be a very bold person indeed who would go into any underdeveloped country and say: 'You should do as we do and then you will have no more troubles.' Yet occasionally this is the attitude that is taken towards some of the underdeveloped countries. When that does happen the people of those countries are very polite. In effect they say, 'Oh yeah,' and let it go at that. They are far more polite, generally, than we are. They are far more willing to accept our peculiarities than we to accept theirs, and they even try to understand our limitations and make allowances for us."

—Brock Chisholm, M. D.

Director-General, WHO, 1948-53

The World Health Assembly has divided the world into six regions in order to decentralize operations and, to a degree, policy development. In each of these regions there is a regional office and a regional committee. The regional office is headed by a director, appointed by the executive board on the nomination of the regional committee. The regional director reports to the Director-General. The regional committee is composed of the governments of the region. It meets annually to review regional problems and needs and proposed plans and budgets. Program development and budget construction begin at the regional level and finally take form in the Assembly.

Through its decentralization, WHO is brought nearer to the people and to the governments it serves, being more responsive to their needs.

Functions

The World Health Organization exists in order to render service, first, to the world at large and, second, to its individual members—the governments of which it is composed.

Services to the World

There are certain services that must be performed on a world basis if they are to have significance. These services are not new with the World Health Organization. They have grown up during the past half century as the world has become an increasingly more intimate place. They had their origins in the International Office of Public Health, which was founded in 1907, in the Pan American Sanitary Bureau, and in the League of Nations.

Daily from Singapore, throughout the vast reaches of the Pacific, and from Geneva, and over a network reaching Africa, Europe, and the Americas—WHO broadcasts reports on pestilential disease as a guide to shipping and an aid to quarantine officials. In the East, where cholera, plague and smallpox remain a daily concern, this is a service of first importance. We can hope to see an end of this business in our time. But it is not yet. Unnecessary diseases, including the easily preventable scourges of the Dark Ages, are still the daily companions of vast numbers of our fellow men. That fact must weigh heavily on our own consciences, so long as it remains a fact. Meanwhile, WHO must perform those services which limit such diseases and keep them within bounds.

Certain agents important in medicine and public health are used universally. These include antitoxins, serums, vaccines, antibiotics, vitamins, and insecticides. World War I showed the need for the development of international standards in regard to such products. While tetanus antitoxin manufactured in the United States and that manufactured in France were equally effective, they were differently measured and marked because there was no internationally agreed unit of measurement. As a result, soldiers died horribly and unnecessarily, because of errors in dosage. Today within WHO the world has a system of standardization, serving all people everywhere. In the research laboratory in Bethesda, Md., at the bedside in Rangoon, in the jungle field station on the Congo—scientists, medical officers, and native vaccinators speak the same language. In utilizing WHO standards, they understand one another, immediately and distinctly.

WHO serves as the world clearinghouse in the many fields of knowledge which, taken together, constitute "public health." Through panels of experts drawn from the world at large, it keeps itself abreast of knowledge. On occasion, committees of experts, drawn from these panels are brought together to resolve special problems or advise on current issues. Reports of these committees are basic documents in health throughout the world. There are some 50 such reports now dealing with the control of particular diseases such as tuberculosis, schistosomiasis, and malaria; with training and administration;

with broad problems such as environmental sanitation and nursing. The world looks to WHO to keep it reliably informed and up to date.

Services to Members

A new thing in our generation—an area of great hope and promise—is the service that WHO is rendering to its members in the management of their own health problems and in the development of their own health services. It is here that we can see a new future for the billions of mankind. We see, in the distance, man living as man should—clean, healthy, and productive; free and at peace.

There are three elements to this aspect of the WHO work—advice, demonstration, and training.

1. *Advice.* The WHO is prepared to send advisers on any phase of public health to governments seeking such assistance. Such advisory service may relate to the organization and administration of public health on a national basis. An international team sent to Israel, for instance, reviewed the national health service at the request of the Government and made important, far-reaching recommendations. Advisory services may also be highly specialized, as when advisers are sent to Chile in connection with the production of diphtheria and whooping-cough vaccine to be used in a nationwide campaign. Advisers are drawn from the permanent central or regional secretariats or, perhaps more often, on a short-term basis from national and local health services, public and private laboratories, universities and foundations in all parts of the world.

2. *Demonstration.* Carrying advice into the field of practical action, WHO, on the request of governments, conducts demonstrations of modern public health methods. Four WHO demonstrations of malaria control, conducted in widely separated parts of India, created the understanding and popular demand that has led to a nationwide project now being launched with a view to the mass control of malaria in India during the next 3 to 5 years.

In India today there are an estimated 100 million cases of malaria each year. Its control would release some 3 billion man-days of pro-

ductive effort and lift an incalculable burden of human suffering. Last spring I visited the Terai, the great plains at the base of the Himalayas. I was shown a modern 16,000-acre farm which 2 years previously had been a tiger forest. Only through malaria control had it been possible to open up this fertile area which had been unproductive through the centuries. This was an example of what can be done and is being done in many areas of the world. A WHO demonstration team was at work in the Terai and can be credited with giving new life to an area of great potential.

It has been my privilege to visit many countries in which WHO is at work. I have seen its malaria demonstration teams in the foothills of the Himalayas; its tuberculosis teams in Delhi, Karachi, Baghdad, and El Salvador; its maternal and child health teams in Columbia, Egypt, and Najafghar, India. Even a cursory glance through the Director-General's annual report gives a sense of great accomplishment over wide areas of the world. Vital and vigorous projects are under way. It is, indeed, heartening to find the influence of the World Health Organization reaching so deeply into the far parts of the earth. Demonstration teams are planting seeds of knowledge that are growing among the peoples of the world, that are seen and understood in their deep significance by the governments.

3. *Training.* While demonstrating ways and means of attaining progress in health, WHO is assisting in building up a corps of trained men and women, everywhere, to do the job that must be done. During its short career, WHO has awarded 2,608 fellowships for foreign study to physicians, nurses, sanitary engineers, and other technicians. This group, with the thousands trained under the auspices of private foundations and various government programs, are the world health leaders of the future.

To a large extent, WHO owes its own existence to the leadership of men and women who, a generation ago, had similar opportunities for foreign study under the Rockefeller Foundation program.

The WHO training program is not limited to fellowships alone. Teaching missions, regional seminars, visiting lecturers, and other

"I am told and I have observed personally in many countries, that mothers and fathers in the less developed countries love their children dearly. These people dislike illness and suffer pain as much as we do. In the Near and Far East you will see many blind and near blind people on the streets; people with sore eyes, living skeletons engaged in hard work, many, many hopeless cripples. So the survivors of the perils of infancy look forward to lives of sickness and pain, brought to a premature close long before they have lived out the normal span of life. . . . We must face the question as to whether in similar circumstances, we would not be apt to embrace any doctrine no matter how evil, if it gave us hope of relief from sickness, pain, and premature death. One thing we can do, and the quicker we do it the better, is to help the people of the less fortunate countries to clear away the mass diseases, for there can be no economic development, no rise in the standard of living, until this barrier has been removed. We must then go on to help them to develop their material and human resources, and in both of these things the World Health Organization is best fitted of all UN agencies to lead the way."

—Frank G. Boudreau, M.D.

available devices are utilized to build the strength of teaching institutions around the world.

Coordination

The World Health Organization is not working alone. Rather, it is the coordinating force in a complicated structure of many agencies. Under its constitution it is the "coordinating and directing authority in international health work."

There are a number of agencies concerned with various aspects of world health: United Nations International Children's Emergency Fund; United Nations Educational, Scientific, and Cultural Organization (UNESCO); the Food and Agricultural Organization (FAO); the Technical Cooperation Administration (TCA); the Mutual Security Administration (MSA); the Colombo Plan; private agencies

and foundations, industry, churches, and others. Each has its special motivation, its special drives, its own resources, its special values.

It is not strange that the world should be a complicated environment. Certainly a local community is a complicated affair with its several departments of local government, its PTA's, Rotary Club, women's clubs, church groups, chamber of commerce ad infinitum. A concept that the world should be simpler than the town is not a valid one. The job of the World Health Organization is not, as some have proposed, to stand alone and do the whole job of international health. Rather, its job is to mobilize the great forces that are available; to give the lead to us all.

It is doing this. It is increasingly setting the sights for all agencies, pointing up opportunities for social and economic advancement through health improvement. It has brought about jointness of operation in the place of what could have been duplication and waste. Examples of its coordinating activity are found in joint committees with FAO, ILO (International Labor Organization), and UNICEF, and in the holding of coordinating conferences among the operating staffs of the various agencies in the field of health. Such conferences have been held at the country level. They are held regularly in certain regions and have been held at the world level in Geneva.

In February 1953, for instance, a joint staff conference of the TCA health staff in Africa and Asia and the WHO headquarters and regional staffs was held in Geneva. It has led to a depth of understanding and intimacy of relationship which could be attained in no other way.

In health it is fair to say that under the leadership of the World Health Organization the various national and international programs have become, in a very real sense, a single, unified movement with a common goal and common methods of attaining that goal.

During 1952, 12,600 villages, one-third of all the villages in Iran, in which are the homes of some 4 million Iranians, were treated with DDT. The report of the United States Director of Technical Cooperation—the Point IV

"Nations must work together for their common good against their common enemies—violence, poverty, ignorance and disease. We can't take them on one at a time because they are all tied together, and we can't act alone because we're all tied together. The late Justice Holmes said that continuity with the past is not a duty. It is only a necessity. I would say the same of international cooperation. It is not a duty. It is only a necessity."

—Ambassador James J. Wadsworth,
Deputy United States Representative to the
United Nations

program—which contributed substantial sums to this campaign, includes the following statement:

"This campaign against malaria in Iran is a truly international effort. Iran's Ministry of Health, Institute of Malariology of the University of Tehran School of Medical Sciences, the World Health Organization's Malaria Control Advisory Team consisting of a malariologist, an entomologist and a sanitary engineer, and Point IV have all joined in this program in Iran. Cooperation and coordination has been excellent considering the great area of Iran, poor communications and usually bad roads, and other organizational problems of an undertaking as great as this program. The WHO team are 'tops' and to them must go much of the credit for the technological success."

Indeed, international cooperation is a living reality. In the World Health Organization, there is represented something new and fine which has come into the world since the Yankee trader took his profits from "mortally sickly" Haiti. We, as United States citizens, can take a great measure of satisfaction in this change to which we, as a nation and a people, have contributed so much of goods and spirit. We can take pride in America's part in building WHO. We can explain this to our fellow citizens so that they too may find satisfaction in a job well done and worth pushing ever forward.

Two Cooperative Projects of WHO and UNICEF

By S. M. KEENEY

IN ASIA, the World Health Organization and the United Nations International Children's Emergency Fund (UNICEF) work hand in hand on 50 projects in 15 countries in which UNICEF has invested \$20,000,000 in supplies and WHO is supplying 100 professional personnel. These projects range from training projects, in which the main investment is for personnel, to mass campaigns where the foreign technical personnel may be only 5 percent of the project.

Our approach is to keep in mind always that the projects are not those of UNICEF or WHO. We are working together to help governments. It is even more important to remember that both our agencies and the government are merely the means of getting a job done for the people. The people, in fact, must be an essential fourth partner for, unless their cooperation is active, in the long run we shall fail.

UNICEF administratively is a small organization in Asia. We have only about one international staff member for every million dollars. We have one regional office, in Bangkok, Thailand, which covers the projects in the Western Pacific and Southeast Asia WHO regions, together with Pakistan, which falls into the Eastern Mediterranean region of WHO. The reason UNICEF has only one regional office is that it is feasible and much cheaper to handle supply problems for the entire area; WHO must deploy professional people and cannot work over so large an area. Examples will illustrate the cooperation which exists between WHO and UNICEF.

Mr. Keeney is director for the Southeast Asia region—with headquarters at Bangkok—of the United Nations International Children's Emergency Fund.

Yaws in Indonesia

A yaws project in Indonesia began about 3 years ago and has treated to date about 700,000 cases found among some 7 million people. The job is only 10 percent done, for there are at least 7 million cases in the islands among the 75 million population.

UNICEF has made a first allocation of \$1,200,000 and has just voted an additional \$450,000 which will be enough to carry the project at least through 1955. The Government has paid all the local expenses and, beginning this year, will pay for one-third of the penicillin to be used for adults.

Joint Job from the Start

To start the project 3 years ago, WHO sent a specialist to consult with the Government and to make preliminary recommendations. Dr. Thomas Parran of the University of Pittsburgh Graduate School of Public Health confirmed this need in a general study of urgent needs in Asia. Several of us from UNICEF went in to work out the administrative details. From the beginning, it was thus a cooperative job. A full-time foreign clinical specialist and a serologist were maintained for 2 years. The rest of the work has been done by the Indonesians themselves, and in the last year the only international WHO member has been the serologist. This does not mean, however, that the project does not have technical supervision. A statistician was necessary last year for some months to examine the records and to make suggestions for improving them. He did a most acceptable job and is asked to return this year.

The first 2 years' work proved that, even with the very few dollars, it was possible to organize

teams of male nurses who could do a thoroughly acceptable job cleaning out yaws, village by village. The trouble was that there was not even enough nurses. It was therefore determined to bring into the plan eventually all of the polyclinics, of which there are some 1,200 scattered over Indonesia, and to use the male attendant to do the injections under the supervision of the regency physician. Something more was needed, however—someone to find the cases in the villages and bring them together for treatment. This person has only a high school education and perhaps only 3 months' training, but he is carefully picked so that he is acceptable to the village, and he works through the village headman.

This plan was tested under the guidance of Dr. M. Soetopo, a member of the WHO Expert Committee and a leading venereologist in Surabaya. Careful preliminary tests were made to find out whether the system would work at all, how effective it would be, how fast the work could be done, and what the cost would be. The tests were simple, but carefully done, because on that the whole expansion depended.

Bangkok Yaws Conference

Here again WHO came into the picture. These tests were carefully examined in the first International Yaws Conference held in Bangkok March 1952, with 60 specialists in attendance from most countries that have yaws. There was much discussion of the conditions that must be put on work that has to be done with so little medical supervision.

The conference was not satisfied to discuss the papers brought from Indonesia. A special committee of three made a special study on the spot of the methods that were being used. They suggested a number of technical changes that ought to be made, but, in general, gave their hearty approval to the plan and urged that it be expanded to treat at least a million cases a year.

We are now in the midst of that expansion. The whole job is being done by the Indonesians themselves. There is on the spot, however, as country representative from WHO, the previous regional specialist on yaws who regularly consults with the national team leader. In fact,

the team leader, the WHO representative and the UNICEF mission chief work together to develop a sound and feasible administrative plan.

It is still too early to determine the results. The plan is beginning, however, on schedule; almost 100 local units have already been started; and by the end of 1953 the goal is 300. The rate of treatments per month is expected to rise from about 25,000 to at least 50,000 by the end of this year, and to at least 75,000 a month next year. We are still far from the goal, but we are on the way.

BCG Work in India

Largely because of the amount of transport needed, the UNICEF investment in this project is relatively high. The work of the professional staff, however, has been more important in BCG work than in yaws, because the secret of success is, even more than in yaws, that of rapid and effective organization: to assemble millions of children quickly and get the highest percentage of them back to have their tests read.

The beginnings of this work in India and in Asia in general were discouraging. There was considerable opposition, and much educational work needed to be done. Greater obstacles were poverty, the lack of roads, the heat, and the monsoon. It has been found, however, that careful preparatory work does make possible the organization of successful campaigns under every condition except that of civil war, which occasionally holds up matters temporarily.

Against these discouraging beginnings is the record of recent accomplishment in a new type of campaign in Delhi State. The goal was 700,000 children to be tested within a month. All the local health forces available were marshaled, and several teams were brought in from neighboring States. This was partly to recognize good work done in their local States and, as a bonus, to give them a chance to see the capital.

Tests and Vaccinations

Fortunately, the weather was good and the children relatively easy to gather. The most effective method, long since worked out, was

to provide a little music, and all the school bands in town were marshaled. Where a band wasn't available, an energetic drummer with a double-headed drum was quite adequate to get the crowd together. Public address speakers, mounted on jeeps, patrolled the area telling the people that the test was of no use unless they came back to have it read and to be vaccinated, if necessary.

When the campaign was closed on March 21, 1953, the goal had been passed, and the number actually tested was 751,000. The percentage of return was 67, which is almost the average for a slower campaign. One team of 11 persons had tested 16,500 children in a single day. This means, of course, that the team itself did only *the actual test; the rest of the community* brought the children and took them away.

The number of children expected to be tested under this program in India in April 1953 will be more than a million, and in all the area rather more than one and a half million persons. Our goal for the year is 16 million, and we think we will pass it. We are, however, desperately in need of a few more physicians, for several wholly new programs await only a team leader without whom the program cannot start.

It Can Be Done—Together

Three years ago we were about ready to say that mass programs among the villages of Asia were not feasible. We know now that, even

with the tiny budgets available, they are quite possible if we face the local conditions realistically. To do a successful job, we must have a strong national leader in charge, a few good international personnel specially trained and with rugged constitutions. Given this, and enough transport and a steady supply of vaccine, the job can be done. It is above all things, however, a team job. The government cannot do it without help from outside. WHO cannot do it without money for equipment and supplies from UNICEF. UNICEF certainly cannot do it without WHO-trained personnel.

In the struggle to get money for our budgets, the separate agencies of the United Nations are tempted to talk only of themselves in order to catch the ears, against all the competing din of other claimants, of the people who vote the money. This may be necessary at times, but it ought not to be the pattern. Professional advice is not enough; supplies alone are not enough; but when competent technical advice and imported supplies are offered together, then things begin to happen. And it is only when things begin to happen in the countries receiving the aid that they begin to understand that the United Nations means business. The endless headlines emphasizing international quarrels do not sell the United Nations to Asia. They are likely to say: "A plague on both your houses!" If we want to impress them, it will be with deeds—not words.

Radiation Exposure in the United States

Reactor-Produced Radioactive Isotopes

By SAMUEL C. INGRAHAM, II, M.D., M. P.H., JAMES G. TERRILL, Jr., C.E., M.B.,
and DADE W. MOELLER, M.S.

RADIOACTIVE ISOTOPES "in the types and quantities producible in a nuclear reactor create health and safety problems which are not necessarily limited to the individual user, but are a matter of public interest as well." This statement was made by the United States Atomic Energy Commission (1), which is responsible for distributing and supervising the use of all reactor-produced radioactive isotopes in this country. It demonstrates the need for continual vigilance relative to these materials.

Although the radiation exposure received by persons using radioactive isotopes appears to be of a relatively low level, it is a fact that their use is becoming more widespread. Today more than 1,100 medical institutions, colleges and

universities, industrial firms, Federal and State laboratories, foundations, institutes, and physicians have used or are using these materials. About 7,500 persons are directly involved in their use, besides the persons who are receiving medical applications of radioactive isotopes.

Reviewed here are data from the literature on the amount of radioactive isotopes in use, regulations concerning shipment and use, and levels of radiation exposure received by persons involved. These data supplement an earlier presentation by the authors on the principal sources of radiation exposure in the United States (2).

Distribution

The Isotopes Division of the United States Atomic Energy Commission distributed only 96 curies of radioactive isotopes in fiscal 1947, the first year distributions were made. Each year since that date, the amount shipped has increased substantially. A total of 4,250 curies had been distributed by June 30, 1952. Of this amount, almost 1,800 curies were radioiodine and radiophosphorus, which decay rapidly.

Dr. Ingraham is assistant chief of the radiological health branch, Division of Engineering Resources, Bureau of State Services, Public Health Service. Mr. Terrill is acting chief of the branch, and Mr. Moeller is on the staff. This report was prepared after consultation with the Isotopes Division of the U. S. Atomic Energy Commission, Oak Ridge, Tenn.

An additional 2,200 curies were radiocobalt, which is distributed as a sealed source. Less than 1 percent of all the radioactive material shipped was in the very hazardous class of radiomaterials, as defined by the National Committee on Radiation Protection.

More than 31,000 shipments of radioactive isotopes were made from the Oak Ridge National Laboratory between August 1946 and November 1952. The number of shipments during this period for each principal isotope is as follows (3):

<i>Radioactive isotope</i>	<i>Number of shipments</i>
Iodine-131-----	12, 058
Phosphorus-32-----	8, 784
Carbon-14-----	1, 381
Sodium-24-----	1, 218
Sulfur-35-----	680
Gold-198, -199-----	963
Calcium-45-----	468
Iron-55, -59-----	415
Cobalt-60-----	634
Potassium-42-----	506
Strontium-89, -90-----	234
Other-----	4, 033
Total-----	31, 374

The following data show the distribution of radioactive isotopes from August 1946 through June 1951 according to use (1):

<i>Field of utilization</i>	<i>Number of shipments</i>
Medical therapy-----	8, 981
Animal physiology-----	4, 328
Physics-----	1, 274
Chemistry-----	1, 040
Plant physiology-----	877
Industrial research-----	784
Bacteriology-----	321
Other-----	1, 300
Total-----	18, 905

Transportation

The Interstate Commerce Commission is empowered to formulate rules and regulations to assure the safe interstate transportation of radioactive materials by commercial motor vehicle, rail, and water carrier. They cooperate in the formulation of regulations with the American Association of Railroads, the United States Coast Guard, and the Civil Aeronautics Board, which act as the enforcement agencies in their respective fields. Regulations governing postal shipment of radioactive materials are both formulated and enforced by the United States Post Office Department and are adminis-

tratively independent of the Interstate Commerce Commission. However, the Post Office must collate their regulations with those of the Commission since several carriers may be involved in any one shipment process. These regulations attempt to protect people and films from exposure to radiation and at the same time to limit the cost and burden of shielding materials (4).

Interstate Commerce Commission regulations limit the quantity of radioactive substance packed in 1 outside container to 2 curies, except by special arrangement. They limit the allowable radiation from the shipping container to 200 milliroentgens per hour at the surface and 10 milliroentgens per hour at a distance of 1 meter. Both of these requirements must be satisfied. Shipments are exempt from these regulations if they contain 0.1 millicurie or less of radioactive material and meet other special requirements that overcome the radiation hazard. The Atomic Energy Commission has reported approximately 95 percent of all shipments have had an external radiation level of less than 0.015 roentgen per hour at the surface of the container.

The contractor at the Atomic Energy Commission installation assumes responsibility for packaging isotopes, in accordance with the regulations. Generally, the only concern is transporting the material to the user from the installation. However, the recent trend for the prime receiver of radioactive isotopes, such as a large central hospital, to process and redistribute them to secondary receivers, such as smaller hospitals, creates additional transportation problems.

Control of Utilization

The Atomic Energy Commission, exercising its responsibility under the Atomic Energy Act of 1946 (Public Law 585, 79th Cong. 2d sess.), has to date accomplished control of radioactive isotope distribution and use by an allocation or "licensing" procedure. The radioactive materials distributed by the Commission have been made available only to those who have the necessary prerequisites in training and equipment to handle the materials safely (1). A secondary receiver is, of course, subject to the

Production of Artificial Radioactive Isotopes in a Low Power Atomic Reactor

The top sketch shows the reactor housing, control stations, and other equipment as they would appear in use by industry, universities, and other research institutions. At left is a cutaway drawing of the reactor. This "atomic furnace" can be operated at a rate of 8 hours a day, 5 days a week, for 10 years before being recharged. It was designed for the Atomic Energy Commission. (Illustrations courtesy of North American Aviation, Inc.)

same regulations in the handling and usage of the radioisotopes as is the primary receiver.

The allocation control procedure is complemented by the activities of an advisory field service. Radiological safety specialists visit users and offer advice on the design of radiochemical laboratories, remote handling equipment, and shielding, decontamination procedures, standardization of measurements, and the safe use and disposal of radioactive isotopes. The practices, equipment, and records of the users are reviewed with particular emphasis on factors involved in radiation safety (5).

According to the Atomic Energy Commission, increased use of radioactive isotopes in the future will necessitate supplementation of the present centralized method of control by supervision at the point of use. The responsibility of the Commission for the control of the hazards from "byproduct materials," as described in the Atomic Energy Act of 1946, is being supplemented by a joint Atomic Energy Commission-Public Health Service program of assisting state and local health organizations to assume responsibility for the day-to-day surveillance of Commission-distributed radioactive isotopes.

Exposures to Radiation

In handling and preparing radioactive isotopes, the user and the personnel nearby are potentially exposed to internal and external radiation. When radioactive isotopes are used for medical diagnosis and therapy, the patient too receives exposure. It should be emphasized, however, that the exposure received by the patient in the medical application of radioactive isotopes is a planned exposure and is administered for his net medical benefit.

The most persistent hazard to health associated with the use of these materials is the possibility of internal radiation as the result of radioactive substances being accidentally ingested, inhaled, or absorbed. The enormous potency of very small amounts within the body is emphasized by the recommended standards (6), which are summarized in table 1.

Since the determination of the amount of radioactive material within a person's body is, at present, a complicated procedure, few data

Table 1. Maximum permissible levels for specific radioactive isotopes

Radioactive isotopes	In the body (micro-curie)	In liquid media (micro-curie per ml.)	In air (micro-curie per ml.)
Iodine-131-----	0.3	3×10^{-5}	3×10^{-4}
Phosphorus-32----	10	2×10^{-4}	1×10^{-7}
Carbon-14-----	{ 250 (fat) 1,500 (bone)	3×10^{-3}	1×10^{-4}
Sodium-24-----	15	4×10^{-3}	5×10^{-7}
Cobalt-60-----	3	8×10^{-3}	2×10^{-3}
Strontium-89-----	2	2×10^{-2}	1×10^{-3}
Strontium-90 (+ Yttrium-90)---	1	7×10^{-5}	2×10^{-3}
		8×10^{-7}	2×10^{-10}

are available regarding exposures due to internal radiation. Data on external radiation exposures have, however, been reported. One report concerns the weekly exposures, as measured by film badges, of 140 persons working in radioisotopes laboratories. Of 4,750 film badges worn by these persons during an 8-month period, only 1 indicated a weekly exposure greater than 0.3 roentgen, the maximum permissible weekly dose. More than 4,700 badges indicated weekly exposures of less than 0.05 roentgen (?).

Radioactive Isotopes in Industry

Radioactive isotopes are being used in a variety of research problems, in radiography, and in such testing and measuring devices as thickness and liquid level gauges (2). The principal radioisotopes used in industry, some of their properties, and examples of their use are listed in table 2. The figures given in the third column illustrate the enormous potency of small quantities of the radioactive isotopes; they are not necessarily related to the quantities actually used in the examples cited.

Radioactive Isotopes in Medicine

Radioactive isotopes are used both internally and externally for medical diagnosis and therapy. In this report, intracavitary and interstitial uses of sealed sources of radioactive isotopes are considered external since the radioactive material does not leave the container in which it is sealed even though it is within the body. Some of the better known medical ap-

plications of radioactive isotopes are as follows (8):

Sodium-24—Correlation of sodium turnover with congestive heart failure; differentiation of normal and restricted blood flow; radio-cardiography (determining pumping qualities of the heart).

Phosphorus-32—Determination of extent of tumor mass in brain tumor surgery; treatment of polycythemia vera and chronic leukemia.

Iodine-131 in diiodofluorescein—Location of certain brain tumors.

Iodine-131—Detection of hyperthyroidism; location of thyroid cancer offshoots, or metastases; treatment of hyperthyroidism, thyroid cancer, and metastases.

Cobalt-60—Interstitial sources for treating accessible tumors and teletherapy units for deep-seated tumors.

Strontium-90—Beta-ray source for treating surface lesions.

Gold-198 (colloidal)—Treatment of subsurface tumors of lymphoid system and chronic leukemia.

Internal Sources

Iodine-131 is the most widely used radioactive isotope for medical purposes, and phosphorus-32 ranks second. A medium-sized hospital (150 to 300 beds) participating in the isotopes program will have some 35 millicuries of radioactive iodine on hand. A large hospital (400 to 700 beds) may have 200 to 300 millicuries of this material, according to the January 1951 report of the Joint Fire and Ma-

rinc Insurance Committee on Radiation of the major private underwriting and insurance associations.

Radioiodine given orally is rapidly absorbed from the gastrointestinal tract and distributed throughout the body. In normal persons, the thyroid gland will fix 10 to 25 percent of the dose and the remainder will be excreted in the urine within 24 hours. In patients with hyperthyroidism, 50 to 80 percent of the dose may be fixed by the thyroid (9).

Radiophosphorus is given either orally or intravenously. About 75 percent of the oral dose is absorbed and the remainder is lost in the feces. Of the amount reaching the circulatory system, whether the dose is administered orally or intravenously, 20 to 40 percent is excreted quickly through the kidneys, and the rest is distributed throughout the body (9).

Thus, in the medical application of radioactive isotopes the whole body is subjected to some radiation, most of which occurs during the first day or so after the dose is given. For example, for each millicurie of radioactive phosphorus administered to a patient, the resultant total-body irradiation is 10 roentgen equivalents physical, taking into account the half life of the isotope and the excretion of part of the dose (9).

Table 3 presents the range of the usual doses of iodine-131 and phosphorus-32 and the theoretical exposure resulting in the critical organ of the body. Calculations were made from published data, as indicated.

Table 2. Radioactive isotopes in industry

Radioactive isotope	Half life	Millicuries of radioactive isotope per gram of total element as available	Example of use
Cobalt-60.....	5.3 years.....	34 to 5,000.....	Radiography.
Selenium-75.....	127 days.....	3.3 to 100.....	
Tantalum-182.....	117 days.....	105 to 1,500.....	
Carbon-14.....	5,720 years.....	250 to 1,500.....	Thickness gauge.
Strontium-90.....	25 years.....	¹ 160,000.....	
Barium-140.....	12.8 days.....	¹ 72,000,000.....	Mark interfaces and measure intermixing in pipelines.
Antimony-124.....	60 days.....	12 to 1,500.....	
Iron-59.....	46.3 days.....	500 to 1,500.....	Measure engine wear.
Calcium-45.....	152 days.....	0.2 to ¹ 19,000,000.....	Evaluate detergents.
Yttrium-90.....	2.54 days.....	115.....	Used as tracer in dyeing process.
Lanthanum-140.....	40 hours.....	525.....	Determine sulfuric acid content in chromium plating solutions.

¹ Approximate.

Table 3. Range of radiation exposures from diagnostic and therapeutic doses of radioactive phosphorus and iodine

Radioactive isotope	Disease	Average total oral dose ¹ (microcuries)		Selected critical organ	Total radiation exposure to selected critical organ ² (roentgens or roentgen equivalents physical)	
		Diagnosis	Therapy		Diagnosis	Therapy
Iodine-131.	Hyperthyroidism.	100 to 300 (usually 100).	3,000 to 10,000.	Thyroid. ³	⁴ 100 to 1,100.	⁴ 11,000 to 40,000.
	Thyroid cancer.	1,000 to 3,000.	⁵ 50,000 to 250,000.		⁴ 4,000 to 11,000.	⁶ 24,000 to 300,000.
Phosphorus-32.	Blood dyscrasias.	100 to 500.	3,000 to 10,000.	Bone. ⁷	2 to 7.	40 to 130.
				Muscle.	1 to 3.	20 to 65.

isotopes in biology and medicine. Madison, University of Wisconsin Press, 1948, p. 377-394.

See also footnote 1.

³ Average thyroid weight of 30 grams used in calculations.

⁴ Assumes 75 percent absorption of oral dose in thyroid.

⁵ Usually consists of a series of smaller doses.

⁶ Assumes 10 to 30 percent absorption of oral dose in thyroid.

⁷ Weight of bones in average man assumed to be 7,000 grams.

As can be seen from these data, exceptions to the standards established for permissible levels of radiation are made when radioactive isotopes are used clinically since the intent here is to produce or measure biological changes rather than to avoid them. In certain therapeutic applications of radioactive isotopes, the total-body irradiation may be 75 to 100 roentgens.

Powell (10) reports that patients who have received internal applications of radioactive materials do not ordinarily constitute a significant source of external radiation. However, when a therapeutic dose of a gamma-emitting isotope, such as iodine-131, has been given, the maximum permissible dose level, 0.3 roentgen in air per week or 7.5 milliroentgens per hour for a 40-hour week, may be found as far away as several feet from the patient. It has been recommended as a public health precaution that "patients who receive large doses of iodine-131 or gold-198 should be hospitalized until the total residual activity in the body is not over 30 millicuries" (11).

Periodic radiation surveys of the areas in the hospital where these patients are located may be required, and the wearing of film badges by the nurses caring for them is recommended (12). The external radiation hazard may be minimized through use of the protective measures—distance, time, and shielding.

The patient who has been given one or more doses of a radioactive isotope requires special supervision and handling if nurses and other personnel are not to become contaminated. It is recommended that rubber gloves be worn while bathing the patient (12). In addition, such problems as the contamination of bed linen must be considered. These articles may require special storage or laundering procedures (10).

External Sources

Strontium-90 and cobalt-60 are the principal radioactive isotopes used in medical therapy as external sources of radiation. Beta-ray applicators (strontium-90) are available for the treatment of certain eye conditions. Cobalt-60

is available in the form of large shielded concentrated sources for deep therapy and in the form of small needle sources for intracavitary and interstitial therapy. The Atomic Energy Commission has authorized 12 applicants to use teletherapy units, amounting to a total of some 16,000 curies. Three of these units are already in operation. Twenty-two applicants have been authorized to use small sources, such as needles, totaling some 7,600 millicuries.

Dosages administered to the patient are of the order of 6,000 to 7,000 roentgens. Such therapy, however, is used only for conditions demanding drastic measures, and the exposure is limited to a small section of the patient's body.

Wastes

Wastes from the use of radioactive isotopes by industry, the medical profession, and research laboratories could create health hazards to persons outside the installations using them. However, if the recommendations for the disposal of the wastes from the use of phosphorus-32 and iodine-131 made by the Subcommittee on Waste Disposal and Decontamination, National Committee on Radiation Protection (13), are followed, few, if any, hazards should arise. Ruchhoft and Feitelberg (14) have shown that the dilution needed to reduce the activity of liquid isotopic wastes from hospitals to safe limits is generally available, and, therefore, their disposal is not a major problem. Radioactive isotopes, such as cobalt-60, which are distributed as sealed sources normally have no waste disposal problems.

Conclusion

It would appear that the radiation exposure in the United States due to reactor-produced radioactive isotopes distributed by the Atomic Energy Commission is currently limited to relatively few people and is of a relatively low level. However, there is no indication of a decline in the use of these materials, but rather there is a strong probability that their use will become much more extensive. Further study of radiation exposure from this source as data become available may be required.

Anthrax in the United States

By JAMES H. STEELE, D.V.M., M.P.H., and RAYMOND J. HELVIG, D.V.M., M.P.H.

ANTHRAX TODAY does not seem to present the serious public health problem of former years. In 1951, only 60 cases were reported to the National Office of Vital Statistics, Public Health Service. Forty-five, or 75 per cent, of these cases occurred in the northeastern States and were attributed to occupational exposure. There were less than 15 human cases in other States. The highest incidence occurred in January, February, March, April, May, and November. During the period 1945 to 1951, inclusive, 872 cases of human anthrax occurred, most of them in the 7 northeastern States, where industrial exposure is usually stated to be the source of infection (table 1). In the remaining 41 States, 63 cases were reported, of which 29 (21 farmers and 8 veterinarians) were due to agricultural exposure. Twenty States reported no cases of anthrax in the period 1945-51; 24 reported less than 10 cases; 1, less than 25; 2, less than 100; and 1, more than 100.

The 5 cases reported in Florida were attributed to an outbreak of bovine anthrax in the fall of 1951. The individuals involved were a cowboy who skinned a cow, dead of anthrax, two veterinarians who vaccinated cattle in this area, a laboratory technician who handled a suspected specimen, and a child in a nearby town. In Arkansas 5 of 9 cases were associated with the skinning of a cow that had died suddenly. The farmer was assisted by his family and neighbors in the salvage operation. The 2 cases

reported in Kentucky were in farmers who removed the hides from mules that had died of anthrax. The mule carcasses then were fed to swine, and the swine developed anthrax. In California, one of the cases occurred in a sheepherder who sheared infected sheep. On different occasions, three California veterinarians contracted the disease while performing post mortems on a cow, dead of anthrax. In New Jersey, a farmer who killed and dressed an infected heifer developed the disease. Most of the human cases reported in the western and southern States occurred under similar conditions. All of the cases were of the cutaneous type. There are no records of human anthrax caused by the ingestion of contaminated milk or meat in the United States in recent years.

During 1952 provisional reports indicated that there were 42 human cases of anthrax in the United States. This compares with 60 in 1951. Three of the 1952 cases occurred in Ohio: in a veterinarian, a laboratory technician who handled specimens, and a carpenter who worked in a feed mill where contaminated feed had been handled.

Animal Anthrax

During the period 1945 to 1950, inclusive, 658 outbreaks of animal anthrax were reported from 32 States with estimated losses of 8,504 head of livestock. Occurrences in new areas were reported from 51 counties in 16 States. In 1951, a noticeable increase in outbreaks was observed. There were 483 outbreaks in 25 States involving 113 counties, with a loss of 2,753 animals. Three-fourths as many outbreaks occurred in 1951 as in the 6-year period 1945-50; however, the total number of animal losses was

less than in 1946 when there was a severe epizootic in Louisiana which killed over 3,000 animals. Missouri had the highest losses in 1951, with 694 animal deaths, of which 440 were in horses and mules. Fairly large losses were re-

ported in California, Florida, Illinois, Iowa, Kentucky, Nevada, Tennessee, and Texas.

An unusual feature in the 1951 losses was the great number of widely scattered outbreaks in swine. The Bureau of Animal Industry, U. S.

Department of Agriculture, reported 1,088 swine deaths compared to 1,001 deaths in cattle. The greatest swine losses were in Illinois, Iowa, Missouri, and Kentucky. Coincident with the increased number of swine cases was the condemnation of 232 infected carcasses by the Federal Meat Inspection Service. These 232 cases were more than half the total of 367 hogs and 39 cattle condemned because of anthrax during the entire period July 1945 through December 1951 in establishments under the supervision of the inspection service.

In 1951, outbreaks in animals were reported in 15 States, in 51 counties which previously had had no history of the disease: Indiana, Kentucky, Mississippi, New Jersey, and Ohio, 1 each; Florida, Minnesota, and Oklahoma, 2 each; Louisiana, Tennessee, and Wisconsin, 3 each; Missouri, 4; Texas, 6; Illinois, 10; and Iowa, 11. No human cases were attributed to any of the swine outbreaks. Wisconsin also reported 102 cases in mink. These were thought to have been caused by ingestion of infected animal feed.

The Florida outbreak was the first since 1928. The disease involved deer, and beef and dairy cattle. The cause was not determined. Bonemeal was suspected, but laboratory examination did not reveal *Bacillus anthracis*.

Although swine are considered to be more resistant to anthrax than any other livestock species, the disease is not uncommon in these animals in the areas where the infection exists enzootically. Infections in swine have also oc-

curred in noninfected areas because of consumption of contaminated feed, but cases usually appear after infection of other livestock. Infection in swine usually results from their feeding on carcasses of animals dead of anthrax, from following infected animals, or from deep rooting in contaminated pastures during warm weather. Anthrax in swine may take many forms including the acute or the chronic forms with characteristic symptoms of septicemia or glossitis with enlargement of the cervical lymph nodes. In addition, mild or latent cases often occur which are not readily diagnosed. The swine outbreaks that occurred in the midwest in 1951 were all on premises hitherto considered free from infection and far removed from enzootic areas. Although the Bureau of Animal Industry, in cooperation with State livestock sanitary authorities, carried on special investigations, they failed to establish a definite source of infection. The history of some cases suggested that contaminated mixed feed may have been the source of infection. Laboratory examination of suspected feed samples failed to reveal *B. anthracis*.

The map illustrates the prevalence of anthrax in cattle, swine, horses, sheep, and mink in 1952. The stippled areas are the known enzootic areas. These areas were not involved in the swine outbreaks. Twenty States did not report any animal anthrax. The largest number of cases was reported in swine in the midwestern States (table 2) during the winter and early spring. This unusual seasonal occurrence is of special significance, inasmuch as anthrax is usually considered a warm weather disease among animals. Ohio had outbreaks in 56 counties involving over 280 farms. Indiana reported cases in 46 counties on 106 farms. Illinois reported 50 counties and 117 farms with anthrax cases. Michigan had 17 counties and 31 farms with infection. Wisconsin reported anthrax in 17 counties on 35 farms. All of these States reported the isolation of *B. anthracis* from bonemeal and attributed most of their outbreaks to contaminated bonemeal. It is important to observe that none of these States is considered to be an anthrax enzootic area. Previous to the outbreaks of late 1951 and early 1952, anthrax had not been reported in Indiana and Ohio for more than 20 years. Illinois and Wisconsin

had not had any cases for years, and Michigan had not had a case since 1916. Dr. H. J. Staffseth, Michigan State College, states in a personal communication that the 1916 case is the only known diagnosed case up to 1952. The outbreaks in Ohio, Indiana, and Illinois mainly involved swine, while those in Wisconsin and Michigan were mainly on dairy farms. Wisconsin also had additional cases in mink, as did New Jersey and New York.

Kansas reported bovine anthrax in February. In April, anthrax was reported in beef and dairy cattle on more than 100 farms. An investigation revealed that anthrax had occurred only in herds that had been vaccinated with bacterin. The incubation period was from 3 to 120 days.

In 1952, Georgia reported the first outbreak of anthrax in animals since prior to 1945. Bonemeal was suspected as the vehicle of infection but this was not proved.

Florida had a reoccurrence of anthrax in the summer of 1952 in the area where the 1951 outbreak was reported, and the 1952 outbreak

spread to noninfected areas. Anthrax following vaccination with a bacterin was also reported. Of 300 beef cattle vaccinated by a rancher, 15 developed symptoms of anthrax 4 to 8 weeks following inoculation; 7 died, 2 of them after the surviving affected animals were treated with 3 million units of penicillin daily. None of the 15 animals exhibited typical symptoms and at first the cattle were thought to have been bitten by a snake. An extensive swelling was noted around the site of inoculation behind the shoulder, which in some cases extended forward to the brisket and back to the udder. The course of disease extended over a number of days.

The Ohio swine outbreaks which began in February 1952 were studied by the Ohio Division of Animal Industry and the Ohio Department of Health. These investigations were the first to reveal that imported raw bonemeal was contaminated with *B. anthracis*. Illinois, Michigan, Indiana, Wisconsin, and Missouri reported isolation of anthrax spores from bonemeal samples. The bonemeal was traced to a

New York importer who had bought it in Belgium. Further investigation revealed that the bonemeal had been collected in Asia and southern Europe and brought to Belgium for reshipment to the United States and subsequent distribution in the midwest.

It is interesting to observe that nearly all the hogs involved were pregnant or nursing sows. This is readily explained by the fact that they were the only animals receiving a high protein-calcium ration which is recommended for the pregnant or nursing animal. Few or no cases were observed among other animals, except where some of the sow supplement ration was fed to other animals by mistake, or where through their own efforts, the animals were able to reach it.

The U. S. Department of Agriculture has adopted regulations prohibiting the importation of raw bonemeal. All bonemeal entering this country must now be sterilized at a temperature of 250° F. under 20 pounds of pressure. In addition, many States have adopted similar regulations.

One of the important observations made in the Ohio outbreak was that penicillin or other antibiotics are to be preferred to immunizing agents in the control of anthrax in swine. The administration of 6 million units of penicillin in oil proved very effective in the large sows which weighed from 200 to 400 pounds or more. Penicillin has been used successfully in the treatment of cattle also but is not recommended as a control measure in place of vaccination. In

A cow dead of anthrax. Note the great number of flies on the carcass. Virulent anthrax germs were found in flies taken from this and a partly incinerated carcass on the same ranch.

some bovine cases there have been relapses following the injection of penicillin. Aureomycin and terramycin were used with success.

Public Health

Even though anthrax is not readily transmitted to man, the numerous outbreaks of the disease in animals during the past 2 years have raised a number of public health questions. These questions include: What measures should be taken in handling milk from infected premises? How should meat animals from known infected farms be processed? What steps can be taken to prevent occupational disease among animal handlers? What procedures are recommended for animal disease control so as to remove any threat to public health?

Milk

The question of what to do with milk from a farm where anthrax has occurred in a milking herd or in other animals cannot be answered in all cases by a decision to quarantine the premises, but requires an examination of the problem at hand. As previously stated, there are no reports in the United States of the transmission of anthrax in milk to man. The results of unduly stringent quarantine regulations may tend to discourage reporting of anthrax, and such procedures may also present a serious economic problem to the dairyman. Some sizable nuisance problems have been known to develop when the milk from 500 or 600 cows was dumped on a farm in a warm climate.

The following recommendations have been formulated by the Public Health Service, with the assistance of the Bureau of Animal Industry of the U. S. Department of Agriculture, the Federal Food and Drug Administration, the Federal Civil Defense Administration, U. S. Livestock Sanitary Association, and the American Veterinary Medical Association.

The recommendations, which appear on pages 621 and 622, were transmitted February 4, 1953, by the Public Health Service to State and Territorial milk control authorities and others concerned. In forwarding these recommendations, Dr. Otis L. Anderson, chief of the Bureau of State Services, said:

"In the preparation of this material we have

One method of disposing of an anthrax-infected carcass by incineration

1. Saturate carcass with kerosene, crank case oil, or any other inflammable oil.
2. Cover carcass with a hayrack-full of straw.
3. Place two loads of heavy manure on top of the straw. Set afire. Add manure daily, or when necessary, to keep carcass covered until it is burned to a white ash.

attempted to be objective, realizing that: (a) there are no supported records in the literature of anthrax being transmitted to man through the consumption of milk; (b) unduly stringent quarantining measures may tend to discourage

reporting of anthrax thus nullifying control procedures; and (c) quarantining of dairy farms and exclusion of the entire milk supply from the market when a case occurs, may present a serious economic problem for the dairyman."

Anthrax Control Recommendations

1. All cases of anthrax, or suspected anthrax, should be reported by the dairyman to the local veterinarian and the health officer immediately, and such animals should be isolated completely from the herd and no milk from them sold until declared by a licensed veterinarian to be free from anthrax.

2. Where anthrax has occurred in the dairy herd and the animal or animals affected were stabled in the dairy barn:

a. All feed, hay, straw, manure and dirt likely to have been contaminated, the carcass of each animal dead from anthrax, and milk suspected of containing anthrax organisms or spores, should be disposed of promptly by complete burning or by deep (at least 6 feet) burial, under the direction or supervision of the State health department and/or the State livestock sanitary officials; the dust should be removed from the walls and ceilings; and the entire barn, including walls, ceilings, windows, floors, feed troughs, brooms, shovels, forks, spreaders, etc., should be thoroughly cleaned by washing with a 5-percent lye solution which should be left in contact with surfaces for at least 8 hours.

b. The temperatures of the remaining animals in the milking herd should be taken, immediately

prior to each milking, by a veterinarian or some other official person designated by the health officer to take such temperatures, for a period of 10 days following the removal or recovery of the last case of anthrax. The records of such temperatures should be available at all times for examination by the health officer, livestock sanitary officials, and others concerned. All animals having a temperature of 103° F. (cattle in hot, humid climates often have body temperatures of 103° F. without having any infection; in this case a recheck of the temperature in the late evening or early morning, would be indicated) or showing any other evidence of disease should be isolated from the milking herd immediately, and no milk from such animal should be mixed with the market milk supply until such suspects are declared by a licensed veterinarian to show no further evidence of disease.

c. The milk utensils which have been exposed to any secretion or excretion from the anthrax infected animal should be submerged in boiling water for a period of at least 30 minutes as soon as possible after contamination. This should be done under the supervision of the State or local health department, or the State livestock sanitary officials.

3. Where anthrax has occurred in any animal which has been in the same pasture or lot with the dairy cattle:

a. The entire herd should be removed from such lot, pasture, or portion of pasture, which is likely to have been contaminated by the infected animal, for such time as the State livestock sanitary authority deems necessary.

b. The temperatures of all of the cattle in the milking herd should be taken, immediately prior to each milking, by a veterinarian, or some other official person designated by the health officer to take such temperatures, for a period of 10 days following the removal or recovery of the last case of anthrax. The records of such temperatures should be available at all times for examination by the health officer and others concerned. All animals having a temperature of over 103° F. or showing any other evidence of disease, should be isolated from the milking herd immediately, and no milk from such animal mixed with the market milk supply until such suspects are declared by a licensed veterinarian to show no further evidence of disease.

4. Where anthrax has occurred in any animal on the dairy farm, but has been completely separated from the dairy herd; or where anthrax has occurred on adjoining farms:

a. The dairy herd should be kept under close observation for a period of at least 10 days and any evidence of anthrax reported immediately to the health officer and the local veterinarian.

5. Where dairy cattle are vaccinated for anthrax:

a. Such preventive vaccination should be done in a manner and with a product which is approved by the State livestock sanitary authority.

b. The temperatures of all animals vaccinated against anthrax should be taken, immediately prior to each milking, by a veterinarian or some other official person designated by the health officer to take such temperatures, for a period of 10 days following vaccination or presence of anthrax infection on the premises. The records of such temperatures should be available at all times for

examination by the health officer and others concerned. All animals having a temperature of over 103° F. or showing any other evidence of disease, should be isolated from the milking herd immediately, and no milk from such animal mixed with the market milk supply until such suspects are declared by a licensed veterinarian to show no further evidence of disease.

6. Where certain feeds are suspected by the State officials as being contaminated with anthrax organisms, such feed should be embargoed, or otherwise isolated from further use and distribution pending resolution of the doubts concerning the safety of the product. If found to be contaminated with anthrax organisms it either should be rendered free from contamination by a method acceptable to the State livestock sanitary authority, or it should be destroyed in accordance with 2a above. These determinations should be made as quickly as possible to reduce to a minimum, the physical and economic problems involved in embargoes.

It is realized that the livestock sanitary authorities in some States issue a quarantine that bars the movement of all animal products from the premises on which infection with anthrax has occurred, as a precautionary measure against the mechanical transmission of the disease from one premise to another. Therefore, it is imperative that the milk control authorities cooperate with the livestock sanitary authorities of the State concerned.

It is also important that local and State milk control officials, and the State and local livestock disease control officials, maintain close liaison with each other with regard to reporting of anthrax cases and anthrax control measures. This is necessary to provide for the maximum protection of the health of the persons who may have come in contact with infected animals on the farm, as well as for the protection of the milk consumer, and for the economic welfare of the dairy farmer. Persons handling anthrax infected animals, or materials, should be protected by rubber gloves and boots, which can subsequently be decontaminated with chemical disinfectants.

Other Control Measures

Processing meat animals from infected or quarantined farms should be done in abattoirs or packing plants that are under the supervision of the Federal Meat Inspection Service or a

local meat inspection service where a trained veterinary inspector is on duty. Although the transmission to man of anthrax in meat has never been reported in the United States, the foreign literature has carried numerous reports.

These reports have usually involved raw or semiraw meat products such as hard sausage.

Prevention of occupational anthrax among animal handlers can best be accomplished by health education. The farmer or animal handler must be cautioned against the treatment of sick animals and against attempts to salvage the hide of dead animals. The fact that no human cases occurred among farmers in Ohio can be explained by the farmer's practice of not making any effort to salvage a hog but of burying or burning it. He will skin a cow or horse and feed the carcass to the hogs. However, with the increasing availability of rendering plant pickups of dead animals, this latter practice is disappearing.

On a farm where anthrax is known to be present, the operator should receive instructions either from the attending veterinarian or the health department about how to protect his health. The most important thing to stress is personal hygiene and prompt medical care for any scratches, abrasions, or pimples that may appear.

Animal disease control is primarily the responsibility of the attending veterinarian and the livestock sanitary officials. The success of

antibiotics in the treatment of animal anthrax has provided an excellent weapon to deal with this problem. The live spore vaccines have been used extensively in this country with good results, although sometimes they fail. They should be used only on premises where infection has been proved or where there is strong evidence of disease. The antibiotics may replace the antiserum and bacterins that previously have been used in herds or droves adjacent to infected premises.

Conclusions

Anthrax is not readily transmitted to man. In the United States there is no report of its transmission to man by meat or milk. During 1951-52 animal anthrax cases increased, especially among swine. Some of these outbreaks were traced to contaminated bonemeal. However, even though there were more animal cases, the human cases continued to decline, and in 1952 numbered less than in 1951. Public health aspects are discussed as they relate to milk, meat, occupational disease, and animal disease control.

Anthrax Epidemic Curbed In Paraguay

Anthrax was temporarily halted in the countryside surrounding Coronel Oviedo, a town in Paraguay, after a 2-week fight this spring to prevent the spread of the virulent disease to 113,000 beef cattle. More than 1,300 cattle were given anti-anthrax vaccine. A quarantine area for the infected animals was established.

Barricades were erected on roads leading to Coronel Oviedo, and livestock growers taking their cattle to town either submitted them for vaccination or were required to return the animals to their properties. Even cart-drawing oxen were submitted to vaccination. Any slaughtered animals taken to the town for the market were examined by veterinarians for signs of disease.

Eighty head of cattle had died, but no human cases of anthrax had been found, as of April 17, 1953. Anthrax is greatly feared in Paraguay since livestock production is the backbone of the economy and beef cattle total almost 4 animals to each of the country's 1,500,000 population, according to the news report released in April by the Institute of Inter-American Affairs.

The discovery of the sudden death of 40 cattle in Coronel Oviedo on March 14, 1953, brought immediate assistance to the area from the Technical Cooperation Administration offices located 87 miles away in Asuncion. Laboratory analysis of the ear of a dead animal confirmed the outbreak of anthrax, the first for the area in recent years.

The Interest of Public Health in Diabetes

By MALCOLM J. FORD, M.D., M.P.H.

IN DEALING WITH diabetes mellitus, we are dealing with a disease "so widespread as to make public action . . . the only hope for a successful attack" (1). According to the best estimates, some 2,230,000 persons in the United States have diabetes, and only slightly more than half of these people know that they have the disease. Since diabetes occurs more often among older persons, prevalence of the disease, which today is approximately 15 per 1,000 population, can be expected to increase progressively as our older population continues to grow in number.

Mortality data provide two notable facts about diabetes: First, estimates for the year 1951 reveal that diabetes accounted for approximately 25,000 deaths in the United States—only about 5,000 fewer than the number of deaths estimated for tuberculosis (2). Second, diabetes has moved from twenty-first place among causes of death in 1900 to tenth place in 1950 (taking into account changes in classification of cause of death since 1900 and omitting all ill-defined causes).

With the threat of communicable diseases substantially diminished, the growing problem of chronic diseases stands out as the principal challenge and a most urgent responsibility for

the public health worker. The record of progress against the chronic diseases in the future will be more and more critical in determining the standard of health which we as a Nation shall achieve.

Public health is especially concerned with the prevention of disease—prevention either in the primary sense of preventing the occurrence of the disease, or in the secondary sense of preventing progression of the disease from an early stage to a more severe one.

As is true of many of the chronic diseases, primary prevention of diabetes is as yet an unfulfilled objective. It is now confined to measures suggested by the epidemiology of the disease. The incidence of diabetes is higher among overweight people than among those whose weight is normal or below normal; therefore, discouragement of overweight is in a sense a measure to prevent diabetes. Diabetes appears to run in families; therefore, the advisability of marriage between persons from diabetic families is a question to be considered in terms of preventing the disease. But without more basic knowledge of the cause of diabetes, we cannot depend upon preventing its occurrence.

Secondary prevention of diabetes—preventing the complications which account for a large proportion of the disability and death due to the disease—can, however, be undertaken with definite hope of success. Our broadening knowledge of the nature of diabetes makes feasible an intensive program in which the public health and medical professions can participate. High diabetes morbidity and mortality emphasize the necessity for action.

Case-finding procedures in diabetes are relatively simple and fast, and a variety of tests is

Dr. Ford, chief of the heart section of the Division of Chronic Disease and Tuberculosis, has served as medical officer in charge of a Public Health Service diabetes demonstration unit in Jacksonville, Fla., and as director of the division of nutrition and diabetes control of the Florida State Board of Health. He presented this paper before the Chronic Disease Conference for Nurses which was held in Atlanta, Ga., in November 1952.

available for this purpose. Of all the chronic diseases, diabetes is one of the easiest to diagnose, and, thanks to insulin and diet, one of the easiest to control in the individual patient, provided the patient understands the relatively simple treatment measures and cooperates fully with his physician.

Diabetes, a condition in which the body's ability to use and store carbohydrates is impaired, is most likely to be found in persons over 40 years of age, in the obese, or in those who have a history of diabetes in the family. Because mild diabetes does not necessarily produce symptoms recognizable to the patient, it may be present for some time before it is discovered. Usually diabetes becomes serious when the diabetic patient does not know of his condition or when, once knowing, he allows his condition to get out of control. Through case-finding programs the diabetic person can be sent to his physician for care while his disease is in an early stage. Under continued medical supervision, he can learn how to remain a contributing member of society.

During the past few years, a definite pattern for diabetes control has been evolving, and activity areas have been staked out: case finding and referral for care, patient and professional education, and education of the general public designed to disseminate the facts and to encourage a positive attitude regarding diabetes.

Community Detection Programs

The progression of unrecognized and uncontrolled diabetes results all too often in serious complications. The insidious development of the disease calls for aggressive case-finding efforts. For this, community action is needed.

A number of diabetes case-finding programs have been conducted during recent years. Many communities have undertaken urine-testing programs during a special "diabetes week," with varying intensity of campaigns and degree of coverage. In Connecticut, a diabetes detection program has been undertaken each fall since 1948 (3). The program is sponsored by the Connecticut Diabetes Association and the State department of health on a statewide basis. From 1948 through 1951, 55,990 urine

tests were performed, of which 1,503 (or 2.7 percent) were found positive. These persons were referred to their physicians.

In Florida, a continuing statewide program of case finding is now in progress under sponsorship of the State board of health (4). In 1951, a mobile unit did blood sugar tests on 31,334 persons, of whom 411 with possible diabetes were referred to their physicians. Miami, Jacksonville, and Tallahassee have already been screened, and the program is now concentrating in rural areas. A followup study is also in progress. In addition to its diabetes-screening program, Florida has been maintaining a program of insulin distribution to indigent diabetic patients. In 1951, insulin worth more than \$32,000 was given free to 2,555 such patients.

In Georgia, a program of blood-testing for anemia and for abnormalities of carbohydrate metabolism was added in 1949 to the existing health test program for venereal disease and tuberculosis (5). During the past 2 years, over 300,000 persons have been screened for diabetes.

The first blood-sugar screening program in Georgia was conducted in Atlanta in 1950. Statistics for this survey show that 3.3 percent of the population examined had blood-sugar levels above normal. Confirmatory tests were not made on these people; they were referred to their private physicians for final diagnosis. One group of 6 Georgia counties tested in 1951 included 43,543 persons, of whom 55 were previously known diabetic persons, 449 were classified as suspects, and 169 had borderline blood-sugar determinations. These persons, too, were referred to their physicians.

In 1951, diabetes detection was combined with a communitywide chest X-ray survey in Contra Costa County, Calif. (6). Sponsorship of this combined screening program included State and local official and voluntary health agencies and the Public Health Service. A total of 14,681 persons who stated that they did not have diabetes were given the Wilkerson-Heftmann blood-sugar screening test. Results of this primary screening revealed 191 persons with positive tests, a rate of 1.3 percent. A more specific, second blood-sugar screening test reduced the number actually referred to private physicians

to 127. Final diagnostic reports which were received for 102 of these 127 referrals revealed 58 new cases of diabetes, 0.40 percent of the 14,681 participants. In the year following initial screening, glucose tolerance tests were performed on 32 diabetes suspects whose referrals immediately following the survey had resulted in diagnoses of either "not diabetic" or "unknown." Fifteen of them were found to have diabetic glucose tolerance curves, increasing the number of newly discovered diabetic patients to 73. This represents a discovery rate of 0.50 percent among the 14,681 participants in the survey.

These few examples of community detection programs serve to indicate the results to be achieved by such programs. In each instance, many unknowing victims of diabetes were discovered and advised to place themselves under medical care. They have thus been given the opportunity to attain their optimum health.

Education of the Public

As is true with all case-finding programs, the discovery of new cases of diabetes is not the only benefit which accrues from a diabetes detection program. This activity also provides both the occasion and the opportunity for educating the general public.

The diabetes case-finding survey affords an effective vehicle for the transmission of detailed information about the disease. It can emphasize the need for periodic health examinations as a means of preventing or forestalling many of the difficulties of long-term diabetes. Equally important, it provides the opportunity to impart to the public an understanding of the problems faced by diabetic patients in the management of their disease. Public education on diabetes can prevent the oft-repeated and tragic mistake of arresting on alcoholism charges a diabetic patient in coma or insulin shock.

The case-finding survey can serve as the basis for public support of a public health program for diabetes control. Many medical leaders believe that the concentration of attention on the problem of diabetes in the community leads to improvement in the diagnosis and treatment of the disease.

Patient Education

In no disease or pathological condition is the education of the patient a more important part of treatment than in diabetes. The patient with newly discovered diabetes faces a period of great adjustment to a new and, at first, psychologically difficult way of life. Here the public health profession can perform a great service by sharing with the physician the task of educating the patient.

Supervision by the physician is essential, but the patient himself has a major responsibility for the control of his disease. Injection of insulin, the following of a diet, a program of exercise, care of the feet, and testing of the urine are all indispensable to successful control of diabetes. Every patient, at least subconsciously, wants to do his job well, but in order for him to do so he must be given special instruction. Public health, with its long experience in health education, can help the physician by giving the diabetic patient the detailed instruction he needs to adjust to and live normally with his disease.

Leading diabetes specialists and clinics treating large numbers of diabetic patients make arrangements for special instruction through individual consultation or formal classes. Diabetes specialists also have written many manuals for the patient's instruction. This type of education, however, does not usually reach the large number of diabetic patients under the care of general practitioners. Here is a distinct opportunity for public health agencies. The wholehearted interest and enthusiasm that can be expected in such classes has been demonstrated in Jacksonville, Fla., Rochester, N. Y., and Boston, Mass.

A number of teaching aids are available for use in group or individual instruction—for example, the widely used kit, "Taking Care of Diabetes," prepared by the American Diabetes Association, the American Dietetic Association, and the Public Health Service. The kit consists of 11 film strips with sound, covering most of the problems the diabetic person faces. There are 12 wall charts, an instructor's guide, a sample set of booklets for the patient, a sample set of meal planning booklets, and a diabetes

guidebook for the physician. The kit is available for preview purposes from the Public Health Service medical directors in regional offices of the Department of Health, Education, and Welfare.

Another excellent teaching aid is the booklet, "Meal Planning With Exchange Lists," prepared by the American Diabetes Association, the American Dietetic Association, and the Public Health Service. This booklet, a recent contribution to the field, standardizes and simplifies the patient's diet. Used under the guidance of a physician, the booklet and lists allow the patient's diet to be adapted from the family menu. It is therefore easier for the patient to accept and follow the prescribed diet.

Establishing Community Programs

As has been learned from experience in the control of a disease such as tuberculosis, a detection and health education program is greatly strengthened by the cooperation of community organizations and institutions. In setting up a diabetes detection and control program, therefore, it is wise to enlist the cooperation and guidance of the local diabetes association. Encouragement of the formation of local affiliate chapters of the American Diabetes Association where none exist will pay big dividends in the successful operation of the diabetes control program.

Any control program poses problems which each community must solve for itself. In diabetes detection and control, the community must decide, for instance, whether its needs and resources indicate diabetes detection alone, or whether to add diabetes detection to a battery of tests. A community must decide, too, whether its diabetes screening program should involve the entire population or only especially vulnerable groups—persons over 40 years of age, those who are overweight, and relatives of diabetic patients. These are decisions which are best made through joint planning with the

local medical society and, if one exists, the local diabetes association.

Once a community decides on detection as part of its diabetes program, a screening technique must be selected. Examination of both blood and urine for sugar is the most reliable method of detection, but this technique is not always practical when a large-scale program is under way. For mass-testing purposes, blood-sugar analysis appears to be the most productive technique, since many suspects can be missed when urinalysis alone is used. For a relatively small expenditure of funds, special equipment for mass-testing, utilizing the blood-sugar technique, can be put into operation, and a full-scale detection program begun. Technical personnel for such an operation can be trained with relative ease, and needed supplies and materials are readily available and relatively inexpensive.

In the control of diabetes mellitus, the public health agency is both a catalyst and an auxiliary force: a catalyst which speeds up the discovery of all cases of diabetes through community action; an auxiliary force which assists the practicing physician in giving the diabetes patient the detailed information which he needs to control and live with his disease successfully.

Tuberculosis Mortality by State, 1950

FINAL 1950 tuberculosis mortality statistics (by residence) are now available from the National Office of Vital Statistics, Public Health Service, for each State and the District of Columbia. The tuberculosis death rates (all forms) ranged from a low of 6.2 per 100,000 population for Wyoming to a high of 59.6 per 100,000 for Arizona. Four States—Wyoming, Utah, Iowa and Nebraska—had less than 10 deaths per 100,000 population while 6 States—Arkansas, Tennessee, Maryland, Kentucky, New Mexico, and Arizona, and the District of Columbia—had death rates greater than 30 per 100,000.

The overall geographic pattern of tuberculosis mortality for 1950 resembled that for 1949. As shown on the map, the States having highest mortality were confined largely to the south, southwest, and east while the States with the lowest rates were generally those in the northwestern and north central parts of the country.

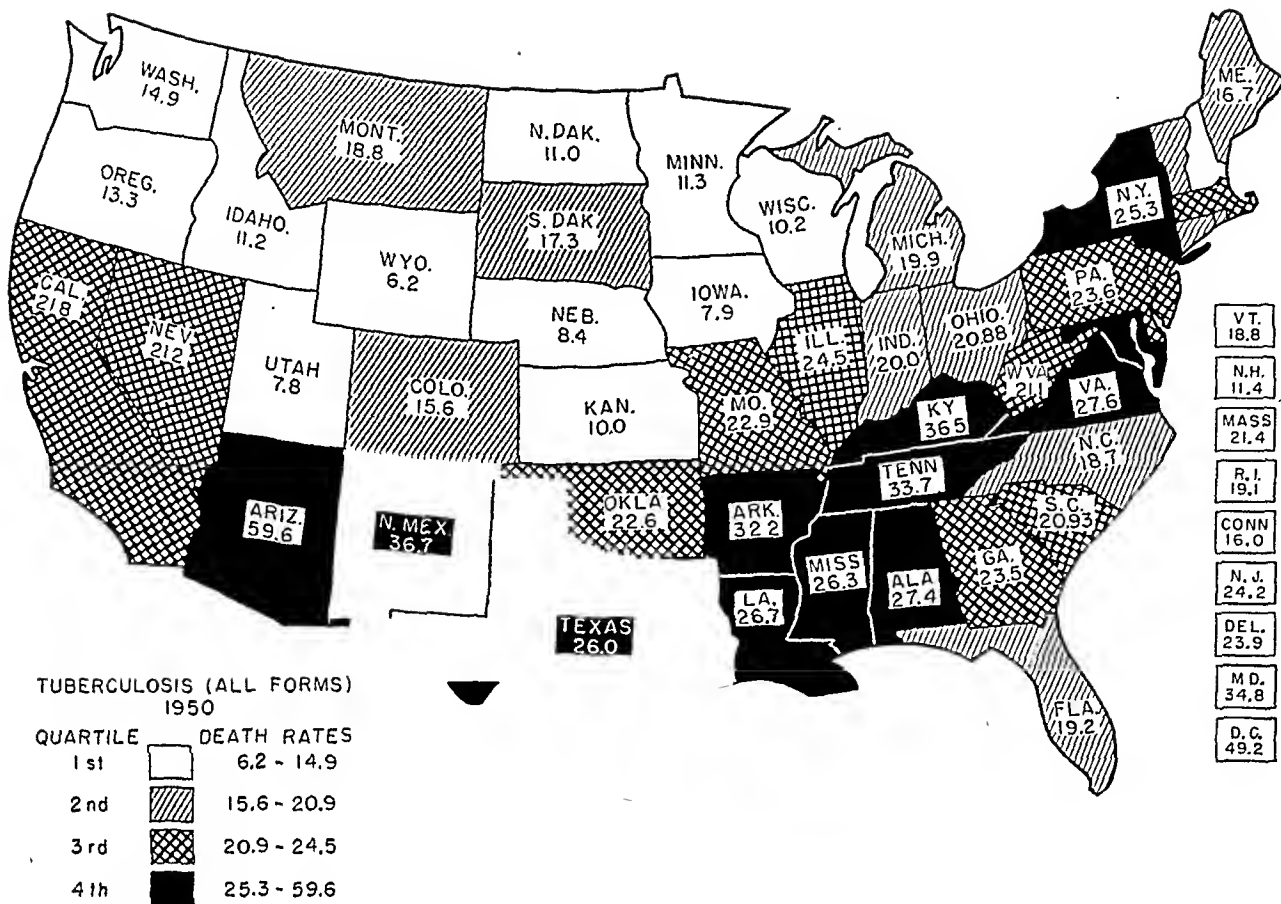

The year 1950 completes a decade of striking reductions in our tuberculosis death rate. For the continental United States, the death rate dropped from an average of 45.8 per 100,000 population for the 3-year period 1939-41 to 22.5 in 1950, a decline of 50.9 percent, whereas in the preceding decade the tuberculosis death rate declined 35.6 percent. ¹ Enumerated population Apr. 1, 1950.

trict of Columbia shared in the general decline, with 7 States—California, Colorado, Florida, Nevada, Washington, Wisconsin, and Wyoming—having declines of 60 percent or better. In Arkansas and the District of Columbia the tuberculosis death rate dropped less than 40 percent.

Although these declines are impressive, the numbers of deaths remain high for a disease whose cause and manner of prevention have been well known for over a half a century.

Furthermore, the decline in the annual num-

ber of new cases of tuberculosis reported during recent years has been slight compared with the decline in mortality. That the number of newly reported cases remains high, despite the rapid decline in death rates, underscores the fact that efforts to wipe out tuberculosis must continue to have high priority among public health problems.

This report was prepared by the Division of Chronic Disease and Tuberculosis, Public Health Service.

Public Health Service Emergency Assistance In Disaster Relief

By GORDON E. MCCALLUM, C.E., and
HARVEY F. LUDWIG, M.S.

The principal public health problems created by natural disasters are due to the breakdown of public health safeguards resulting from damage to, and failure of, certain public works and other facilities and the interruption of public services upon which present-day urban communities have become almost totally dependent. Among examples which can be cited are facilities for maintaining a safe and adequate supply of water; facilities for collecting, treating, and disposing of sewage, garbage, and other community wastes; measures for controlling and protecting against rodents and insects which transmit disease; and procedures for maintaining food and milk free from contamination. Failure of such facilities or services reverts the community to virtually primitive conditions, or worse, because the individual has largely lost his knowledge of how to obtain and purify his own water supply, how to prepare food without fuel, how to dispose of his own wastes, or how to improvise temporary shelter. Unless emergency protective measures are promptly taken, there is great hazard of large-scale epidemics of communicable diseases. The seriousness of such situations is one of the basic reasons for the unique and powerful authority of the health officer in an American State or community.

The role of the Public Health Service at times of disaster is the provision of emergency assistance to stricken areas whenever their resources become taxed to the degree that a request for

outside assistance becomes necessary. The assistance is provided through the State departments of health, as is other assistance by the Service. The Public Health Service has a long record of successfully providing such assistance: the yellow fever epidemic in Hampton, Va., in 1894 and in New Orleans in 1905; the plague outbreaks in San Francisco in 1907 and in New Orleans in 1914 and in 1920; the Mississippi River flood of 1927; the Ohio River flood of 1937; the gulf coast hurricane in 1947; the Texas City disaster of 1947; and the California encephalitis epidemic of 1952. In every instance Public Health Service assistance has simply supplemented, as required, the regular State-community public health operation, in which the community, State, and Federal health officials function as a team on all sorts of problems. Voluntary health agencies have also aided in emergency activities, with the result that over the years a close collaboration has evolved between the Public Health Service and the American National Red Cross on the handling of emergency health problems.

Policies Governing Emergency Activities

In carrying out its emergency assistance activities, the Public Health Service makes available to the States its regular resources of professional personnel, hospitals, equipment, and supplies. Under extreme conditions it can arrange additional assistance through utilization of the Reserve Corps, by which needed specialists from outside the Government can be quickly mobilized and deployed to the sites of need.

The Public Health Service also has traditionally utilized its offices to help mobilize resources from outside the regular health agencies. Through the continuing contacts of its personnel with their professional counterparts in other government agencies, military and civilian, and in voluntary and private institutions and organizations, the Public Health Service is peculiarly able to render this type of assistance.

The Kansas-Missouri Flood

The Public Health Service's participation in emergency assistance during the Kansas-Mis-

Mr. McCallum is chief of health emergency planning, Office of the Surgeon General, Public Health Service. Mr. Ludwig is consultant for sanitary engineering on the health emergency planning staff.

souri flood in the summer of 1951 was typical. When it became evident that a flood of disaster proportions was impending, the Surgeon General designated the Public Health Service regional medical director at Kansas City to supervise and coordinate Public Health Service activities. At the same time, the Communicable Disease Center dispatched necessary technicians and equipment to the flood area from various Communicable Disease Center field offices as well as from its headquarters at Atlanta. Technicians were made available also from the Public Health Service Missouri Drainage Basin Office and from miscellaneous other Public Health Service stations. During the period of the flood peak, some 70 Public Health Service specialists were assigned to duty in the flood area at the request of State health officials, including 3 medical officers, 23 sanitary engineers, 15 entomologists and other scientists, and 19 sanitarians. The work which they performed comprised emergency measures undertaken during the flood-peak period plus rehabilitation activities as the flood receded.

Emergency Measures

Of particular importance during the emergency was assistance in the restoration and maintenance of safe public water supplies. Portable water filtration and chlorinating equipment, some of which was flown into the area, was placed into use in communities where the normal water supplies had been temporarily inactivated, for example, at Ottawa, Kans., where the water supply plant was flooded out, and at Indian Creek in Johnson County, Kans., where the normal source of supply delivered from Kansas City had been interrupted. In other places, flooded pumping plants were dewatered and restored to service, and mains were disinfected with chlorine to eliminate contamination. Disinfecting chlorine compounds were furnished to residents in communities served by wells which had become flooded, for temporary use while the wells were being pumped out, sterilized, and returned to service. Arrangements were worked out with chlorine manufacturers to permit prompt shipment of extra supplies of liquid chlorine to the area had this become necessary. Special laboratory tests

were made—for example, at the Lawrence (Kans.) State Laboratory—to guide the work and to insure the continued safety of water supplies which had been subjected to contamination. Considerable work was also done in reactivating interrupted sewage disposal works, including pumping plants, to prevent further contamination of water supplies.

Other work accomplished during the emergency period included assistance in the maintenance of safe food and milk supplies at evacuation centers, furnishing and distributing medical supplies, including vaccines, and careful epidemiological surveillance to detect possible outbreaks of epidemics.

Rehabilitation Activities

The recession of the flood waters increased rather than decreased the scope of the environmental sanitation activities. A large number of Public Health Service personnel worked over a prolonged period in controlling insect breeding and nuisances. This work required the use of much insecticide spraying equipment and large supplies of DDT, chlordan, oil, and other insecticides, some of which were delivered to the area by air transport. Initial emphasis was placed on fly control to prevent the possible spread of diseases such as typhoid and dysentery; and later emphasis, on mosquito control to assist local authorities in preventing an abnormal incidence of potential disease vectors. Entomological experts supervised the work, after making on-the-spot surveys to determine what control measures would be most effective.

Another important problem facing local health authorities was the disposal of approximately 12,000 dead animals. This was accomplished principally by hauling the animals by truck to landfills for disposal by burial. Inspection of milk and food supplies was expanded to check all sources which had been subjected to contamination or spoilage, and to release only those products safe for consumption. Special measures were also taken to reinforce the normal rodent control programs of the flooded communities. Special checks of rat populations were made and rat poisons applied in those zones where rat populations were increasing because of migration or extraordinary exposure of food supplies. The importance of

these various continuing activities is indicated by the fact that 1 month after the flood peak several of the Public Health Service technicians were still on the job.

No abnormal incidence of any communicable disease was reported for any community in the area.

Legislative Authority

Authority for Public Health Service activities in assisting States at times of emergency is included in its authority for assisting States generally. Emergency assistance is customarily provided through the loan of specifically qualified personnel on State request under section 214 of the Public Health Service Act (Public Law 410, 78th Cong.).

More generally, section 311 of this act directs the Surgeon General to assist States and their political subdivisions in the prevention and suppression of communicable diseases and in the enforcement of local health regulations; also, the Interstate Quarantine Regulations of the Service, issued under section 361 of the act, authorize the Surgeon General to take special measures to prevent the interstate spread of the more important communicable diseases.

In the event of emergency or disaster, the President, under section 216 of the Public Health Service Act or under the Disaster Relief Act of 1950 (Public Law 875, 81st Cong.) may direct the utilization of the specialized personnel, equipment, and other facilities of the Service.

Financing Emergency Assistance

The Public Health Service has available, in the amount of \$40,000 annually, a special disaster and epidemic control fund, which is administered within the Communicable Disease Center of the Public Health Service. In years when one or more major disasters occur, especially disasters such as floods which create relatively great public health problems, this sum has not been adequate to meet the needs. In every instance, however, the Public Health Service has responded to requests from States to furnish at least the bare minimum of assistance necessary to prevent epidemics. Whenever necessary the Public Health Service has, with proper authority, utilized resources from regular operating programs—the emergency needs of States being given special priority in the sense that the prevention of mass epidemics is a Service function of the very highest importance.

Enactment of the Disaster Relief Act makes it possible for additional funds to be made available to finance Public Health Service emergency operations. The availability of such funds constitutes a kind of "insurance" and should make possible the undertaking of all essential emergency relief operations with a minimum of apprehension as to effects on regular program operations. And most important, the availability of funds through this act, in the form of grants to stricken communities will expedite their own recovery activities; thus the conditions which create major health hazards may be more quickly corrected.

A Preventive Medicine Screening Program in a Venereal Disease Clinic

By GERALD J. GRUMAN, M.D.

Many patients seen at the State of Kentucky Prevention and Control Center are discovered to have other health problems besides the venereal disease for which they were referred. In the past these patients were dealt with on an informal basis. However, the staff lately has attempted to organize this side of its work into a formal program of preventive medicine. The program costs nothing extra.

Each patient (other than those diagnosed as having gonorrhea) is given a thorough physical examination. This includes: funduscopic examination; breast, pelvic, and rectal examinations in all women; and rectal examination in all men over forty. Each patient presenting an emotional problem is given a 30-minute interview when it is possible. If this procedure reveals the need for diagnosis or treatment of nonvenereal conditions, the patient is referred to a public or private facility. The patient is given a sealed letter describing his venereal disease status and reasons for referral.

Frequently we discover neglected nonvenereal problems in gonorrhea patients. With our present facilities it is impracticable to do a complete physical examination on each gonorrhea patient. Therefore, our data on gonorrhea patients are not included in this report.

A study of records for 2 months reveals that 259 nongonorrhea patients have been seen in the clinic and have received the physical examination described above. The examination of these 259 patients revealed the presence of a neglected nonvenereal condition in 50 patients (19 percent).

The suspicion of cancer in most cases was aroused by the presence of nodules or masses in the breast, prostate, cervix, uterus, or ab-

domen. The urologic conditions were mostly nongonorrheal prostatitis. The psychiatric problems were related to sexual impotence, homosexuality, or syphilophobia. The skin conditions were venereal warts, scabies, and contact dermatitis. The eye conditions were refractive error and pterygium. The gynecologic conditions were prolapse of the uterus and monilial vaginitis. The neurological conditions were polyneuritis and epilepsy. The vocational rehabilitation problems were related to blindness and neuromuscular disability following trauma. The other conditions included precocious puberty, peptic ulcer, respiratory infections, and perineal abscesses.

<i>Nonvenereal conditions</i>	<i>Patients</i>
Suspicion of cancer-----	19
Urologic-----	6
Psychiatric -----	5
Skin -----	4
Eye -----	2
Gynecologic -----	2
Neurological-----	2
Vocational rehabilitation problems-----	2
Others -----	8

By systematizing the nonvenereal aspects of our work, we have been enabled to see a definite pattern. Certain gaps are revealed which suggest amendments to the original plan. For example, with very little trouble, we could give dental referral slips to patients with caries. (Nearly 100 percent of our patients reveal signs of poor dental hygiene.) We could refer many youngsters for circumcision. Our vocational rehabilitation work readily could be expanded.

The diagnosis and treatment of venereal disease is being done more and more by small prevention and control centers like ours. The results of our program give an interesting indication of what can be accomplished by such a small staff dealing with patients on an outpatient basis only. We do not have any laboratory facilities for X-rays or urinalyses. Yet, a thorough history and physical examination of 259 patients were enough to reveal to us more nonvenereal health problems than we could possibly handle.

The records reveal another interesting situation: Of the 50 patients described above, 40 were referred to private practitioners of their own choice, and 10 were referred to public facilities. Thus 16 percent of all the patients ex-

Dr. Gruman is a commissioned officer of the Public Health Service. He is now stationed at the State of Kentucky Prevention and Control Center, Louisville.

amined in our public clinic were referred to private practitioners because of nonvenereal conditions.

The reporting of these patients with our letters of referral is creating an increased feeling of good will among the private practitioners towards the venereal disease clinic. Also, the appearance of the patient with his letter is a means of acquainting the private physicians

and the community health and welfare personnel with the fact that a venereal disease clinic exists and performs various important functions. Thus, by carrying on a preventive medicine screening program in a systematic manner, a specialized clinic is helping to create that organic network of interrelated services and that climate of good will and cooperation so necessary to the community's public health system.

Dr. Candau Appointed WHO Director-General

Dr. M. G. Candau of Rio de Janeiro, Brazil, was appointed Director-General of the World Health Organization by the Sixth World Health Assembly on May 11, 1953. Dr. Candau, who will serve for a 5-year term beginning July 22, 1953, succeeds Dr. Brock Chisholm. Dr. Candau is presently deputy director of the Pan American Sanitary Bureau, Washington, D. C., the regional office for the Americas of the World Health Organization.

The Sixth World Health Assembly convened at Geneva, Switzerland, on May 5, 1953. The World Health Assembly is the supreme legislative body of the World Health Organization and meets once each year. A 16-member delegation represented the United States at the Assembly. Surgeon General Leonard A. Scheele of the Public Health Service was the chief delegate and chairman of the United States delegation. Other members included—

Delegates: Leonard W. Larson, M.D., member, Board of Trustees, American Medical Association, Bismarck, N. Dak., and Franklin D. Murphy, M.D., chancellor, University of Kansas.

Alternate delegates: Henry van Zile Hyde, M.D., and Frederick J. Brady, M.D., respectively chief and international health representative of the Division of International Health, Bureau of State Services, Public Health Service; also, Howard B. Calderwood, specialist in international organization, Office of United Nations Economic and Social Affairs, Department of State.

Congressional advisers: Congressman Homer D. Angell of Portland, Oreg., and Congressman Wayne L. Hays of Flushing, Ohio.

Advisers: Knud Stowman, Ph.D., international health representative, Division of International Health, Bureau of State Services, Public Health Service; Robert T. Stormont, M.D., secretary, Council on Pharmacy and Chemistry, American Medical Association, Chicago; Carl N. Neupert, M.D., State health officer, Wisconsin State Board of Health, Madison; Col. Thomas F. Whayne, MC, USA, chief of preventive medicine, Department of the Army; Ruth Sleeper, director, School of Nursing and Nursing Services, Massachusetts General Hospital, Boston; and Carol C. Laise, Division of International Administration, Department of State.

Henry F. Nichol was secretary and Mason A. LaSelle was administrative officer of the delegation. Both are with the Resident United States Delegation for International Organization Affairs at Geneva.

Oral Manifestations of Occupational Origin

The purpose of this compilation, the foreword states, is to bring together information relating to oral conditions which are associated with occupations, to make such material more readily available to dentists and other interested persons or groups.

The articles are arranged according to category of exposure, namely, acids, bacteria, dusts, gases, inorganic substances, metals, organic compounds, and physical factors. Articles referring to several types of exposure are classified under "General Review." Occupational cancer has been placed in a separate category. The types of exposure within each category are listed alphabetically. In those instances where more than one article is presented for a specific exposure, the listing is in reverse chronological order with the more recent articles appearing first. Numbers following listed headings refer to item numbers, which run consecutively throughout the publication. An author index follows the abstracts.

Walters, F. J., Fridl, J. W., Nelson, R. L., and Trost, J. W.: *Oral Manifestations of Occupational Origin—An Annotated Bibliography*. Public Health Bibliography Series No. 7 (Public Health Service Publication No. 228). 41 pages. 20 cents.

Guide to Health Organization in the United States

A panoramic view of the entire health structure of our Nation is contained in this pamphlet, the preface states. The authors point to the contributions of Federal, State, and local official and voluntary agencies, and of private physicians, dentists, and nurses. The salient functions of the many agencies which

give health services in the United States are brought together in a simple brief form.

The pamphlet, first issued in 1946 and reprinted in 1948 and 1950, as "Guide to Health Organization in the United States—Miscellaneous Publication No. 35," has been used widely in orienting professional public health workers, visitors from other countries, and American students to the multiple systems of health service. It has also proved to be a concise and readable source of information for the general public.

Because of the substantial changes which have taken place during the past 5 years—both in content and in organization of public health services—the "Guide" has been revised in this second edition to reflect the public health picture of 1951. Substantive changes have been restricted to those necessary to bring the material up to date and those indicated by experience in using the first edition. To guide those who wish a more detailed and comprehensive grasp of the organization and administration of health services, an extensive bibliography is appended.

National Heart Institute

Text, charts, statistics, and photographs tell the story of the programs and work of the National Heart Institute which was created under the National Heart Act of June 16, 1948. Twin goals of the heart program are: (1) to find new and better ways of preventing, diagnosing, treating, and curing heart disease, and (2) to see that what is already known (and what is discovered by research) is fully applied to reduce death, disability, and suffering caused by heart disease. Funds are appropriated by the Congress to carry out the work of the National

Heart Institute and are allocated for National Heart Institute research; research grants; research fellowships; clinical traineeships; teaching grants; control grants to States; technical assistance in control; review and approval of grants; and program direction and administration.

The National Heart Institute, a part of the National Institutes of Health, Public Health Service, conducts an integrated program of research in its own laboratories and in cooperating institutions. The grants for medical research are made to universities and hospitals all over the country; to individual scientists to carry out important heart disease research projects; for construction of additional vitally needed research facilities; and for specialized training in cardiovascular diseases. The research fellowships program helps to relieve the scarcity of well-trained scientists in the heart disease field; and clinical traineeships are available to doctors under 40 years of age who have completed a year's general internship and an additional year of training and experience. Teaching grants make it possible for medical schools to coordinate and improve instruction in subjects on heart disease, and technical assistance provided through the heart section of the Division of Chronic Disease and Tuberculosis of the Public Health Service aids the States in technical matters relating to heart disease control measures. Pilot studies are conducted to determine the best methods and techniques for developing and operating a community heart program. These are actual field demonstrations in heart disease control, carried out in cooperation with State and local health departments and medical societies.

The inside front cover of this booklet quotes the purpose of the National Heart Act, and the inside back cover shows a chart of the structure of the Public Health Service heart program.

A Draft Act Governing Hospitalization Of the Mentally Ill

From time to time, State officials, lawyers, judges, and members of the medical profession have suggested the need for a model statute incorporating widely accepted concepts of legal and medical procedure for hospitalizing the mentally ill. In response to this need, and in view of the interest shown by the State governors at their annual conferences, the National Advisory Mental Health Council requested the Federal Security Agency to prepare a draft of such legislation. A working committee, staffed by medical and legal representatives of the National Institute of Mental Health, St. Elizabeths Hospital, and the Office of General Counsel, assisted by a special consultant, formulated the work that is known as *A Draft Act Governing the Hospitalization of the Mentally Ill*. Some 40 outside medical and legal authorities were consulted for their views during the planning period. In September 1950, a draft of the suggested legislation was transmitted to all of the State governors.

In brief, the legislation proceeds on the philosophy that the mentally ill are sick persons and that society, in depriving them of their freedom, is obligated to assure that procedures for their hospitalization, particularly those individuals whose condition renders them incapable of making decisions, should be surrounded by equitable safeguards. Under the provisions of the suggested legislation, the mentally ill would be spared public humiliation, degrading or emotionally harmful treatment, and their commitment would be free of any penal connotations. Restrictive obstacles to prompt medical care would be removed through provisions in the legislation for permitting voluntary admission upon medical certification.

In September 1952, certain portions of the text, and, in some cases, the terminology, were revised to strengthen the original concepts of the legislation and to clarify the language where it might be ambiguously interpreted. The revision was completed after intensive review and discussion of the proposed changes by the original working committee. In this work, the committee exchanged views with medical and legal authorities of the National Association for Mental Health, Inc., a voluntary, non-profit organization. Two very important changes in the revised edition are the clarification of the basic criteria for identifying individuals in need of hospitalization and procedures covering the admission of individuals in emergency medical situations. Among the other revisions are several that emphasize the importance of assisting the patient to maintain his morale during hospitalization and subsequent convalescence.

A Draft Act Governing Hospitalization of the Mentally Ill. (Public Health Service Publication No. 51). Revised 1952. 36 pages. 15 cents.

Directory of Full-Time Local Health Units—1952

Revised as of July 1952, this directory contains a listing of full-time health units serving local areas, together with the name of the health officer of each unit or other designated administrative head, and headquarters location.

A full-time health unit is one officially organized to provide medical, nursing, and sanitation public health services during the regularly scheduled work week of the governmental unit to which it is attached and which is under the direction of a full-time health officer or other designated full-time administrative head.

The information is arranged alphabetically by State and by type of health organization: local units (county, city, and local district) and

State districts (either rendering actual local services or providing supervisory and advisory services).

The number of full-time units rendering local health service with the number of counties served, and the full-time units with the position of health officer vacant or temporarily filled by a neighboring health officer are summarized in the appendixes.

Directory of Full-Time Local Health Units—1952. (Public Health Service Publication No. 118) 1952 revision. 63 pages. 25 cents.

Help Fight Pollution Now

Designed for display at State fairs, conventions, conferences, libraries, and other places, this five-color 3- by 4-foot poster stresses the necessity of the abatement of water pollution and the conservation of our water resources for home use, industry, agriculture, and recreation. It also has been used as the central panel of a larger exhibit which points out the responsibility of the community and of industry in preventing water pollution (see the November 1952 issue, *Public Health Reports*, p. 1087). The poster shows in one corner a desert scene with the whitened bones of an animal beside a dry water hole. This picture bears the legend, "Polluted water is almost as bad as no water." The central portion pictures a stream being polluted by industrial waste from factories on its banks. A banner across the center states, "Clean up water for . . ." and points to a series of five pictures showing water uses. The words, "Help Fight Pollution Now" appear across the bottom of the poster.

Achievements in Public Health

July 1, 1951-June 30, 1952

PROGRESS in the field of public health during the fiscal year 1952, as reflected through the activities of the Public Health Service, is delineated in some detail in the eightieth Annual Report of the Service. Continued success in controlling acute communicable diseases, the opening of new fields of knowledge through research, expansion of the Nation's network of hospitals, and intensification and broadening of State and local health activities are salient among the accomplishments noted. The Public Health Service, in partnership with State and local health departments and in cooperation with other health agencies and organizations, has contributed much to these, as well as many other, achievements of the year.

Health Status

In 1951, for the fourth consecutive year, the death rate was below 10 per 1,000 population. Death rates from infectious diseases have continued the steep descent which began in 1900. The tuberculosis death rate was at a record low of 19 per 100,000 population; the rate for syphilis was 5 per 100,000; and the combined death rate for the principal communicable diseases of childhood was less than 2 per 100,000. Chronic diseases, first claiming their place as chief causes of death in 1914, today represent the greatest challenge in health. Adequate prevention of these diseases will require intensive efforts of all members of the health professions.

Medical Research

The immediate program of expansion in organization, in facilities, and in scope of activity

which began in 1948 for the National Institutes of Health, the center of the Service's medical research activities, neared completion in fiscal 1952. A milestone in this record of progress will be the opening of the Public Health Service Clinical Center in 1953. The Clinical Center will provide unique facilities for the medical practice-medical research-public health team to coordinate the study of chronic and crippling diseases.

The past year has also witnessed valuable contributions to medicine and public health by scientists in all seven of the Institutes as well as by many nongovernmental scientists in universities, hospitals, and other research institutions who have been aided through research grants and fellowships. The Annual Report describes a number of the research findings of the year.

Public Health Resources

With conservation a basic principle, the Public Health Service is contributing to the expansion of the Nation's health resources and at the same time providing important advisory and technical assistance in the endeavors of our health organizations to make maximum use of existing resources in personnel, facilities, and materials.

Acting as claimant for the Controlled Materials Plan, which went into effect July 7, 1951, the Service played an important part in sustaining health facility construction. Facilities estimated at \$781,000,000 were added to the Nation's health resources in fiscal 1952, setting a new high mark in civilian construction. Through the Public Health Service, Federal funds for loans or grants were made available for construction of various community health

facilities in critical defense housing areas and for hospital construction throughout the Nation. The Service also provided information and consultation on many problems of hospital operation, health manpower utilization, and hygiene of housing. Studies of the prevalence and severity of disabling illness were undertaken as part of the Service's contributions to the conservation of manpower resources of the Nation.

Health Services

Helping States and communities discharge their responsibilities for the maintenance and improvement of health is one of the major jobs of the Public Health Service. Centered in the Bureau of State Services, assistance includes both grants of funds and direct Federal technical services. These include collection and analysis of health data, consultation on specific problems, and field studies and demonstrations to develop and test new methods.

Grant-in-aid payments made in fiscal 1952 amounted to \$31,626,412. Technical, investigative, and consultative assistance in the form of surveys and studies, case-finding projects, laboratory services, training services, and program planning and development was provided in the fields of health education, public health nursing, environmental health, occupational health, disease prevention control, and dental health.

The Public Health Service also provides, as directed by law, medical and hospital care for specific groups, including merchant seamen. Over 500,000 beneficiaries received treatment

during the year at the 22 hospitals, 19 outpatient clinics, and more than 100 outpatient offices of the Service. In addition, the Service assigns health personnel to other Federal agencies to aid them in carrying out their health programs: Office of Vocational Rehabilitation, Bureau of Employees' Compensation, Bureau of Prisons, United States Coast Guard, Maritime Administration, Bureau of Indian Affairs, and the Department of State.

World Health

By the assignment of public health experts to the technical assistance missions sponsored by the Mutual Security Agency and the Technical Cooperation Administration, the Public Health Service plays a leading role in developing and operating health programs of these missions. During 1952, such programs were in operation in 16 countries—Burma, Formosa, Greece, Indochina, Indonesia, Philippines, Thailand, Turkey, India, Iran, Iraq, Israel, Jordan, Lebanon, Liberia, and Libya—and plans were developed for establishment of programs in 14 other countries. The Service also continued to serve as official liaison with the World Health Organization and the Pan-American Sanitary Bureau. The Surgeon General was president of the Fifth World Health Assembly, which met in May 1952.

Rabies

A leaflet on rabies warns that this disease is widespread among animals in the United States and in recent years has been on the increase. Rabies affects the nervous system, including the brain and

spinal cord, of animals and man, and once developed, it is always fatal.

The virus causing rabies may be transmitted by the bite of an infected animal if the saliva of the infected animal comes in contact with an open wound. All warm-blooded animals may contract the disease and spread it. Recently foxes have showed an increase in rabies incidence. Dog bites account for 90 percent of the human cases of rabies in the United States.

The leaflet describes two types of rabies, symptoms of each type, incubation periods, and the progression of the disease in humans and in animals. It tells what to do with a dog suspected of being rabid. It offers pointers for preventing rabies and stresses them because the disease cannot be cured.

Rabies. Health Information Series No. 30 (Public Health Service Publication No. 97) 1952. 2-fold leaflet. \$1.50 per 100.

2d Conference of Mental Hospital Administrators and Statisticians—Proceedings

To assess accomplishments of activities of State mental hospital statistics, comparable statistics on patients treated in such systems are needed. At present, the kinds of data produced by the different States lack uniformity and comparability.

At the Second Annual Conference of Mental Hospital Administrators and Statisticians, called by the National Institute of Mental Health of the Public Health Service on February 25-27, 1952, some of the many problems of standardization of reporting which were discussed dealt with definitions, nomenclature, and tabulations. Conferees represented the 11 States grouped into a model reporting area for mental hospital statistics at a first conference in 1951. These States are: Arkansas, California, Illinois, Louisiana, Michigan, Nebraska, New Jersey, New York, Ohio, Pennsylvania, and Virginia.

In mental hospital systems there is lack of uniformity in definition of terms, such as first admission, resident patient, transfer, and so forth, used to describe the movement of patients into and out of the hospital. For example, in some States, first admissions relate to a particular State hospital; in other States to a particular State hospital system; in still others to any State hospital system; and in the remainder to treatment for mental disorder anywhere.

Comparable data are not always available in different States even on such basic items as length of hospitalization of discharged mental patients by diagnosis, age, sex, and other factors. Methods used for analyzing data have not always been appropriate to the long-term nature of mental illness. These and other difficulties have made it impossible, according to Dr. Morton Kramer, chief of the biometrics branch of the National Institute of Mental Health and chairman of the 1952 conference, to demonstrate satisfactorily the accomplishments or failures in treating the mentally ill.

In a foreword to the published proceedings of the second conference, Dr. R. H. Felix, director of the National Institute of Mental Health, expressed the hope that the progressive thinking of the 11 States will stimulate other States to develop and expand their statistical offices and to collect and tabulate data in a uniform manner so as to meet the standards for inclusion in the model reporting area. At the conference, it was generally agreed that to meet the minimum requirements for inclusion, a State should have a central statistical system supervised by a professional statistician, should agree to the definitions adopted by the model area, and should agree to produce annually the minimum number and type of tables agreed upon by the model area States.

Conferees agreed on definitions for first admission and resident population. They also agreed to exchange ideas concerning needed data; to permit a review of their States' programs of statistics and research in mental hospitals; to develop an effective system of statistical reporting to the National Institute of Mental Health; to continue to form the nucleus of a model area; and to urge the extension of uniform reporting methods to all States.

Included in the 13 appendices to the proceedings are tables comparing data on first admissions in New York State in 1914 with 7 other States in 1948; a study on services and treatment facilities for mental patients in general hospitals; a study on discharges from the psychiatric division at Bellevue Hospital, New York City; a plan for a census of patients in mental institutions on a cyclical basis; a paper on standard control groups for the evaluation of therapy; and another on suggested cohort studies of first admissions.

Salaries of State Public Health Workers

This study, the sixth of a series of annual studies of salaries paid to selected classifications of personnel employed by State health departments, includes full-time professional personnel—medical, nursing, sanitary engineering, sanitation, nutrition, health education, statistical, laboratory, business management, dental, and veterinary. The data were obtained from State health department payrolls for August 1952.

Information on salaries paid State health officers, five selected nonmedical program directors, and personnel in the occupational groups listed above is presented by bar graphs. For the convenience of those desiring more detailed information, tables showing salary distribution by States are included for all of these occupational groups except business management officers, health educators, nutritionists, and statisticians.

General salary increases between August 1950, August 1951, and August 1952 are shown for nine occupational groups. For these nine groups the average percentage increase in the lower limits of the salary intervals in which the median appeared was approximately 6.5 percent. Two occupational groups, dentists and veterinarians, were added to the study this year. The salary intervals within the median salaries which appeared in 1950, 1951, and 1952, and the percentage changes in the lower limits of the salary intervals in which the median appeared in 1947, 1948, 1949, 1950, 1951, and 1952 are shown by tabular listings.

Diphtheria

Diphtheria, a dangerous disease, can be prevented. Knowing something of what diphtheria is like will help one to understand why it is important to guard against it. This leaflet tells of diphtheria epidemics as late as the 1880's, and of the protection of inoculation which has resulted in far fewer deaths from this disease now. What diphtheria is like, how the germs behave, how the disease gets around, and how to stop it before it starts are explained. Emphasis is placed on immunization for every baby and when to call the doctor.

• • •

Diphtheria. Health Information Series No. 37 (Public Health Service Publication No. 60) 1953. 2-fold leaflet. \$1.50 per 100.

Louse Infestation

Lack of personal cleanliness is one of the most common predisposing causes of infestation with the three varieties of body lice discussed in this health information leaflet. The leaflet describes the head louse, the body louse, and the pubic or crab louse, and the manner in which their presence is detected. Consultation with a physician is advised for proper treatment, and scrupulous care and cleanliness for the prevention of the recurrence of the lice.

• • •

Louse Infestation. Health Information Series No. 26 (Public Health Service Publication No. 103). Revised 1952. 1-fold leaflet. 5 cents; \$1.50 per 100.

Hypertension

Only a doctor can tell by physical examination whether you have high blood pressure, and whether it's serious enough to need attention. People who worry too much over unsolved problem are often susceptible. Heredity is probably a factor, and the condition occurs most often

in persons between 30 and 50 years of age. High blood pressure, or hypertension, is a common disorder which shows up in the heart and blood vessels. In itself, high blood pressure is not a disease, but a sign of something wrong. If blood pressure remains consistently high for a long period of time, however, it can result in serious damage to the heart, the kidneys, and other organs of the body.

There are undoubtedly millions of persons in the United States who have high blood pressure and don't know they have it. Headaches and dizziness may be symptoms, but can be symptoms of other conditions, or there may be no symptoms at all. One can have high blood pressure without being ill or in danger of a sudden breakdown of the heart or arteries.

These statements are made with others in this health information leaflet to explain to the person who may have high or low blood pressure the need to get under a doctor's care and follow a few simple rules for moderate living so that he may be able to continue to work and enjoy life.

• • •

Hypertension. Health Information Series No. 69. (Public Health Service Publication No. 146) 1952. 2-fold leaflet. \$1.25 per 100 copies.

Trichinosis

The major emphasis in this health information leaflet is on the fact that trichinosis, caused by eating raw or insufficiently cooked pork, is preventable. Pork is a wholesome, flavorful food, and there is no reason why it should not be a part of the diet, but it must be cooked thoroughly.

The leaflet explains how long meat should be cooked and how it can be tested to see if it is done. Some processed meats are treated to kill the trichinae, and the reader is advised to look for the stamp which indicates that the meat has been federally inspected and passed. Another means of prevention which is discussed is the cooking of garbage that is fed to hogs.

The leaflet also contains information on the way in which the trichinae affect the body, the symptoms of the disease, and the forms of treatment.

• • •

Trichinosis. Health Information Series, No. 47 (Public Health Service Publication No. 101) reprinted 1952. 2-fold leaflet. 5 cents; \$1.00 per 100 copies.

Tularemia

Bacterium tularensis produces in certain infected animals peculiar spots in the spleen, liver, and bone marrow, with enlargement of and abscess formation in the lymph glands. This disease, tularemia, man acquires through the handling of dead animals, or by eating the undercooked flesh of an infected animal, or by being bitten by an insect which has previously fed on a diseased animal. The commonest history of a human case is that of the person who has handled the carcass of an infected rabbit. This leaflet states that prevention of tularemia is almost entirely a matter of personal precaution and tells how to take such precautions.

The mode of infection is briefly described, as is the incubation period of the disease. Diagnosis can be aided by certain tests, the leaflet states. Streptomycin has been employed and found to be of great value in the treatment of tularemia when used early in the course of the disease.

• • •

Tularemia. Health Information Series No. 44 (Public Health Service Publication No. 135) 1-fold leaflet. \$1.25 per 100.

Tuberculosis Cases Known To Health Departments

By ROBERT J. ANDERSON, M.D., HERBERT I. SAUER,
and ROGER L. ROBERTSON, M.A.

HOW MANY tuberculosis cases are known to health departments in the United States? Are they receiving needed public health supervision; that is, are they receiving periodic medical examinations, laboratory services, and the instruction necessary to prevent further spread of tuberculosis?

Ideally, one of the best measures of the tuberculosis problem in the United States lies in true prevalence, that is, the total number of cases at a given time. For it is these cases which, in the aggregate, represent the actual and potential reservoir of infection and which require case-finding facilities, public health supervision, and medical care in order to prevent or alleviate disability and economic loss from the disease.

In the absence of data on true prevalence, public health workers have for many years attempted to measure the size of the tuberculosis problem and the progress made against it in terms of mortality—the number of tuberculosis deaths occurring annually. Declining tuberculosis mortality rates, however, are probably a poor index of changes in prevalence, since they partially reflect declining case fatality rates resulting from earlier and more effective case finding and treatment. Declining case fatality rates and a continuing high level of morbidity reporting tend, in turn, to maintain known prev-

alence at a high level, since cases of a type which previously terminated in early death now go on, after an extended period of treatment, to an arrested state. These cases, with the ever present opportunity for reactivation, are thus actually present in our population for longer periods than previously.

The true prevalence of tuberculosis can only be estimated. Until recent years, there have been very few counts of the number of known cases, even for large local health departments. Now, with increased use of tuberculosis case registers in various parts of the country, more information is becoming available regarding known cases and their supervision.

In the past, most data on tuberculosis morbidity have been on cases newly reported during a given year. This present study, however, deals with known prevalence—the total number of known tuberculosis cases as of a specified date—and with the public health supervision of those cases. By definition, known prevalence includes all cases which are considered by the health department at the date of tabulation to be significant for supervision, even though these cases may have been first reported as new cases many years previously. This includes not only active tuberculosis cases but also those with activity undetermined, arrested tuberculosis, or inactive tuberculosis which the health department considers significant for supervision. Known prevalence should not be confused with true prevalence, since the latter includes also estimates of the number of unknown cases in a specified area.

Dr. Anderson is chief of the Division of Chronic Disease and Tuberculosis, Public Health Service. Mr. Sauer and Mr. Robertson are statisticians in the division.

Recent estimates of prevalence which have appeared elsewhere have been based in part on the preliminary summaries of data presented in this report (1, 2).

Sources of Data

Reports used in this study bear various dates between January 1949 and January 1953. Included are reports from 19 entire States (except for 4 local health departments whose reports are tabulated separately because their tuberculosis control programs are administratively separate from the States'), districts in 2 States consisting of a number of counties in each, and 47 local health departments. Thus there is included a total of 72 areas presenting data on one or more aspects of the problem here discussed. These areas account for approximately 50 percent of all tuberculosis deaths and 46 percent of the total population in the United States. In all, 38 States and the District of Columbia are included either wholly or in part.

Statistical reports from a specific administrative level (State, district, or local) were included in this study only when there was known to be a definite policy and practice at that level of obtaining information on the supervision of cases and their current status. Generally, the reports used were prepared on the tuberculosis case register summary report, for the most part in accordance with recommended instructions (3). However, since these reports were prepared by individuals in many different health departments, there were undoubtedly some variations in the procedures used. In summarizing these reports, every attempt has been made to include from each only those data which were reported in accordance with accepted practice or which could be made comparable by a minimum of editing. It is for this reason that there is variation in the number of areas reporting each type of information tabulated.

Of the 72 areas for which data were available, 22 are places in which communitywide chest X-ray surveys have been conducted in cooperation with the Public Health Service. While the remaining 50 areas have had some X-ray case-finding activities, the proportions of the populations X-rayed have generally been much

smaller. Comparisons between the areas with more intensive case finding and areas with less intensive case finding are presented throughout this paper. It seems likely that the differences noted reflect the effects of the X-ray surveys and the intensification of tuberculosis control efforts resulting therefrom. However, there is no absolute assurance of this, since the surveyed areas are not statistically representative of all areas for which data are available. Nevertheless, certain comparisons may be made which appear meaningful. For example, comparisons of known prevalence rates in surveyed areas with those in nonsurveyed areas probably are sound enough to permit some conclusions as to the effects of communitywide surveys.

Known Prevalence

In the 72 areas included in this study, there were 233,028 tuberculosis cases known to health departments and considered by the health departments to be significant for supervision, a rate of 339 known significant cases per 100,000 population (table 1). As is also indicated in

Table 1. Known tuberculosis cases and case rates in selected groups of health department areas

[United States, January 1949 through January 1953]

	Number of health department areas with data available	Population included in group of areas (as of Apr. 1, 1950)	Cases	Cases per 100,000 population
Total known cases-----	72	68,762,021	233,028	339
Survey areas----	22	12,239,785	57,973	474
Other areas----	50	56,522,236	175,055	310
Active cases----	56	45,343,259	72,185	159
Survey areas----	22	12,239,785	21,725	178
Other areas----	34	33,103,474	50,460	152
Positive sputum cases at home----	49	45,504,340	11,760	26
Survey areas----	16	7,232,554	2,569	36
Other areas----	33	38,271,786	9,191	24
Hospitalized cases plus positive sputum cases at home----	47	42,929,325	36,773	86
Survey areas----	16	7,232,554	8,677	120
Other areas----	31	35,696,771	28,096	79

table 1, the areas which have had community-wide chest X-ray surveys had much higher rates of known significant tuberculosis (474 per 100,000 population) than did other areas (310 per 100,000 population). For individual areas the rates ranged from 50 to 1,800 cases per 100,000 population.

Aside from the true prevalence of tuberculosis in each area, factors which appear to influence the number of known significant cases are: (a) the extent and effectiveness of case finding and reporting, (b) the extent of efforts to maintain supervision of known significant cases, and (c) the promptness with which cases are dismissed. Some health departments, for example, dismiss a case merely because it is reported as lost, while others make a thorough search for the patient before discharging him as lost. Some health departments, too, find it administratively desirable to dismiss cases from the central register as soon as they are classified as inactive, while others may continue supervision until the cases have been arrested or inactive for 5 years.

Active Cases and Hospitalization

In 56 areas with information available regarding activity status, there were 72,185 active tuberculosis cases known to health authorities, or approximately 159 per 100,000 population. Among these areas there was a range from 30 to 1,227 known active cases per 100,000 population (fig. 1). Variations in these rates no doubt parallel variation in the true prevalence of tuberculosis more closely than do the rates for total cases known, since health department policies for keeping active cases in their case registers are more nearly uniform than those governing total significant cases (which include arrested cases).

Known prevalence of active tuberculosis is also influenced, however, by the extent and effectiveness of case finding and case holding. This is suggested by the fact that those areas which have had communitywide chest X-ray surveys showed 178 known active cases per 100,000 population, in comparison with a rate of 152 in the nonsurvey areas. Before the surveys, survey areas had rates similar to those of nonsurvey areas.

Figure 1. Known active tuberculosis cases per 100,000 population, 56 health department areas in the United States.

Cases were diagnosed as active with varying amounts of clinical proof. Those with positive sputum and those hospitalized for tuberculosis may be said to have the most clearcut evidence of active tuberculosis, and thus as a group may be said to be the more serious cases. In these terms, again the areas which have had communitywide surveys had higher rates than did the other areas: The cases hospitalized for tuberculosis plus the positive sputum cases at home amounted to 120 per 100,000 population in the group of survey areas, as compared with only 79 per 100,000 in the other areas (table 1).

Approximately 46 percent of the known active cases in the areas studied were hospitalized. In the area most acutely in need of more beds, only 20 percent of the known active cases

were hospitalized, while in the areas with sufficient numbers of beds, about 80 percent were hospitalized. One large area which was endeavoring to hospitalize all those needing such care had 74 percent of its known active cases hospitalized and still had a short waiting list. These and other data indicate that of the known active cases in a community, approximately three-fourths need and will accept hospitalization, and one-fourth will not be hospitalized at a specific time. This latter group of known active cases will include the few who are unwilling to be hospitalized or who have adequate care at home, those awaiting hospitalization, and those who have been hospitalized previously but whose disease has not yet been arrested. Since cases usually are known to health authorities before they are hospitalized, more complete information on numbers of known active cases may provide a means of indicating hospital bed needs for tuberculosis.

Positive Sputum Cases at Home

From the public health point of view, the cases usually considered most important are the positive sputum cases at home. These are the cases which have been definitely proved to be infectious and which, because they are at home, are in a position to spread tuberculosis to family and community. Information was available from 49 areas on the number of cases at home with positive sputum or other demonstrations of tubercle bacilli. In these areas, 11,760 such cases were known (table 1)—a rate of 26 per 100,000 population. In the surveyed areas, there were 36 cases per 100,000 population as compared with 24 per 100,000 in the other areas. In other words, in the areas with more intensive X-ray case finding, there were more cases at home known to have positive sputum, as well as more cases hospitalized.

Supervision of Cases

How effectively are known tuberculosis cases supervised? How frequently are they ignored as if they were unknown? The effectiveness of health department efforts to determine the sputum status of their known cases is shown in figure 2. Of 34,836 active and activity undetermined cases at home in 36 areas with appropriate data available, 14,965, or 43 percent,

Figure 2. Sputum examination status of active and activity undetermined cases of tuberculosis at home.

were of undetermined sputum status. Communitywide chest X-ray surveys have been conducted in 14 of these areas, and reports reveal less than one-third of the active and activity undetermined cases at home with unknown sputum status, as compared to almost half in other areas.

Health departments generally have the policy of obtaining periodic reports regarding the supervision of significant cases in the tuberculosis case register. Another index of the effectiveness of supervision is the proportion of unhospitalized cases in the register for which the health department has had no examination report within the past 12 months. Although such information was available from only 28 of the areas included in this study, the data are nevertheless suggestive. A total of 47,110 tuberculosis cases at home were classified by examination status, and it was found that 15,815 of those cases, or 33.6 percent (fig. 3) had had no X-ray or clinical examination report within the preceding 12 months. While some of these patients may have been more recently examined, the health department had no information to show that they were receiving either medical or public health supervision.

Communitywide surveys had been conducted in 13 of these areas. For these 13 areas as a

group, 27 percent of the significant cases at home had not had an examination report within the preceding 12 months, as compared with 42 percent for the other areas. Only one community-wide survey area reported a higher than average percentage of cases without an examination report during the preceding year.

Often a distinction is made between the unknown cases in a community constituting sources of infection, and the known cases presumed to be under control and therefore not sources of infection. However, it is clear that there are still large numbers of known tuberculosis cases which, according to health department records, are not being supervised and are probably receiving little more attention from the health departments than are the unknown cases.

In a few areas, data on examination status of patients at home have been tabulated separately for the active cases on the one hand, and for the arrested and inactive cases on the other. It is rather surprising that the active cases at home in these areas show just as high a proportion of cases not recently examined as do the arrested and inactive cases. Since the supervision of active cases at home is generally believed to be far more important than that of the arrested cases, it would appear especially desirable to intensify efforts to obtain examination reports on known active cases.

Estimated Known Prevalence

As indicated earlier, data presented in the foregoing analysis apply only to those areas for which information was available for the 1949 to 1953 period. While these areas represent almost half of the population of the continental United States, they were selected on the basis of the reports available and therefore are not necessarily a random sample. Yet, to a considerable extent, these areas can be tested for representativeness on the following bases: (a) the racial distribution of the population; (b) the geographic distribution of the areas included; (c) the inclusion of areas both with organized local health units and those without; (d) the inclusion of both State and locally directed programs; (e) the adequacy of the tuberculosis control programs in the various areas included, as measured by various indexes, together with data obtained in the course of field

Figure 3. Recentness of medical examination report on known significant tuberculosis cases at home.

consultation; (f) the tuberculosis death rate; (g) the inclusion of areas which have recently had intensive X-ray case-finding surveys; and (h) the inclusion of populations in mental and penal institutions.

In each except the last three of these respects, the group of areas considered in the present study appears to be fairly representative of the continental United States. It was noted, however, that the areas as a group differ from the remainder of the United States in that they had a slightly higher tuberculosis death rate, a disproportionately large number of areas which have had communitywide X-ray surveys, and underrepresentation of the populations of mental and penal institutions. Careful attention has been given to the weighting of each of these three factors in estimating the prevalence of known tuberculosis cases in the continental United States.

By projecting the data contained in table 1, we can arrive at estimates of known tuberculosis prevalence in the continental United States, as follows:

Total known significant cases	450, 000 to 500, 000
Known active cases	225, 000 to 250, 000
Known positive sputum cases at home	35, 000 to 40, 000

These national estimates are probably the best informed guesses as to the size of the tuberculosis problem known to health departments throughout the country. As case reporting and supervision further improve, and as reports from health departments become more generally available, this type of data will become increasingly more meaningful as an index of our tuberculosis control problem.

Summary

1. Tuberculosis case register reports for areas comprising nearly half the population of the continental United States are analyzed.

2. In the areas studied, there was an average of 339 known significant tuberculosis cases and 159 known active cases per 100,000 population.

3. In 43 percent of the cases at home classified as active or activity undetermined, sputum status was unknown to the health departments reporting.

4. About one-third of the known significant cases at home had not had an X-ray or clinical examination within the preceding 12-month period, according to the health department records studied.

5. In the areas which have had community-wide chest X-ray surveys, prevalence rates for known significant cases and for known active cases were substantially higher than in other

areas. The communitywide survey areas had examined the sputa of a higher proportion of their patients and had maintained followup information more satisfactorily than had the non-survey areas.

6. It is estimated that there are almost 500,000 known significant tuberculosis cases in the continental United States, and that nearly 250,000 of them are active. Approximately 40,000 of these are known positive sputum cases at home, and there is an additional large number at home whose sputum status is undetermined.

7. In spite of the rapid decline in tuberculosis mortality, it is apparent that the disease remains a problem of very serious dimensions.

8. In view of the large proportion of cases for which both sputum status information and recent examination reports are lacking, it is apparent that the public health supervision of individual tuberculosis patients is inadequate in many areas.

Twenty-six Years of Cancer Control In Massachusetts

By HERBERT L. LOMBARD, M.D., M.P.H.

MORE THAN a quarter century of experience in cancer control is on the records of the Massachusetts Department of Public Health. With no precedent to follow, with no knowledge of the public health aspects of the disease, without even a clearcut idea that cancer was a public health problem, the State health department launched a cancer control program May 29, 1926.

At the 52d annual meeting of the American Public Health Association, Dr. Eugene R. Kelley, Massachusetts commissioner of public health, pointed out the need for: (a) determination by health department administrators of their proper niche in cancer control; (b) better statistical data on cancer facts and additional personnel and funds to enable health administrators to collect, collate, analyze, and diffuse these facts; (c) extended facilities for early diagnosis and stimulation of the professions to use these facilities fully; (d) better hospital facilities for the inoperable group of cancer patients; (e) new and efficient methods of arousing and retaining public interest in and understanding of the significance of cancer "whereby a large degree of success may be reasonably anticipated even with our present faulty weapons for combating the menace of malignancy."

Today about two-thirds of the States have

Dr. Lombard is director of the division of cancer and other chronic diseases, Massachusetts Department of Public Health, Boston.

Recognition of cancer as a public health problem has led to the development of control programs in all of the States, and in the Territories and insular possessions of the United States. Some of these programs are relatively long established and have evolved not only valuable epidemiological data, but important techniques for coping with cancer as a disease of public health importance.

Effective cancer control programs are distinguished by certain policies and practices uniform to all, and by provisions for meeting the special requirements of the particular area concerned. Such a program is that of the Massachusetts Department of Public Health, described in the accompanying article. *Public Health Reports* from time to time hopes to present reviews of other cancer control programs. That of the New York State Health Department was described in our December 1952 issue.

—THE EDITORS.

some State-supported service or facility specifically for cancer patients (1). But the requirements of cancer programs discussed by the commissioner of public health of Massachusetts in 1923 are still not met.

The component parts of a cancer program are varied, and there is a tendency toward selection of program activity by different units of the population. Physicians often limit the scope of activity to the care and treatment of cancer; sociologists interest themselves in problems connected with the inadequacy of services for those in the lower economic levels of society; individuals interested in research consider this

the all-important field; women's organizations interest themselves in education; statisticians tend to worry over death rates, age distributions, and the like, often forgetting other factors in the cancer problem; and public health workers think of the application of public health methods to cancer control.

The Massachusetts program, consisting of research, hospitalization, diagnostic clinics, tumor diagnosis service, and education, is based on the accumulation of experience gained largely through trial and error. Since Massachusetts was compelled to pioneer, all procedures have been subjected to evaluation in order to gauge their effectiveness.

Statistical Research

The statistical approach is fundamental in a public health program. From statistical studies, the Massachusetts cancer program received its inspiration, determined its scope, evaluated its activities, changed its policies, and obtained new ideas for cancer control.

Our data for research and evaluation, as well as for statistical enumeration, are obtained from the death records, hospital records, clinic records, questionnaires to physicians, records of contacts with individuals concerned in the educational program, followup records, and personal interviews in house-to-house surveys. This material is transferred to punchcards, tabulated, and analyzed.

The findings of several studies conducted by this division, which were either original contributions or a confirmation of the work of other statisticians, demonstrate the scope and type of statistical activities in the program.

It was found that the logarithm of the adjusted cancer death rate increased with the logarithm of the density of the population up to densities of about 4,000 persons per square mile and from there on remained practically constant (2).

Later, the reason for this relationship to density was found to be the high cancer death rate of the foreign-born and their children, both of whom have more cancer than native-born with native grandparents. This was particularly marked for cancer of the stomach.

It has been shown that persons with skin can-

cers are predisposed to other cancers of the skin. Males with lip cancers are somewhat predisposed to multiple skin cancers. There is no evidence that skin cancer provides immunity to other primary cancers (3).

There was a definite association between cancer of the buccal cavity and the use of tobacco (4).

Incidence of cancer among the husbands and wives of cancer patients was found to be no greater than for men and women in the general population.

Cancer of the cervix is correlated with marriage before the age of 20, divorce or separation at any time, unrepaired lacerations, last child born to women before age 25, and syphilis (5, 6).

Cancer of the breast shows correlation with trauma, but the relationship may be more apparent than real.

Hospitalization

The Pondville Hospital, with 139 beds, and the Monsignor Roche wing of the Westfield State Sanatorium, with 50 beds, furnish hospital facilities for patients with cancer or suspected cancer of all types and stages who cannot otherwise be adequately cared for, have lived in Massachusetts for 2 out of the preceding 3 years, and are certified for admission by a practicing physician or dentist. Both institutions maintain outpatient clinics.

In Massachusetts less than 5 percent of cancer cases are cared for in the 2 State cancer hospitals. The present thinking envisions more and more service on the local level, not only for patients with operable cancers, but also for those needing palliative care.

While present trends indicate that few State cancer hospitals will be established, and that adequate service for the patient can be maintained through local institutions, one outgrowth of the cancer hospital program in Massachusetts is pertinent. During the 25 years in which Pondville Hospital has operated, 163 physicians have received specialized training in the treatment of malignant neoplasms. All had had residencies in other institutions. At the conclusion of their stay they were not only proficient in the diagnosis and treatment of cancer

Evolution of the Cancer Clinic Record

but most of them were interested in the entire control program. Nearly half of them have opened offices in Massachusetts communities and the remainder in 28 other States and 2 foreign countries. This increase in the number of trained cancer personnel augurs well for better cancer service.

Tumor Diagnosis Service

A free tumor diagnosis service is offered by the Massachusetts Department of Public Health in conjunction with the Cancer Commission of Harvard University. The service is purchased from the commission at \$3 per specimen. Any physician or hospital may have suspected tissue examined pathologically. This service is used not only by those surgeons who do not have access to other facilities, but also by pathologists who desire confirmation of their diagnoses.

In the early 1930's approximately 2,500 specimens were examined yearly, and slightly over 500 physicians used the service. By 1940 these numbers had increased to 4,000 and 800, respectively. During the war years use of the service decreased, then increased rapidly, until in 1952 nearly 10,000 specimens were examined and 1,125 physicians used the service (see fig. 1).

Clinics

At the present time, 20 hospitals are maintaining State or State-aided cancer clinics. The 18 State-aided clinics are administered by committees composed of physicians appointed annually either by the local medical society or by the staff of a hospital. The staff serves without compensation and the State purchases certain services for the care of "such persons who may be in whole or in part unable to support or care for themselves" (7). The clinics furnish group diagnosis for any individual in Massachusetts whose physician suspects cancer. Individuals may come directly to the clinics, but it is more satisfactory to have them referred by the family physician, who has a knowledge of the patient's previous condition. Any resident of the State may receive an opinion from a cancer clinic regardless of his financial standing. A standard fee of \$10 is paid by the few who are not medically indigent. Medical social service

Figure 1. Number of surgical specimens examined at the tumor diagnosis laboratory and the number of physicians submitting the specimens, 1926-52.

consultation is available and followup service is maintained for all cancer cases from the first admission until death. Only 2.3 percent of the individuals with cancer have been lost to followup service. Among women with cancer of the genital organs and of the breast, the percentage of lost cases is even less—1.5 and 1.6, respectively.

During the 26 years of operation over a hundred thousand new patients have attended the cancer clinics. About one-third have cancer, the predominating sites of which have been skin, breast, female genitals, and mouth. Only 14 percent of the new cancer cases in the State are examined in the State and the State-aided cancer clinics.

In the first year of the clinics 20 percent of the persons who attended were referred by physicians; by 1950 this percentage had increased to 86 percent. In 1950, nearly 20 percent of

Percentage of persons admitted to cancer clinics who were referred by their family physicians, by years

1939.....	79.8		

the persons having cancer came to a clinic within 2 months of the first recognizable symptoms. More than 80 percent of recommendations made at the clinics are now being carried out within 1 month of the clinic admission.

In the cancer clinics the median age of new patients with cancer of all sites except the urinary organs increased from 61.5 in 1930 to 66.0 in 1950. The percentage increase in the median age among women was over twice that among the men.

The clinic attendance greatly exceeds the number of new cases, since each year there are nearly 25,000 return visits of former cancer patients. Studies have shown that the presence of a clinic in a city increases the number of individuals seeking advice for cancer in the physician's private office.

The cost per patient "serviced" by the State-aided clinics at the present time is \$4.30. (Patients "serviced" include those examined at the clinic, cancer patients who returned for check-ups, and former cancer patients visited in the home by a social worker.)

Education

Cancer education of the physicians is accomplished largely through cancer clinics. The State health department issues an abstract bulletin four times a year which is sent to all physicians who request it. In 1940, and again in 1950 the department purchased and presented to every registered Massachusetts phy-

sician a 300-page book, "Cancer, a Manual for Practitioners," published by a local committee of the American Cancer Society.

In 1932, one of the most far-reaching events in medical education in the whole cancer clinic program occurred—the establishment of the first of the cured-cancer clinics. Patients who had been treated for cancer and had been free of disease for 5 years or longer agreed to be present at a clinic at which their case histories were reviewed. The diagnosis of each individual included as a "5-year cure" was verified by a reexamination of the original slide by three pathologists. Practically every site of cancer was represented and more than 150 5-year cured cases were shown.

The percentage of surviving clinic patients who had cancer during the first 25 years of the program is shown in figure 2.

This cured-cancer clinic was followed by teaching clinics, which have enabled the general practitioner to see many more cases of cancer than he would have seen otherwise. Men experienced in cancer diagnosis and treatment, from Boston, New York, and other cities, have conducted these clinics, and the general medical practitioner has been invited to attend the clinic nearest his home. Many physicians who have found it difficult to spend 1 or 2 days in Boston can easily arrange to spend 2 or 3 hours at the local clinic. Between 1933 and the present time, 490 teaching clinics have been held with an attendance of 12,661 physicians.

A cancer institute for nurses is held twice yearly. This institute consists of a concentrated 2-week period of instruction and observation at Pondville Hospital, the State-aided cancer clinics, and various institutions. The course includes discussion of the various sites of cancer from the surgical, pathological, radiological, and nursing points of view, and seminars on the public health aspects of cancer control. The number of nurses attending the institute is limited in order that each nurse may be given individual attention.

Other methods of cancer education have included instruction of medical students, lectures to professional groups, such as nurses, doctors, and public health workers, the distribution of literature and posters, radio broadcasts, and instruction in the schools. The Massachusetts

Figure 2. Survival of clinic patients with cancer during 25 years of Massachusetts program.

Department of Public Health also has published several pamphlets of interest to both the medical profession and the laity.

Between 1935 and 1948 the health department carried on a program of cancer education for the laity through the organization of a cooperative cancer control committee in every city and town in the State. These committees were composed of representatives from all organizations in each community and were formed for the purpose of stimulating each organization to devote one meeting a year to a talk on cancer by a local physician. In 1948, the American Cancer Society assumed the greater part of cancer education of the laity.

Since 1948, the State health department has limited its efforts in lay education to the continuation of evaluative studies of educational methods. A public knowledge survey conducted in Waltham, Mass., in 1949 (8) revealed that nearly three-quarters of the population believed that cancer could be cured. Over four-fifths of the population believed that the disease was not contagious; 81.6 percent knew that surgery, X-ray or radium were accepted treatments for the disease; and 87.5 percent would be willing for the public to know that cancer existed in their families. A little more than half were convinced that the children of cancer patients were in no more danger of developing cancer than the children of noncan-

cer patients. Nearly one-half of the persons in the survey knew none of the seven danger signals of cancer; about one-third knew one of them; and about one-fourth knew two or more. Young adults are better informed concerning cancer than those who are older; individuals in well-to-do circumstances are better informed than the poor, and women have a slightly better knowledge of the disease than men.

Lectures were reported to furnish the most valuable source of information regarding cancer, followed, in the order given, by pamphlets, books, posters, magazine articles, moving pictures, newspapers, personal contact, and the radio.

Problems

In reviewing the accomplishments and the failures during the past 26 years, certain problems relating to knowledge of the disease, attitude of the public, and administration of the program have arisen. At the inception of the program, administrative problems in clinic organization predominated.

The establishment of diagnostic clinics at strategic points throughout the State posed innumerable problems. Some medical societies were reluctant to take the initial step although each had its band of enthusiasts. Many physicians wanted to reserve judgment until the effectiveness of the plan was demonstrated. Others were skeptical and suspicious of this entrance of public health into the realm of cancer. Still others were unaware of the imminence of the program so engrossed were they in their own practices.

The law originally read that these clinics should be established "with or without the consent of the medical profession." This dangerous authority was never invoked, but has been mentioned in the literature on several occasions, the most recent being by Anderson (9, 10, 11). The general practitioner's fear of governmental control of medicine had to be overcome by constantly reiterating that the purpose of the program was to augment the facilities of the individual practitioner, not to supplant them.

In some communities the same group formed the personnel of the clinic throughout the year; in other communities rotating service was used.

Some clinics were maintained in a single hospital; others were divided among several hospitals. In one community a Boston specialist was hired to conduct the clinic each month. In another, each 1 of 7 hospitals wanted a share in the clinic, which met in a rotating service in each hospital. Patients who attended the clinic at one hospital and were advised to return for observation pending diagnosis would wait until the clinic again met at that hospital.

A policy of attempting to convince the medical profession of the value of the program rather than of forcing its acceptance has been followed. In the beginning, group diagnosis was difficult. For example, the dean of medicine in a community was frequently regarded as preeminent, either because of his diagnostic acumen or because of the deference accorded him by younger and less prominent practitioners. Also, after election of new officers in a medical society, sometimes the entire clinic staff was replaced by men who previously had shown no interest in the clinic. These problems have all been overcome gradually.

Many factors regarding malignant disease are a deterrent to program planning, particularly of educational programs. These could be better planned if answers were available to questions such as the following:

In addition to those already known, what occupations or other activities subject the individual to carcinogenic agents?

Is there a constitutional factor in cancer etiology?

Is the constitution of the individual a factor that will influence his response to therapy?

What are the reasons for the relationship between economic status and cancer?

Is the milk factor of importance in human cancer?

Why does early marriage predispose to cancer of the cervix?

What habits of the individual predispose him to cancer?

How much of a factor is heredity in the etiology of human cancer?

What differences in morbidity exist in various geographic areas?

Fear and superstition, as well as ignorance and poverty, have hindered the satisfactory con-

summation of the program. The cancer administrator is constantly beset with lack of qualified personnel; lack of sufficient funds; lack of accurate tests for the early detection of all cancers; lack of sufficient accurate data concerning such factors as incidence of cancer and results of treatment; and lack of general understanding that control requires the combined energies of clinicians, radiologists, pathologists, research workers, and public health personnel. Even though he realizes the temporal limitations of this twofold objective, the administrator visualizes the time when individuals will seek medical attention at the first danger signal, and when the medical profession will be equally alert to furnish the necessary therapy.

Evaluation

The importance of evaluating a cancer control program cannot be overemphasized. Appraisals enable persons in charge of the program to evaluate their efforts. Those portions of the program which do not achieve results commensurate with the time and money expended should be replaced by other types of endeavor. Methods for appraisal cannot be stereotyped and must be altered according to the type of program.

In appraising its program, the Massachusetts Department of Public Health has used as measurements increasing attendance at cancer clinics and hospitals, willingness of the public to listen to cancer lectures, increasing number of magazine articles on cancer, number of individuals willing to work for cancer control, number of other States which have used the Massachusetts program as a pattern, and, probably the most important, the changing death rate. In the early part of the century the age-adjusted cancer death rates for both sexes were rising about 2 percent per year in both the Registration Area of 1900 and in Massachusetts. Shortly before this country entered World War I the increase in cancer death rates among females lessened, somewhat more in Massachusetts than in the Registration Area. Beginning in 1926, the annual percentage increase in the cancer death rate for males was only about one-half that recorded previously, for both Massachusetts and the Registration Area. In the middle

Effect of Public Law 779 On Teaching and Research At Public Health Schools

By W. H. AUFRANC, M.D., and
WILLIAM P. SHEPARD, M.D.

For the majority of persons serving in understaffed health departments and directly concerned with meeting day-to-day public health needs in their communities, the recently published paper (1) on health department manpower shortages was probably far from startling when it revealed that budgeted vacancies amounted to 20 percent for physicians, 9 percent for nurses, and 14 percent for sanitary engineers. But by presenting clearly and concretely the staffing deficiencies in State and local public health departments, a real need has been fulfilled by this study which was sponsored by the Health Resources Advisory Committee of the Office of Defense Mobilization and conducted by the Public Health Service. Now that the nature and scope of the problem have been specifically delineated, the deficits of trained personnel in health departments will receive the attention and interest of many more agencies and individuals at local, State, and national levels.

The reported deficits of physicians and nurses offer an incentive for medical and nursing schools to place more emphasis on public health in their curriculums and in their counseling programs. The same holds true for other categories of personnel.

Partly as a result of the findings in the study

Dr. Aufranc, formerly assistant chief of the Division of Venereal Disease, Public Health Service, is now director of the Health Resources Staff and Dr. Shepard is a member of the Health Resources Advisory Committee, Office of Defense Mobilization. This paper is adapted from remarks given by Dr. Shepard at the 80th annual meeting of the American Public Health Association in Cleveland, 1952.

Public Law 779

Public Law 779, a 1950 amendment to the 1948 Selective Service Act, required registration of all men under 50 years of age in medical, dental, and allied specialist categories, if they were not members of a reserve component of the Armed Forces.

Priority I. Men who pursued their professional education either through occupational deferment or through participation in the specialized training programs of the Army or Navy and had less than 90 days of subsequent military service.

Priority II. Same groups as I, under the same conditions, who had 90 days or more but less than 21 months of subsequent active duty.

Priority III. Men in the specified categories with no active duty since September 16, 1940.

Priority IV. Veterans not covered by priorities I and II.

of manpower in health departments, the Health Resources Advisory Committee surveyed for a second time the faculties of schools of public health to appraise the impacts of Public Law 779 on their teaching and research programs. The information available for 1950-51 and 1952-53 is now being used by the State and local advisory committees to the Selective Service System in determining the essentiality and availability of individual physicians. The data will also serve as a benchmark in staffing and will be useful for mobilization and other planning to meet public health needs.

Findings

For an enrollment of approximately 800 graduate students, the 10 approved schools of public health in the United States reported a faculty of 467 teachers and research workers at the start of the 1952-53 school year. This complement represented a slight reduction from the 488 reported for 1950-51; however, at least a part of the decrease is due to a difference between the 2 years in the definition of faculty members to be included. Some schools, for example, excluded from their 1952-53 reports occasional lecturers who had been included in their 1950-51 reports (table 1).

Table 1. Faculty members at schools of public health, by profession, 1950-51 and 1952-53

Profession	Year of report	
	1950-51	1952-53
Total.....	488	467
Physicians.....	187	179
Dentists.....	2	-----
Veterinarians.....	2	1
Others.....	297	287

To get a more accurate measure of teaching programs in schools of public health than total numbers of faculty members, the Health Resources Advisory Committee in their 1952-53 survey asked the total number of teaching hours for those faculty members with teaching assignments. The reports showed about 84 percent of the faculty members held teaching assignments with some of them devoting as many as 1,000 hours per year. The remaining 15 percent of the faculty members were engaged exclusively in research (table 2).

Since almost all the faculty members with teaching assignments devote a considerable portion of their time to research and community services, the typical teaching schedule of formal classroom time was relatively low. About 46 percent of the faculty members with teaching

Table 2. Total annual classroom teaching hours of faculty members at schools of public health, 1952-53

Annual hours	Total	Physicians	Nurses	Others
Total.....	467	179	22	266
No teaching.....	71	17	1	53
Under 100.....	105	52	2	51
100-199.....	70	30	5	35
200-299.....	42	17	2	23
300-399.....	44	19	5	20
400-499.....	30	17	1	12
500-599.....	10	6	-----	4
600-699.....	17	4	1	12
700-799.....	8	5	-----	3
800-899.....	5	2	-----	3

1,000 and over.....	41	6	1	34
Unknown.....	19	4	4	11

assignments reported less than 200 annual hours of formal classroom instruction. When all 10 schools are grouped, the total hours of formal classroom instruction on an overall basis amounted to 145,000 hours or about 150 to 200 hours per student a year. The individual schools, however, showed marked variations from this overall average, probably because they differed so much from one another by type of enrollment.

An analysis of the classroom teaching hours by academic title and age revealed that most instruction is provided by faculty members with the academic title of associate or assistant professor and that, in general, younger faculty members carry the heaviest teaching schedules.

The percentage of total classroom teaching time contributed in 1952-53 by faculty members according to academic title is given below:

	Percent time
Professors.....	23.6
Associate and assistant professors.....	42.3
Associates and assistants.....	11.1
Instructors.....	8.7
Visiting lecturers.....	9.0
Others.....	5.3

Following are the average annual hours of classroom teaching time contributed by faculty members in each age group:

Age group	Average annual hours
20-29.....	426
30-39.....	379
40-49.....	366
50 plus.....	304

Roughly one-third of the total teaching time in schools of public health during 1952-53 was provided by faculty members in professions covered by Public Law 779. Accordingly, it is especially important for the schools to consider carefully the military liability of these individuals in making faculty appointments. In general, the surveys of the Health Resources Advisory Committee show that they have done this. As a result, they are in a much better position today than they were in 1950-51 (see chart).

As expected, the proportion of men in the first two priorities under Public Law 779 is markedly lower at present than in 1950-51. In

Military liability of faculty members covered by Public Law 779 at schools of public health, 1950-51 and 1952-53

NOTE: Included in the "not liable" group are men over 50 years of age, women, and aliens.

the near future, all men in the first two priorities will have been called for military service, and men with no previous military service, those in priority III, will become liable. On an overall basis, although the picture may be quite different from the viewpoint of the individual schools, the faculty members in priority III contributed 9 percent of the total teaching hours. Men in priority III will be called according to age with the youngest first. It is doubtful if those in the extreme upper-age groups will ever be called at present mobiliza-

tion levels since more and more of the newly graduated physicians are nonveterans and, therefore, will be registered in priority III. The age distribution of the priority III physicians on faculties at schools of public health follows:

Age group	Percent physicians
Under 35	12.5
35-39	20.0
40-44	30.0
45 plus	37.5

Conclusion

The surveys of the Health Resources Advisory Committee show that schools of public health depend on individuals in professions covered by Public Law 779 for more than one-third of their total faculty members. It is, therefore, extremely important for them to follow closely the scheduling of military liability under the law. A comparison of 1950-51 data with 1952-53 information shows that, in general, they have done this. Priority III, the next group in line for military service, at schools of public health contribute roughly 9 percent of the total teaching time. Schools with priority III faculty members in the younger age groups should prepare to obtain replacements now to avoid disruption at a later date.

Immune Serum Globulin

in the prophylaxis of

paralytic poliomyelitis

measles

infectious hepatitis

hypogammaglobulinemia

The summer of 1953 promises to place a tremendous burden on public health administration and private medical practice in the United States in a basic field—that of control of a communicable disease: poliomyelitis. These months could well represent a historical moment in the many-faceted scientific attack on this intriguing and complex virus disease. And this year may well, also, witness the safeguarding of many children from the paralytic effects of poliomyelitis.

On the following pages are presented several basic source and background documents bearing on the distribution and use of immune serum globulin (gamma globulin) in connection with the prophylaxis of paralytic poliomyelitis and other diseases.

The Distribution and Use of Gamma Globulin

a statement issued April 20, 1953, by the Division of Medical Sciences
of the National Research Council

During the past few months, wide publicity has been given to the results of studies indicating that a fraction of human plasma, known as gamma globulin, has some value as a prophylactic agent for paralytic poliomyelitis. As a result of this publicity, an overwhelming demand for the material may be anticipated in the coming months. The purpose of the present document is to outline the steps that have been taken to meet this situation and to discuss briefly the principles on which current plans for the distribution of gamma globulin have been based.

The supply of gamma globulin is severely limited. It is estimated that the maximum amount available this summer will not exceed 10,000 liters. Even if this were all used for the prophylaxis of poliomyelitis in children, it would provide less than one and a half million average doses. Moreover, the dose would be large enough only to give protection for 4 to 5 weeks. How inadequate is this supply to meet the demand will be evident when it is recalled that there are some 40 million children in the United States of America under 15 years of age.

The situation is even less favorable than these figures indicate. Gamma globulin contributes to the public health in ways other than in the prophylaxis of poliomyelitis. It is well established as a valuable agent in the control of measles and of infectious hepatitis. It is proving its effectiveness in the treatment of the rare condition of hypogammaglobulinemia. Provision must be made to reserve amounts of gamma globulin adequate to meet these needs. Furthermore, since gamma globulin is a product derived from human blood, consideration must be given to the requirements of military

and civilian services for whole blood, plasma and albumin. To maintain a well-balanced National Blood Program, blood collected by the American National Red Cross must be wisely apportioned between these varied needs.

Shortly after the outbreak of the Korean War, it was recognized that the competing demands of several Government agencies for blood and the derivatives of blood might become acute. To assure an equitable distribution, the Office of Defense Mobilization was assigned the task of coordinating the National Blood Program. Late in 1952, the evidence for the value of gamma globulin in the prophylaxis of poliomyelitis was first published. Realizing that this new development would lead to an extreme demand for gamma globulin during the next poliomyelitis season, the Office of Defense Mobilization turned to the National Research Council for advice. In response, the Council appointed a panel of experts in public health services, epidemiology and poliomyelitis to study the problem. There was general agreement that the equitable and effective use of available supplies of gamma globulin could be achieved only by the adoption of a system of controlled distribution. In consultation with the foremost authorities on poliomyelitis, an allocation program was devised and submitted to the Office of Defense Mobilization. The recommendations of the panel were approved in principle by the Health Resources Advisory Committee, Office of Defense Mobilization, on April 15, 1953. The plan, in the form which has been communicated to all health authorities, appears on pages 666-668 of this issue of *Public Health Reports*. The discussion that follows is a brief review of the nature of gamma globulin,

the amounts that are expected to be available this summer and the criteria on which the effective use of the material should be based.

Gamma Globulin

Gamma globulin is the name given to one of several fractions of the protein component of human plasma. It is comparable with the product officially known as immune serum globulin. Gamma globulin is prepared commercially by a method involving a series of precipitations with varying concentrations of alcohol under controlled conditions of acidity and low temperature. An average donation of blood (500 cc.) yields 7 cc. of a 16-percent solution of gamma globulin. This represents a single recommended dose for the prophylaxis of poliomyelitis in a 50-pound (6-7-year-old) child.

The production capacity of existing fractionating plants is limited.

The Administration of Gamma Globulin

Gamma globulin is available as a 16-percent solution. This solution is opalescent and somewhat viscous, necessitating injection through a No. 18 or 20 needle for quantities required for the prophylaxis of poliomyelitis. Injections should be made intramuscularly, using a separate syringe and needle for each subject. Gamma globulin should never be given by the intravenous route.

The use of separate syringes is recommended because of the danger of contamination of the syringe with blood containing the virus of homologous serum hepatitis. This may occur when one attempts to withdraw blood in order to be certain that the needle point is not in a vein. It is for this reason that the repeated use of the same syringe carries the hazard of the transmission of homologous serum jaundice. No instance of hepatitis has been recorded following the use of gamma globulin which has been prepared and administered in the manner described above.

The intramuscular injection of gamma globulin is not accompanied by any significant reactions. The danger of local or systemic reactions must, however, be considered if repeated injections are contemplated.

Measles

A dose of 0.1 cc. per pound body weight, when given soon after exposure, will prevent infection in most cases. When given later in the incubation period, this dose will result in modification of the disease. A dose of 0.02 cc. per pound body weight will usually modify the severity of the attack if given soon after exposure to infection.

In general, modification is to be preferred to prevention. Because of the seriousness of the disease in the younger age group, it is suggested that modification be attempted in all children below the age of 3 years who have been exposed to infection.

Prevention rather than modification may be warranted in hospital situations involving debilitated children and in individual cases where there is concurrent serious disease such as clinically active childhood tuberculosis.

The selection of exposed children rarely presents difficulties since the contact is almost always a frank clinical case and the time of exposure can frequently be determined. A history of a previous attack of measles should suffice to distinguish immune from susceptible children, and thus determine the need for prophylaxis following exposure.

Infectious Hepatitis

Evidence for the effectiveness of gamma globulin in the prophylaxis of epidemic infectious hepatitis is of recent origin. The dose recommended at the present time is 0.02 cc. per pound body weight. There is evidence that lower doses will modify the disease. Further studies are in progress to determine the optimum dose range.

The indications for use are less sharply delineated than they are with measles. Inapparent infections may occur and may contribute to the spread of the disease and to the difficulty in identifying susceptible individuals. Moreover, the infection may be spread by means other than direct contact. In food-borne and water-borne outbreaks, control measures directed at the vehicle of transmission should be imposed and may be supplemented by the prophylactic use of gamma globulin.

Gamma globulin should be most useful in the control of sharp outbreaks in the armed forces and in civilian groups where adequate hygienic measures cannot readily be imposed. In the general population, prophylaxis with gamma globulin among the family and intimate contacts of cases would appear to be desirable. At the same time, hygienic controls and the typhoid-type of isolation of nonicteric as well as jaundiced cases should be instituted.

Hypogammaglobulinemia

This clinical entity has only recently been described (1). It is a rare anomaly characterized by a deficient ability to form antibodies. The essential clinical manifestation is the frequent recurrence of severe infections. Laboratory evidence of the condition may be obtained from electrophoretic analyses of the gamma globulin content of the plasma of the patient and from immunological assays. In this condition, the regular repeated administration of gamma globulin is required to maintain the resistance of the patient to infection. As yet there has been little experience with this treatment and dosages have not been adequately established. The physician must be prepared to adjust the dose to the individual response.

Poliomyelitis

Two reports (2, 3) by Dr. W. McD. Hammon and his associates are available on the epidemiological studies which form the basis for the use of gamma globulin in the prophylaxis of paralytic poliomyelitis. The children investigated ranged in age from 1 to 11 years and the doses used were 4, 7, or 11 cc. depending on the weight of the child. The average dose approximated 0.14 cc. per pound body weight.

Significant protection was demonstrated from the second through the fifth week following injection and diminishing protection was evident from the sixth to the eighth week. There was no significant difference in the number of cases of poliomyelitis in the treated and control groups in the week following injection, but there was evidence of mitigation of paralysis in the cases occurring in the children who had received gamma globulin. This evidence is the

basis for the conclusion that gamma globulin will be most effective if given shortly before or as soon as possible after infection. It is of no value after clinical symptoms of the disease have become apparent (4).

Criteria for Diagnosis

It will be noted that the basis for allocation to the States is dependent upon the reported incidence of the disease, with the suggestion that the incidence of paralytic cases may be used as a control in making additional and supplemental allocations.

To insure uniform reporting it is suggested that physicians and health departments adopt criteria for diagnosis similar to those formulated by the National Conference on Recommended Practices for the Control of Poliomyelitis (5). The following is an excerpt from the above document.

"Diagnostic criteria of paralytic or nonparalytic poliomyelitis should generally include three or more of the following:

- 1) history compatible with poliomyelitis,
- 2) fever,
- 3) stiff neck and/or stiff back,
- 4) 10 to 500 cells per cc. of spinal fluid taken during the acute or early convalescent period of the disease,
- 5) spinal fluid protein elevated above normal limits,
- 6) demonstrable muscle weakness or paralysis.

"Cases which present only (1) history compatible with poliomyelitis, and (2) fever, should be classified as presumptive (abortive) poliomyelitis.

"Paralytic cases are defined as those in which definite weakness or paralysis has been detected and persisted during at least two examinations made at intervals of at least several hours. Results of an examination for paralysis of muscles of the extremities or trunk may be very unreliable during the period of muscle tenderness or 'spasm'."

Community Prophylaxis

Community prophylaxis of age groups at the greatest risk is indicated only in areas in which the incidence is exceptionally high and the onset

of the epidemic is abrupt. In Hammon's studies in Harris County, Texas, where the epidemic rate was 82/100,000, only 0.4 cases were prevented per 1,000 injections. The effectiveness rose to 3.4 per 1,000 in the Iowa study where the epidemic rate was nearly 400/100,000. A further difference between these two epidemics lay in the fact that the former was prolonged over many months whereas the majority of the cases in Iowa occurred in a period of 2 months. The effectiveness of mass prophylaxis is proportional to the incidence of the disease in the selected age group during the few weeks following injection and is influenced by the intensity of the outbreak as distinct from its ultimate rate. Mass prophylaxis is most effective if instituted about 3 weeks prior to the peak of an unusually intense epidemic.

Unfortunately, the prediction of the course and duration of poliomyelitis outbreaks in the population size exposed to the greatest risk is difficult and is subject to large error. It is suggested that an area qualifies for initial consideration for community prophylaxis only if it achieves a rate of 40 per 100,000 within a period of not more than 1 or 2 months and has a sharply rising weekly incidence, calculated by dates of onset at the time the selection is made. Other factors useful in selecting epidemic areas are high paralytic rates with relatively increased percentages of respirator cases and deaths. Urban populations exceeding 100,000 will seldom achieve rates justifying mass prophylaxis and populations of less than 15,000 are unlikely to have enough cases, after recognition of epidemic incidence, to make this type of prophylaxis profitable. Areas most likely to qualify are those with predominantly urban populations of 15,000-100,000. In addition to these, camps, schools, and other captive populations are favorable situations for community prophylaxis.

It should be remembered that only 60-70 percent of the expected cases will be influenced, because the rates among older persons are unlikely to be high enough to justify inclusion of all ages in the treated group. It must also be remembered that, if the recommended dose is used, only a 5- to 8-week segment of the epidemic will be affected. In a few instances, it may be necessary to consider a second injection in the course of an outbreak.

Consideration must also be given to the administrative problems involved in the setting up and staffing of clinics and in the administration of gamma globulin to large numbers of children in a short period of time. The viscosity of the solution and the need for large numbers of 10 cc. and 20 cc. syringes present problems.

It is anticipated that the selection of areas and age groups for community prophylaxis will be made by the State health officer or the State allocation authority. If a request for a special allocation be made to the National Allocation Office, the State health officer will be expected to supply information on the case incidence by week of onset, the number of deaths and of respirator cases, and the ratio of paralytic to total reported cases in the area.

Household Contacts of Clinically Diagnosed Cases

During epidemics, the incidence of secondary cases in families is five to twenty times the rate of poliomyelitis in the general population. That is to say, the members of a family in which a case occurs are subject to a much higher risk than are individuals in the community at large. On the basis of risk alone there would appear to be good reason to give priority to the prophylaxis of family contacts. There are, however, no controlled studies of the effectiveness of gamma globulin in the protection of household contacts of diagnosed cases. There is much evidence to indicate that infection is often widespread in families at the time the first case is recognized. If gamma globulin were effective only when given prior to infection, the case for household prophylaxis would be prejudiced. Hammon's results suggest, however, that inoculation after infection but prior to the onset of symptoms may be expected to modify the disease although it may not prevent it. This view bears significantly on the interpretation of the data in the table in which the incidence and chronological distribution of secondary cases of poliomyelitis in families are summarized.

It will be observed that 60 percent of secondary cases occur within 5 days of the diagnosis of the first case. Even if gamma globulin is

administered promptly to the household contacts, it will not be expected to prevent or modify the severity of disease in these cases. An additional 30 percent of the secondary cases will occur within a few days of inoculation. Hammon's results suggest that this group of cases may be mitigated in severity.

Table 1. Chronological distribution of poliomyelitis cases in families following index case

[A summary of data from several sources (6)]

Days interval between onset of first and subsequent cases	Number of secondary cases	Percent	Possible prophylaxis
0-5-----	242	60. 0	None. Modification. Prophylaxis.
6-12-----	120	29. 6	
13-30-----	42	10. 4	
Total-----	404	100. 0	

The final 10 percent of secondary cases will occur in the period in which the protective effect of gamma globulin is maximal and it is this fraction of cases that one may hope to prevent by the use of household prophylaxis. This would, at first sight, appear to be a poor return on the investment were it not a fact that the rates for this small fraction of delayed cases are comparable with the rates among all children in epidemic areas. On this basis, household prophylaxis may be expected to be as effective (cases prevented per 1,000 doses of gamma globulin) as community prophylaxis in the prevention of epidemic poliomyelitis and may be more effective if weight is given to modification as well as prevention of the disease. In areas in which epidemic proportions have not been attained, there will be no justification for general community prophylaxis.

There are a number of administrative advantages associated with household prophylaxis. The population that is to receive gamma globulin is easily defined. Distribution can be carried out through established public health channels and can be made in advance of the poliomyelitis season because allocations do not depend on the precarious prediction of epidemic incidence. Moreover, the cooperation of private physicians is assured since on them will rest

the responsibility for the diagnosis of cases, and the identification and inoculation of contacts.

There is one subjective disadvantage which should not be overlooked. Some 60 percent of secondary family cases will be neither prevented nor modified by the use of gamma globulin. Unless physicians and the public are fully informed of this situation, an unjustifiably critical attitude toward the value of gamma globulin may develop. The public will see the failures of prophylaxis; the successes will be hidden from it.

Intimate Contacts of Clinically Diagnosed Cases

This is simply an extension of household prophylaxis to include individuals who are judged to have been as intimately associated with the diagnosed case as were the members of the household. The extension is logical but raises the difficulty of defining the criteria of intimacy. The method is likely to be most useful in rural and in self-contained suburban communities in which the number of intimate contacts of an individual is limited.

The extension of prophylaxis from household contacts to equally intimate contacts must be used with restraint; otherwise, the allocations to States will be rapidly depleted. It is anticipated that the responsibility for the definition of extra-household contacts and the areas within the State in which this method of prophylaxis may be used to advantage will rest with the State health officer.

Household Contacts of Suspected Cases

The immunization of household contacts of suspected cases may be viewed as a selective form of community prophylaxis which is specifically directed toward those individuals in the community subject to the most intimate exposure to the virus of poliomyelitis at the time that prophylaxis is undertaken. The use of this method is advocated only in intense epidemic situations. It may be particularly valuable in sparsely populated areas in which sporadic cases lead to extremely high rates of incidence but which are not suited to mass prophylaxis.

The method has the merit of giving protection to individuals who may be exposed to infection several days earlier than would be possible were the injections delayed until the phy-

sician could make a more certain diagnosis. There is a further hypothetical advantage which is of quite undetermined value although it may be most significant. Infection with the poliomyelitis virus is much more likely to be abortive than paralytic. It follows that the first invasion of a family by the virus is probably evidenced only by a case of minor illness. Should the case actually be one of poliomyelitis, immunization of the family at this time may prevent any paralytic case from developing.

The prophylaxis of contacts of suspected cases has serious disadvantages. Its efficacy is just as dependent as is that of community prophylaxis on the accurate prediction of epidemic conditions. If it is used in other than epidemic areas, much gamma globulin will be squandered on contacts of minor illnesses, a negligible proportion of which are poliomyelitis infections.

The method has been described as a selective form of community prophylaxis. It differs in that the office of every physician in the area will become a prophylactic clinic. From one point of view, this will simplify administration by avoiding the problems that are associated with the organization of centralized clinics. On the other hand, if a significant fraction of the total population in the area is involved, it may overtax the physicians and result in undesirable delay in completing the required number of injections.

Summary

It is estimated that about 1,000,000 average doses of gamma globulin will be available for the prophylaxis of poliomyelitis during 1953. The selection of the group of individuals in which this limited supply of material can be used most effectively presents many epidemiological and administrative problems. Four alternative methods have been recommended by the division of medical sciences, National Research Council, and have been incorporated in the allocation plan adopted by the Office of Defense Mobilization. The advantages and disadvantages of these methods in particular situations are reviewed. The allocation plan is based on the principle that it is the local health officer who is in the best position to decide which method of prophylaxis will most effectively meet each local situation as it arises.

The household contact plan would appear to be the most effective in areas of low or moderate incidence, with possible extension to include intimate contacts other than family members. With high epidemic incidence in a community with an intense outbreak, either community prophylaxis of age groups particularly susceptible or extension of the household contact plan to include contacts of suspected cases may be suitable. Factors such as community size, expected severity and duration of the epidemic, facilities for the injection of large numbers of individuals and the availability of gamma globulin may influence the decision as to the plan for emphasis in a particular area.

The plans are of sufficient latitude, however, to apply to almost any situation, and appear to offer some hope of restricting the use of the scarce material to the groups at greatest risk.

During a severe epidemic there is a possibility that suspect cases, rather than confirmed cases, would serve as guides to some of the children most likely to have been very recently exposed or currently undergoing exposure. Injection of these children may have a selected advantage since some of these suspect cases will represent true primary infections in families and the whole train of possible subsequent paralytic cases occurring after the span of one incubation period would be prevented. Based on cases prevented to thousands of injections given this method may have some advantage. On this basis, this method can in no way be considered less effective per dose given than injection of all children at one specific time.

Distribution Within the State or Territory

While it is recognized that the exact method of distribution will vary within the States and Territories, it is recommended that:

Private physician should request gamma globulin from the local health department or other health authority.

It is further recommended that in order to

obtain gamma globulin for prophylaxis, physicians should be required to furnish the name and date of onset of the case, as well as the names, ages, and weights of household contacts to be inoculated.

It is also recommended that the basic allocation of 60 cc. per case reported (p. 666, col. 2, l. 12-30) be interpreted to indicate the average amount needed for prophylaxis of household contacts of clinically diagnosed cases. The actual amount distributed to the physician for this purpose will vary depending on the number and ages of the household contacts involved.

Public Education

It is recommended that:

In a coordinated program of public education, the Office of Defense Mobilization make widely known such details of the allocation plan as it may see fit to adopt and implement.

If desired by the Office of Defense Mobilization, the Panel on Allocation of Gamma Globulin shall undertake further consideration of a plan for public education both lay and professional.

Progress in Research on Poliomyelitis

By HARRY M. WEAVER

RESEARCH is primarily and essentially a journey into the unknown, for the principal purpose of solving problems that disturb us, and for which we have no satisfactory solution. Prerequisite to the solving of any problem is the exploration, study, and understanding of all those areas of knowledge that are related directly or indirectly to the problem which has been posed. Without the benefit of the perspective that comes with such knowledge, one encounters the grave risk of deciding, prematurely, that a problem has been solved, only to learn to his sorrow, at some future date, that all of the relevant facts were not at hand.

Although great forward strides have been made in the general field of the medical sciences, far more remains to be learned than is known today. I am inclined, therefore, to be somewhat hesitant in drawing sweeping conclusions relating to poliomyelitis, because, it seems to me, the many voids in our knowledge of the medical

The "journey into the unknown" of poliomyelitis is traced from before 1938 to the present—and projected into the future—by one who has been along much of the journey.

sciences leave us without the depth of perspective we should have.

Limitations and Scope

It is impossible for any one individual totally to comprehend the program of research against poliomyelitis. Seldom has there been assembled such an array of talent, representing so many diverse fields of scientific specialization, all working toward a single common objective. The intensity with which the individual members of this coordinated team carry out their work results in an ever growing and ever changing body of knowledge about poliomyelitis. No sooner does one investigator tentatively suggest a concept to explain some unresolved problem, than we find one or more other workers subjecting that concept to the acid test of quantitative experimentation. This constantly changing body of knowledge causes no little confusion in the minds of those persons who attempt to keep abreast of this progress. But, because this program of research is dynamic, our knowledge about poliomyelitis is approaching with unusual directness and rapidity the objective for which we all strive, i. e., the absolute and total truth.

Because of the fact that we are conducting research on so many different aspects of poliomyelitis—the virus, its host, the acute disease, its after-effects, methods of prevention and of treatment—it is difficult for any one individual to stay abreast of even the basic principles, and it is impossible for him to comprehend totally

Dr. Weaver is director of research for the National Foundation for Infantile Paralysis. Before taking this post in 1946 he was on the faculty of the College of Medicine, Wayne University.

This informal review of research, here somewhat condensed, was presented at a special meeting of the Board of Trustees of the Foundation in New York City on January 26, 1953. In his talk, Dr. Weaver pointed to limitations of time and space, remarking his "regret that it has been necessary to omit many very interesting and several potentially important observations."

the inferences and subtleties of this rapidly changing body of knowledge.

Finally, because poliomyelitis so frequently results in crippling, because this disease selectively affects most commonly the healthy child in the very bloom of his youth, because poliomyelitis is prone to strike with such dramatic suddenness, we are understandably anxious to rid ourselves of the dread that this affliction will strike down one of those dear to our own hearts. It is only natural, therefore, that into any report on research we try to read a new cure, a new preventive, or, at least, a new means of ameliorating the crippling after-effects of this affliction.

A Review of Progress

My intention is not to state or imply that the means are now at hand whereby we can protect ourselves from the paralytic consequences of an infection with the virus of poliomyelitis, but rather to review, within the limitations to which I have already referred, the very considerable progress that has been and is being made in an effort to provide some practical means to control this disease. We may examine the results of research in the field of poliomyelitis in relation to four different periods of time: (a) prior to 1938, (b) from 1938 through 1947, (c) from 1948 through 1952, and (d) the years that lie ahead.

As we discuss the research of prior years, we should not lose sight of the fact that in all fields of human activities—and the medical sciences are no exception—hindsight, as compared with foresight, is very much more penetrating, illuminating, and satisfying. In assessing the work of prior years, we have available a vast body of scientific knowledge that simply did not exist when that research was being conducted. And may I be the first to point out that the body of scientific knowledge, to which I have just referred, is not by any stretch of the imagination of the making of the National Foundation for Infantile Paralysis and its grantees alone. We have unhesitatingly applied to our work in poliomyelitis, where applicable, knowledge that has emerged through no effort of ours, but because some individual or group supported an investigation on some

problem which seemed totally unrelated to poliomyelitis. We are fortunate that a sharing of knowledge is the accepted way of research. Indeed, it is not unlikely that when the work of the National Foundation has been completed, history may record the fact that its greatest contribution was not the bringing forth of some practical means to control poliomyelitis, but that it stimulated and supported a cooperative effort of many scientists, from which effort emerged the knowledge requisite to fashioning the answer to one of man's even more distressing problems.

The Years Before 1938

The National Foundation for Infantile Paralysis was created in 1938 for the purpose of initiating and supporting a comprehensive effort by scientists to develop some practical means whereby man could protect himself from the paralytic consequences of an infection with the virus of poliomyelitis. That was, and continues to be, the principal objective of this organization.

It is very difficult to describe accurately our knowledge of poliomyelitis as it existed in 1938. Research on any subject progresses in an orderly fashion through several sequential stages, of which the principal ones are: (a) the construction, on purely theoretical grounds, of a concept to explain one or more aspects of the problem; (b) the modification of the concept in accordance with what are believed to be all of the facts relating to the problem; and (c) the evaluation of the concept by controlled and critical experimentation.

Facts and Misconceptions

The scientific literature, prior to 1938, contains many statements about poliomyelitis that have subsequently been proven to be true. This literature also contains a vast array of misconceptions. It is not too unfair to say that, for the most part, knowledge about poliomyelitis in 1938 was so limited in extent, and so lacking in experimental proof, that it was difficult for the investigator of that day to distinguish between fiction, wishful thinking, and fact.

In 1938, the science of virology was in its swaddling clothes. Only a handful of workers

were qualified by training and experience to conduct critical investigations in this field. The tools required to carry out scientific research on poliomyelitis were, for the most part, crude prototypes of those available today; and even they were in such short supply, and so expensive, that it was a fortunate worker indeed who had an opportunity to work with them. Furthermore, most work on poliomyelitis required use of monkeys, with the result that research was even further limited to those very few individuals who could obtain financial support in large amounts. In an attempt to continue work without adequate means of support, it appeared necessary to carry out with one or two monkeys experiments that should never have been attempted without utilizing scores of these animals. The result was a long period of confusion with respect to the immunology and other aspects of poliomyelitis.

Foundation Stones

However, the work on this disease prior to 1938 was by no means all bad, as may have unintentionally been implied. It is a matter of record that there were laid the foundation stones of the program of research that exists today. The significant contributions of that period include: (a) a reasonably comprehensive description of the clinical disease; (b) proof that this disease is caused by a virus; (c) finding of an animal host, the monkey, suitable for experimental studies with the virus; (d) the demonstration that the crippling after-effects of poliomyelitis occur only as an aftermath of damage or destruction of nerve cells by the virus; and (e) suggestive evidence that the virus may be transmitted from person to person without the assistance of an extrahuman vector.

The more serious of the misconceptions that we inherited, and with which we subsequently had to deal, included the belief that (a) the disease is caused by only one type of virus; (b) the virus is capable of reproducing itself only within nerve cells; and (c) the virus enters the body through the nose, and subsequently travels through the body exclusively within nerve fibers. These particular misconceptions are referred to because they tended to fix the direction of research.

The Period 1938-47

The results of research from 1938 through 1947 are difficult to describe. One of the more important accomplishments of the period was the training of additional workers and the organization of properly equipped laboratories so that a truly comprehensive and effective program of research against poliomyelitis could be instituted.

In that era we began to find out exactly what happened in the body following an infection with the virus of poliomyelitis. We learned that when disease did occur following exposure to the virus, the manifestations of disease might extend from a slight and transient fever on the one hand, to paralysis and death on the other. We learned, also, that an individual could become infected without exhibiting the slightest evidence of disease. We learned, in fact, that a "silent infection" with the virus is the rule, and that paralysis is the rare exception.

We discovered also that the digestive tract of man constitutes both the portal of entry and the portal of exit of the virus. Moreover, human beings constitute the principal reservoir of the virus in nature. We learned also that the order of frequency with which individuals may be found to be excreting the virus may be listed as: (a) the individual with acute poliomyelitis, (b) household associates of the case, and (c) close, personal, extrahousehold associates of the family. We determined also, as one would logically expect, that the virus could be recovered in nature from those species of flies that feed and breed on human excreta. Admittedly, we were disappointed to learn that fly abatement programs did not modify epidemics of this disease.

During that same period of time, we learned that in relatively unsanitary parts of the world where it is rather easy to isolate regularly the virus in close proximity to human beings, paralytic poliomyelitis occurs much less frequently, usually in children under 5 years, and almost never in epidemic form. Comparing such regions with other parts of the world where modern sanitation is the rule, and where one seldom isolates the virus in nature except during the time of an epidemic, we find that the paralytic disease is more common, the disease is more

likely to afflict older persons, and epidemics are the rule rather than the exception. Thus, we have the paradox of more paralytic disease in those parts of the world where there is less virus, and a lesser incidence where virus is more regularly found.

A closer scrutiny of this seeming paradox revealed the interesting fact that individuals living in those unsanitary—but nevertheless relatively poliomyelitis-free—parts of the world almost invariably had poliomyelitis antibodies in their blood. Furthermore, they acquired these antibodies at a far earlier age than in other parts of the world. The finding that a mixture of antibody and virus was incapable of causing disease suggested that antibodies might play a useful role in the body's defense against paralytic poliomyelitis. However, an attempt to utilize this observation to fashion a useful agent against paralytic poliomyelitis had to await the next era of research.

Advances in Treatment

The period 1938 through 1947 was also one in which great strides were made in developing more effective treatments for individuals afflicted with the disease. While it is true that no existing form of treatment has been shown to be capable of limiting the spread of the paralytic process, methods have been devised which, if correctly employed and instituted early enough, are most effective in preventing contractures of muscles. In prior years, it was the progressive contracture of muscles that brought about the horribly misshapen bodies so frequently encountered as a result of poliomyelitis.

This same era witnessed the rapid development of methods of treatment which, although incapable of curing paralysis, enabled the afflicted individual to utilize to the fullest extent possible the motor nerve cells which had escaped destruction by the virus. During that same period we began to develop more effective methods of treatment for those unfortunate individuals suffering from respiratory paralysis.

Influences on Severity

It was during this era that we learned for the first time that certain factors influence the severity of the paralytic consequences of poliomyelitis. For example, it was discovered that

paralysis is more extensive and severe in those afflicted individuals who continued exhaustive physical activity during the febrile state of the disease, and that an individual is especially prone to develop the bulbar form of the disease if he contracts poliomyelitis within 30 days after removal of his tonsils and adenoids. Unquestionably a few individuals escaped the more serious consequences of poliomyelitis by taking cognizance of these observations; but the number of individuals spared must have been pitifully small. It was also observed that the incidence of paralysis is increased during pregnancy.

Paradoxical as it may seem, we also learned much when it seemed that we were learning little. We tried to circumvent many of the difficulties inherent in poliomyelitis research by attempting to unlock the secrets of poliomyelitis through work with other viruses for which simple laboratory methods were available. Although we learned a great deal about subjects other than poliomyelitis, it soon developed that the indirect approach left much to be desired. As we view that period in retrospect, it becomes painfully evident that we compounded, all too frequently, the most glaring error of the previous era—that of conducting research with inadequate numbers of animals. Again it had to be learned that conclusions drawn from improperly conceived and inadequately controlled experiments, far from contributing to progress, are apt to so confuse the issue that a practical solution to the primary problem may become buried under a mound of misinformation.

Lessons of a Decade

Thus ended another era, comprising 10 years of work. More investigators had been trained, laboratories had been organized and equipped, many experiments had been performed—experiments which had yielded a very considerable body of knowledge; but, we had failed to enunciate, on even the most tentative basis, any method for control of paralytic poliomyelitis that was worthy of critical trial.

As that period drew to a close, it became evident that, if real progress were to be made, more exact methods of research would have to be instituted, objectives would have to be clearly defined, procedures and techniques would have

to be developed to permit attaining these objectives, and individual groups of workers would have to concentrate their energies on one, or at most a very few, of the objectives.

The 1948-52 Era

During the period 1948 through 1952, the National Foundation for Infantile Paralysis instituted a policy of holding frequent informal conferences with small groups of its grantees. These "off the record" conferences provided an opportunity to critically evaluate, on a continuing basis, the status of the various research problems relating to poliomyelitis. It was in these meetings that the deficiencies in our program of research became obvious. It was here that objectives were defined, experiments designed, and workers found who were eager to devote their undivided attention, if need be, to carry out the experiments required to attain the objectives set by the group.

Reliance on group thinking to guide research can be, from an administrative point of view, a disappointing experience. However, if those concerned are principally motivated to achieve success in the total program; if the individual contributors are allowed the right to range without penalty along lines that may be ahead or even contrary to the thinking of the group; and if the conferences can be conducted in a spirit totally divorced from any employer-employee relationship—under these conditions, the effectiveness of group thinking is a stimulating experience to behold.

Credit for much of the progress in this period should be given to the many individuals who, without personal recognition, so generously contributed their thinking and suggestions to other investigators. The ingenuity, the quality, and the decisiveness of many of the recent reports on poliomyelitis reflect the effectiveness of this coordinated thinking and planning.

One of the first recommendations to come out of these conferences was that exact methods of research must be the rule. This meant fewer experiments per year, though at a vastly increased cost per experiment.

So that adequate numbers of monkeys would be available for such experimentation, and to assure delivery of uniform animals to each of

the various laboratories so that the work of one could be compared with that of any other, the National Foundation established a monkey conditioning center. This center provided housing for 3,000 animals, and the supply and distribution system allowed for delivery to grantees of more than 20,000 fully conditioned monkeys annually. Without this operation many of the studies that have brought us to the point we have reached today could not have been carried out.

Determination of Virus Types

At the beginning of this era of research, we had good reason to suspect that human poliomyelitis might be caused by more than one type of this virus. Of all the problems we have undertaken to solve, none has been of greater fundamental importance than the establishment of this fact. Any hope of controlling poliomyelitis with preventive or curative drugs, preventive serums, or with vaccines; any hope of learning how the disease is transmitted from individual to individual through population groups; any hope of developing a satisfactory explanation for the fact that this disease does not affect all persons to the same extent and degree—a solution for these, and for other important problems as well—demanded that we first determine exactly how many different viruses are capable of causing human poliomyelitis. And, should more than one type of the virus be found to exist, we knew that we would then have to determine the distribution of each in nature, the capabilities of each to induce disease in the human being, and the capacities of each to induce immunity to whatever number of other types might be found.

The solution of this problem necessitated the monotonous repetition of exactly the same technical procedures on virus after virus, 7 days a week, 52 weeks a year, for 3 solid years. The number of monkeys utilized in this effort is legion. The physical effort expended by the investigators to cope with the struggles, the dodges, and the antics of this horde of primates, is almost beyond comprehension.

But, in spite of these and other difficulties, this problem has been solved. At a cost of more than \$1,370,000, we have learned that there are three different types of the virus circulating

throughout all parts of the world, each capable of causing paralytic poliomyelitis in the human being. We learned also that development of immunity to any one of the virus types did not convey similar immunity to either of the two remaining types. It was also observed that within each of these types, individual strains of the virus were encountered which appeared to be less virulent than other members of the same type.

These findings stand as one of the most important milestones in research against poliomyelitis.

The Role of Antibodies

Once we knew how many different viruses one had to protect against, it was possible to return to an observation that had been made prior to the era we are now discussing: The discovery that poliomyelitis antibodies are present at an early age in the blood of individuals who live in those parts of the world where paralytic poliomyelitis is seldom encountered. Such antibodies are found also in the blood of most adults, irrespective of where they might reside. These antibodies appear also in the blood of monkeys following recovery from an attack of poliomyelitis or subsequent to vaccination against the disease. There are, of course, three different poliomyelitis antibodies—one for each of the three different types of the virus.

Since these antibodies are found only in the blood of animals or human beings who seldom if ever become afflicted with the disease, and since such antibodies are capable of inactivating virus, it seemed to be of paramount importance to determine whether these antibodies are an essential link in the mechanism for protection against paralysis, or whether they represent some nonuseful byproduct of the process of infection.

There followed a number of animal experiments from which one could safely draw the conclusion that, if poliomyelitis antibodies are present in the blood in sufficient amount prior to an infection with the virus, the incidence of paralysis is materially reduced, and, under certain circumstances, may be entirely prevented. But this was the result in the laboratory, where it is possible to select the route of inoculation of the virus, and the amount and kind of both

antibody and virus that are injected. Furthermore it is possible in the laboratory to administer these substances separately in accordance with a time schedule most favorable for the result desired. The next and obvious question was: Are these antibodies capable of protecting against the paralytic consequences of a natural infection with the virus in human beings?

Immune Serum Globulin

Fortunately, other workers had already succeeded in their efforts to develop methods to permit extracting, in concentrated form, these antibodies which are present in the blood of most adults. This product was already in commercial production, under the name of "immune serum globulin," ordinarily referred to as gamma globulin, and had already been shown to be effective against two other viral diseases, measles and infectious hepatitis. Through the courtesy of the American National Red Cross, a very considerable quantity of this valuable material was made available.

As soon as this material could be made ready for use in the field, a Foundation grantee undertook to determine the capacity of this substance to prevent paralytic poliomyelitis in human beings. The plan for this investigation exemplifies what can be accomplished through group thinking, and its execution is a fitting tribute to those who worked so hard and skillfully toward so important an objective.

Results of Field Trials

This experiment yielded two important results: (a) An agent which, if it could be made available in sufficient quantity, man could employ to protect himself against the paralytic consequences of a natural infection with the virus; and (b) a vastly more important result—the knowledge that this protection could be attributed to poliomyelitis antibodies circulating in the blood in relatively small amounts.

The field trials demonstrated quite conclusively that an injection of a sufficient quantity of this substance will confer some protection against the paralytic disease. However, the duration of effectiveness, in the dosages employed, was limited to about 6 weeks; and during the first week of this period, paralysis would appear to be lessened in severity, rather than

prevented, although the number of cases developing paralytic poliomyelitis within 1 week of an injection of gamma globulin was too small to determine for certain whether or not paralysis was ameliorated.

To further complicate this situation, immune serum globulin is obtained from the blood of human beings, and has heretofore been manufactured in rather small amounts. Because of limited manufacturing facilities and supplies of human blood, we cannot hope for the production of more than a very small fraction of the amount of this material that will be sought by the American public. A central allocation authority has been established to provide for the distribution of all of this material. This will provide a mechanism to insure, insofar as it is possible to do so, the most efficient use of this scarce product.

We are fully cognizant of the fact that immune serum globulin is not a practical answer for poliomyelitis. We knew, before the field trials were ever conducted, that when poliomyelitis antibodies are injected into the body, they disappear within a relatively short period of time. If, on the other hand, the body is induced to manufacture its own antibodies, as it does following an infection with the virus, such antibodies remain in the blood for long periods of time, perhaps for many years. The principal reasons for doing the field trials were: (a) to determine whether or not naturally occurring paralytic poliomyelitis is preventable by poliomyelitis antibodies; and (b) if so, what are the minimal amounts of these antibodies that must be circulating in the blood at the time of an infection with the virus. The results of the field trials support the concept that paralytic poliomyelitis could be prevented by vaccination, if the vaccine could induce the body to produce each of the three different poliomyelitis antibodies in sufficient amounts.

Significance of Tissue Culture

But, in spite of the progress so far described, I would be very skeptical of our achieving any practical method for control of poliomyelitis within the foreseeable future were it not for yet another important discovery. This was the development of methods whereby all three types of the virus of poliomyelitis may be grown on

small bits of human or animal tissues which are themselves growing in test tubes.

We have only just begun to realize the real significance of this remarkable discovery—a discovery equally applicable to a host of problems quite remote from poliomyelitis. In previous years, an investigator had no other alternative than to use large numbers of monkeys when he sought to determine whether a given material did or did not contain virus, and, if it did, in what amount and of what kind. Similarly, monkeys had to be employed to determine the amount and kind of antibody that might be present in a given sample of blood. Today, all of these experiments can be done in test tubes, and the results can be ascertained in less than one-fourth as many days as when monkeys were required.

In prior years, we could not undertake, with any reasonable hope of success, studies designed to determine the chemical and physical configuration of the virus particle. We were unable to do this because the virus could neither be obtained in sufficient quantity, nor in a simple enough menstruum, when the only source of virus was from the central nervous system tissues of monkeys. Today there is no practical limit to the amount of virus that can be produced.

Prior to the discovery of methods for growing virus in test tubes, we were without any cheap and effective laboratory procedure to sort out, from among the hundreds of thousands of chemical compounds that exist, those relatively few that might be worthy of critical trial against poliomyelitis in animals. Today, such tests are being performed in test tubes. In years past, we had far less chance than today of developing an effective vaccine. Why? Because we did not have a method that was sufficiently uniform for producing large quantities of virus; and also because viruses obtained from the nerve tissues of monkeys are contaminated with small amounts of other substances which, when injected into the body under certain conditions, are liable to precipitate destruction of the recipients' own brain tissues. It is relatively easy to standardize the growth of viruses in test tubes; and when such viruses are grown on other than nerve tissues, they are apparently free of these harmful substances.

These are not all of the practical applications that have stemmed from the development of methods for growing viruses in test tubes. But this may be enough to show why this discovery alone has, in my opinion, earned the right to be designated the keystone of modern research on poliomyelitis.

We have come to the end of the present era with a sufficient body of knowledge to know with certainty that there can be fashioned, in at least one of two ways, a practical method for control of human paralytic poliomyelitis. The first of these two methods is through use of drugs; the second is by vaccination.

Drug Potentialities

There are several reasons why the first of these objectives might be a less desirable method of control. For example, drugs are usually not effective for long periods of time and, except in the face of an epidemic, it would be difficult to insure widespread use of preventive drugs on a continuing basis. Further, if there is developed a method for control of poliomyelitis with drugs capable of arresting the spread of the disease process, one would then have to recognize that in most cases the virus would have already wrought some damage before it could be brought under the influence of the drug.

Until this past year, our attempts to find an effective drug were somewhat discouraging, because we had not developed adequate experimental methods to select chemical compounds worthy of clinical trial. Now, however, the technical difficulties have in part, at least, been overcome, with the result that we are in a much more favorable position to detect reasonably effective compounds, if such compounds exist, or if they can be made.

Vaccination Outlook

However, it would appear that the most likely way to develop an effective and practical method for control of human paralytic poliomyelitis would be through vaccination. With this method of control we would not have to await an outbreak of the disease, as we would if electing to control poliomyelitis through preventive or curative drugs. On the contrary, vaccination could be carried out prior to the expected appearance of the disease, with a much greater

chance, therefore, of providing protection for all.

There are many different methods by which an effective vaccine might be prepared. The scientific literature shows that with serial passage of the virus through an unnatural host, the virus tends gradually to lose its capacity to invade nerve tissues and destroy nerve cells, without losing its capacity to stimulate production of protective antibodies. It now appears that one of the best procedures for producing this effect is that of growing the virus in test tube cultures of living tissues. From the theoretical point of view, vaccines prepared in this way should be the most effective of all. However, it is impossible to predict from animal experiments whether or not such preparations would be safe to use in human beings. Much laboratory work remains to be done before such vaccines can safely be administered to man. In a similar stage of development is another possible method of vaccination, in which living virus of all three types is administered following an injection of immune serum globulin. While these and other possible methods of vaccination are far from being ready for field trial, we may be assured that research will reflect increasing attention to these possibilities.

Finally, studies in both experimental animals and human beings have demonstrated that prior treatment of the virus with certain chemicals may so change the virus particle that it is incapable of damaging nerve cells but still able to induce formation of antibodies. Admittedly, a vaccine prepared in this way would have lost some of the capacity of untreated virus to elicit antibody formation. Fortunately, there is good reason to believe that the disadvantages resulting from chemical treatment of the virus can be largely overcome by administering the vaccine in conjunction with certain potentiating oils.

Maturation of Research

As we examine the research that was conducted from 1948 through 1952, it becomes evident, that during this era, research on poliomyelitis attained sufficient stature to stand on its own two feet. Only a few short years ago, much of our work was done with other viruses in the rather desperate hope that in this way we would learn something about poliomyelitis for

which we did not have techniques to permit of effective study. Following full documentation of the work that has already taken place, it would not be to surprising to find other workers in the years to come using the virus of poliomyelitis in the hope that they may learn something about other pathogenic agents.

Research of the Future

In light of recent progress, some may hope for a positive statement as to whether or not a practical method for control of human paralytic poliomyelitis is "just around the corner." Inasmuch as research is truly an exploration into the unknown in an attempt to solve a problem for which there is no presently available solution—one must reply that if we knew exactly when and by what means we could provide the solution for a particular problem, there would be no need to conduct research. As we understand the problem of poliomyelitis today, it would be unrealistic to think that a practical method for control awaits the discovery and application of some undiscovered fundamental principle or even a new technique. It would seem that we are now in possession of the scientific principles and tools required. But, although hope in the hearts of men will undoubtedly continue to spring eternal, and such hope with respect to poliomyelitis is not without some very considerable basis in fact, no one can safely predict when that longed-for day will come. The only truthful answer is this: A practical method for control of paralytic poliomyelitis will never be forthcoming unless research is continued.

It is in this present era that we have reason

to expect many important forward steps will be taken. In some instances this may mean moving from work on animals to studies with human beings. Such transitions necessarily entail some calculated risk. Often it is quite impossible to determine, in advance of doing such studies, the degree of risk involved. Those who propose such steps should not be surprised if more voices are raised in opposition than in support. The investigator will be hard-pressed to distinguish between risks of reasonable probability on the one hand and risks of unlikely possibility on the other; and he must recognize that among the outcries may be those motivated by fear or due to an incomplete understanding of the problem or to an incomplete appreciation of the social responsibility of science. Perhaps the scientist contemplating such steps can gain some comfort from the provocative observation of Raymond Fosdick that "what is wrong with the world of today is not the dreams of the idealists, but the cynicism of those who call themselves realists."

Summary

It is apparent that there has been tremendous progress in the fight against poliomyelitis, and that we are now in possession of many of the tools and basic facts with which will ultimately be fashioned a practical method for control of this affliction. It is impossible to say when this objective can be achieved, since much hard and exacting work still remains to be done. But with greater knowledge for more intelligent planning and with sharper tools for more precise experimentation, the attainment of our goal seems to be moving ever closer.

The WHO Tuberculosis Research Office

—A Review of the First Four Years—

By I-CHIN YUAN, M.D., Sc.D., and CARROLL E. PALMER, M.D., Ph.D.

AFTER the second World War, mass BCG vaccination programs were started in several countries of Europe as an emergency measure to combat tuberculosis. The work of tuberculin testing and vaccinating was conducted under the auspices of the International Tuberculosis Campaign (ITC), an organization established by three Scandinavian voluntary organizations (the Danish Red Cross, Norwegian Relief for Europe, and the Swedish Red Cross), and joined in March 1948 by the United Nations International Children's Emergency Fund (UNICEF). Through such united effort and support, the campaign was extended to millions of persons in many parts of the world. And, as this was the first time that BCG vaccination had been done internationally on such a large scale, it was not surprising that problems and questions arose for which there were no answers. The need for systematic and carefully controlled investigations of BCG vaccine and vaccination became increasingly apparent.

Dr. Yuan, formerly deputy director of the WHO Tuberculosis Research Office, is now WHO liaison officer at the New York headquarters of the United Nations International Children's Emergency Fund (UNICEF).

Dr. Palmer is director of the WHO Tuberculosis Research Office, Copenhagen, and chief of the field research branch, Division of Chronic Disease and Tuberculosis, Bureau of State Services, Public Health Service, Washington, D. C.

At the invitation of UNICEF and ITC in the fall of 1948, a field survey was made and a report (1) was presented to the Joint Health Policy Committee of UNICEF/WHO on the possibilities for scientific research in connection with the mass BCG vaccination programs. The committee recommended the report to the Director-General of the World Health Organization; and the WHO members of the committee brought it to the attention of their Executive Board. As a result, the World Health Organization established the WHO Tuberculosis Research Office (TRO), in February 1949, in Copenhagen.

Method of Investigation

The work of the WHO Tuberculosis Research Office is essentially one of applying scientific methods to technical field problems connected with the international BCG program or arising from its operations. For this, TRO has assisted and cooperated with many national and international organizations including: the Danish National Health Service, the Danish State Serum Institute, and the Danish National Anti-Tuberculosis Association; the Finnish National Anti-Tuberculosis Association; the Tuberculosis Control Service of the Icelandic Government; the Union Mission Tuberculosis Sanatorium at Madanapalle, India; the international BCG Pilot Station at Paris; the Public Health Service of the United States; the International Tuberculosis Campaign; and the WHO Tuberculosis Section which took over the work of the ITC in July 1952.

To obtain reliable results, great care is taken in the design and the execution of each investigation and in the analysis of the results. This requires appropriate statistical concepts and methods; a trained technical staff to assure uniform techniques and accurate and unbiased observations; study groups of sufficient numbers and comparable controls; and, above all, critical judgment in drawing conclusions. Such requirements are, of course, essential for scientific work, but their value cannot be overemphasized in clinical and public health research. Unfortunately, in some countries, the use of controls as a legitimate method of research in studying the treatment and prevention of disease in man is not generally accepted, either by society or by the medical profession. Any attempts of this kind are often opposed as "experimenting" on human beings. Laboratory studies on animals are fundamental to the understanding of disease processes in man. Clinical control studies, however, are essential if progress is to be made in solving many of the problems of man's health and man's diseases.

New Research Laboratory

With the current extension of the WHO/UNICEF BCG program to many countries where BCG has been little used and where reliable information on the nature and prevalence of tuberculous infection and disease is lacking, the need for scientific inquiry becomes even more apparent. TRO's experiences have repeatedly shown that what is found to be true in one area frequently fails to hold as true for another area where people live under different environmental, economic, and social conditions. If serious mistakes are to be avoided in the conduct of large-scale BCG campaigns, preliminary surveys and BCG studies should be made by competent pilot teams to determine suitable techniques and criteria for vaccination and the type of results to be expected.

The Tuberculosis Research Office has hitherto put great emphasis on human field studies, although the need for basic laboratory research has been recognized for some time. A generous offer by the Danish National Health Service from their UNAC (United Nations Appeal for Children) funds together with yearly contribu-

tions from the Tuberculosis Research Office made it possible in 1952 to create an international laboratory, the Tuberculosis Immunization Research Center, where a closely coordinated program is now operating to study the complex problem of tuberculosis immunity through integration of results from both the laboratory and the field. The laboratory was established within the premises of the Danish State Serum Institute in Copenhagen by agreement between the World Health Organization and the Danish Government.

Research Program

When the mass BCG campaign was started, the technique of tuberculin testing and vaccinating was formulated largely on the basis of experience in the Scandinavian countries, although it was recognized that changes might have to be made as the work was extended into different parts of the world. This proved to be so. Tuberculin testing procedures were repeatedly modified, and critical problems were encountered when the vaccination results were found to differ widely from what was expected. The research program developed by the Tuberculosis Research Office, therefore, involved a variety of short-term and long-range investigations which comprised almost the whole subject of BCG vaccine and vaccination from the tuberculin test to the efficacy of mass BCG vaccination in the prevention of tuberculosis. (See the outline of TRO activities, p. 680.) Its object was to place tuberculosis immunization on a rational and scientific foundation.

One of the first responsibilities that TRO agreed to undertake was to direct the collection of BCG campaign statistics and to analyze and prepare the material for publication. At the conclusion of the International Tuberculosis Campaign in June 1952, a total of 38 million children had been tuberculin-tested, and 18 million of the total had been vaccinated with BCG in 23 countries. This was the first time that mass immunization of such magnitude had been conducted on an international scale. The opportunity it offered for collection of information on tuberculin sensitivity was without precedent. The technique for the tuberculin test

Objectives	Operations	Results
TRO STATISTICAL DOCUMENTATION OF MASS BCG CAMPAIGNS		
To assist the International Tuberculosis Campaign in organizing field statistical work and training of local statistical personnel.	Before January 1952—statistics from 23 countries in Europe, North Africa, the Middle East, Asia, and Latin America.	Annual and monthly statistical summaries for International Tuberculosis Campaign.
To compile statistics and prepare reports on tuberculin testing, vaccination, and postvaccination testing of national campaigns.	At present—statistics from Aden Colony, Iran, Pakistan, India, Burma, Thailand, Formosa, Hong Kong, the Philippines, Malaya, Costa Rica, El Salvador, Jamaica, and Trinidad.	Individual reports documenting completed campaigns in 12 countries.
To handle WHO/UNICEF campaign statistics after conclusion of International Tuberculosis Campaign in June 1952.		Reports for Lebanon and for Palestine refugees included in ITC second annual report (3). Simplified procedures introduced for collection of field statistics.

EVALUATION STUDIES OF BCG VACCINATION IN TUBERCULOSIS PREVENTION

Danish Mass Tuberculosis Campaign

To develop national roster of the tuberculin-tested, X-rayed, and vaccinated for long-range followup of tuberculosis morbidity.	Joint program with Danish National Health Service and Danish Anti-Tuberculosis Association for countrywide campaign in Denmark (except Copenhagen.)	Punch card records made for 1.2 million persons of whom half vaccinated during campaign or before.
Special studies of relation of allergy and X-ray findings to incidence of tuberculosis.	Campaign started in early 1950 to cover 1.5 million persons aged 1-6 and 15-34 years and to include tuberculin testing, vaccination, and X-ray examination of adults.	Special studies conducted to evaluate and improve methods of tuberculin testing, X-ray examination, and selection of persons for vaccination.
		Improved compulsory national notification of pulmonary tuberculosis.

Finnish Mass BCG Campaign

To study long-range effect of mass vaccination on tuberculosis mortality through national roster of the tested and vaccinated.	Cooperation with Finnish Anti-Tuberculosis Association and Finnish National Office of Vital Statistics in operating a statistical office in Helsinki and analysis of tuberculosis mortality statistics.	Work on roster begun September 1949; copying of some 1 million cards for population 1-25 years.
		Punch cards completed for 850,000 tested and vaccinated.
		Matching of tuberculosis death certificates against roster now progressing.
		Steps under way to verify tuberculosis deaths for acute forms of the disease.

was relatively uniform. Usually the test was made with a standard tuberculin produced by a single laboratory. In many countries, only a single low-dose test was used. Record forms were also standardized.

Statistical Documentation

Almost all the data sent to Copenhagen have now been published in 14 reports documenting the campaigns by individual country (2, 3).

WHO Tuberculosis Research Office (TRO), Outline of Activities, 1949-53—Continued

Objectives	Operations	Results
BCG VACCINE AND VACCINATION STUDIES		
To investigate basic factors influencing allergenic potency of BCG vaccine with particular reference to problems arising in international BCG campaigns.	Studies chiefly in Denmark; also in Mexico, southern India, and Egypt under joint auspices of International Tuberculosis Campaign, Danish State Serum Institute, and TRO.	Approximately 23,000 school children vaccinated in 27 projects. Retesting after 6-12 weeks completed in all 27 projects.
To study dosage and age of vaccine, exposure to light and heat, qualitative differences between living and dead bacilli, vaccination techniques, and so forth.	Program of testing, vaccination, and periodic retesting of school children supplemented by laboratory work at Danish State Serum Institute on vaccines used.	1-year retesting completed in 20 projects. 2-year retesting completed in 8 projects.
To compare vaccines prepared by different laboratories.	Close cooperation with national and local health services and officials, BCG production laboratories, and BCG Pilot Station in Paris.	Work in Denmark to continue on reduced scale. Work in other countries being extended.

LABORATORY INVESTIGATION

To undertake laboratory research on tuberculosis immunity and immunization with particular reference to BCG.	International Tuberculosis Immunization Research Center established within premises of Danish State Serum Institute (Copenhagen). Supervision and coordination by joint committee of 4 (2 each from WHO and Danish Government).	Temporary director of center appointed. Bacteriologist and biochemist appointed. Work begun October 1952 in newly built laboratory.
--	--	---

These 14 reports describe how the campaign was conducted in each country and what tuberculin test and vaccine were used. They give detailed statistical information about tuberculin sensitivity rates in each district or county within each country. Such information has great epidemiological value for comparing tuberculin sensitivity among countries and among areas within a country. Sensitivity to a low dose of tuberculin is perhaps the best single index of tuberculosis that can be obtained for many countries today where morbidity and mortality statistics are either not available or are unreliable. Some of the reports also contain information on postvaccination retesting. During the early ITC campaigns, some retesting was done in various countries, but no conclusions could be drawn because of the variability of the methods. Since the autumn of 1950, however, specially trained teams have

been sent to Ecuador, Egypt, Greece, India, and Syria to make systematic surveys of postvaccination tuberculin allergy. Analysis of the results revealed significant geographic differences, posing further problems for research.

Because tuberculosis is still the leading cause of death in almost all the Asian, East Mediterranean, and Latin American countries, a cooperative field research station has been set up in Madanapalle, India, with the assistance of the Indian Government, to study the epidemiology of tuberculosis in a rural population. The work is geographically limited in scope, but it is expected that the results will increase our understanding of the nature, prevalence, and spread of tuberculosis in a tropical region and the effect of BCG vaccination on the course and frequency of the disease. Similar epidemiological studies are also in progress in Iceland (4) where the insular position of the

Objectives	Operations	Results
EPIDEMIOLOGICAL STUDIES OF TUBERCULOSIS IN TWO DIFFERENT COMMUNITIES Madanapalle		
To investigate prevalence, nature, and spread of tuberculosis and to investigate certain control methods in this rural Indian community of 52,000 population, including 175 surrounding villages.	Madanapalle Field Station established through cooperation of the Indian Government and the Union Mission Tuberculosis Sanatorium at Madanapalle.	Approximately 42,000 persons tuberculin-tested and X-rayed; 11,000 of these BCG-vaccinated. Retesting and X-ray reexamination of 10,000 persons in 1951-52. 185 patients diagnosed and treated. Basic information transferred to punch cards for annual followup. Analysis under way.
Iceland		
To investigate prevalence, nature, and spread of tuberculosis and to investigate certain control methods in this insular country of 140,000 population.	Project with cooperation of Icelandic Government for countrywide studies. Central office at Reykjavik.	National roster to include information on tuberculin sensitivity and X-ray findings for the population by household groupings. Plans for followup of tuberculosis morbidity and mortality. Detailed records for many years being transferred to punch cards.

country and the efficient health services favor long-range followup. BCG has been used sparingly in Iceland.

Other long-range projects were designed to study the changes of tuberculosis morbidity and mortality in relation to mass BCG vaccination campaigns in Denmark (5) and Finland (6). National rosters of the tested and vaccinated have been set up in Denmark to permit direct matching of current morbidity reports and in Finland for matching of death reports. Tuberculosis morbidity or mortality of the vaccinated may thus be compared with that of the non-vaccinated (natural reactors to tuberculin) and with the expected trends in the general population.

Vaccination Studies

Early in the ITC campaign, in the summer of 1948, unusually low tuberculin conversion

rates were reported from one country (Poland). It was thought that possibly the potency of the vaccine had been reduced by failure to keep it cold, but several other possibilities were also considered, and it soon became clear that many questions about BCG simply could not be answered at that time. By taking advantage of the national BCG vaccination program of school children in Denmark, arrangements were made for tuberculin testing, vaccination, and followup to be conducted by special TRO research teams so as to provide answers to some of those questions. Emphasis was first placed on the effects of various physical factors, particularly temperature and duration of storage. More questions arose as the studies progressed and were extended to other countries. To date, 27 separate field research projects have been completed in which approximately 44,000 school children have been tuberculin-tested, and more

Objectives	Operations	Results
STUDIES OF THE TUBERCULIN TEST AND TUBERCULINS		
<p>To study specificity of the tuberculin test with particular reference to selection of noninfected persons for vaccination in different parts of the world.</p> <p>To investigate causes of low-grade reactions observed in tropical and subtropical countries.</p> <p>To develop suitable methods for field standardization and comparisons of tuberculins.</p>	<p>Work conducted by special TRO-directed teams cooperating with national and local health authorities in Denmark, Egypt, Finland, Holland, Iceland, India, Mexico, Norway, Pakistan, and the United States of America.</p>	<p>In addition to the 23,000 children tested in the BCG vaccine studies, approximately 93,000 children and adults and 4,100 tuberculous patients tested with standard PPD, many with duplicate tests using varying doses and different antigens.</p> <p>Need for further investigations of significance of different kinds of tuberculin sensitivity clearly indicated.</p>

CONSULTATION AND TRAINING

<p>To advise on technical matters of mass BCG vaccination previously conducted by the International Tuberculosis Campaign and now by WHO/UNICEF.</p> <p>To assist WHO Tuberculosis Section and regional offices in training selected physicians, nurses, and statisticians for BCG work.</p> <p>To acquaint health officers and WHO fellows from various countries with TRO work and methods of investigation.</p>	<p>Training by senior staff members of TRO.</p> <p>Includes statistical evaluation projects, field vaccine studies, and co-operative research program connected with Danish tuberculosis campaign.</p>	<p>Increasing number of international and national officials visit WHO Tuberculosis Research Office for conferences and discussions on technical problems of BCG vaccination.</p> <p>Requests for training of BCG personnel increasing.</p> <p>During 1952, 36 health officers from 23 countries and 15 WHO staff members and fellows have spent from 1 day to 2-3 months in TRO.</p>
--	--	---

than 23,000 nonreactors among the 44,000 children have been vaccinated and retested at regular intervals.

The results of some of these studies have been reported in separate papers (7, 8). All have recently been drawn together and published in the form of a monograph (9). The results have proved different in many respects from what has been generally accepted. For example, it was believed that the vaccine had to be kept cold and used within a short time after preparation, that large numbers of living organisms were needed to obtain a satisfactory allergic response, and that the potency of a vaccine could be adjusted simply by minor changes in the amount of BCG per unit volume.

None of these has been confirmed. Instead, it has been shown that the vaccine can be kept for 10 weeks at 2-4° C. without significant loss of its allergenic potency; and storage at 20° C. for a month or 37° C. for 5 days causes only a slight reduction in the level of tuberculin allergic response. Vaccine could be diluted tenfold or given in twice the usual dose without causing a significant change in allergy.

On the other hand, the depth of injection of vaccine was found to have considerable practical consequence. Although the level of allergy is not affected, the size of the local lesions at the vaccination site as well as the frequency of abscesses increases with deeper injections. Differences in depth of injection may therefore

explain why a greater proportion of complications was found in some of the campaign areas than in others, even though the same vaccine was used in all of them.

Exposure to Light

Although it has been common knowledge that many biological products are harmed by light and undue exposure should be avoided, the practical significance of the effect of light on BCG vaccine was not recognized until the poor results found in Egypt and other southern countries by the retesting teams prompted the search for some powerfully destructive agent. Exposure of the vaccine to sunlight was naturally suspected and a series of experiments was planned and carried out. The results showed that light has a devastating effect on the vaccine. After 30 minutes' exposure to direct sunlight, the postvaccination Mantoux reactions decreased in mean size from 20.5 mm. to 8.6 mm.; the vaccination lesions decreased in mean size from 9.0 mm. to 5.5 mm.; and the colony count of BCG organisms was reduced approximately a thousandfold. A substantial decrease in colony count was seen after exposure of the vaccine to the sun for only 5 minutes. Subsequent laboratory studies in the Danish State Serum Institute at Copenhagen have shown that exposure to ordinary daylight through the double glass laboratory windows during the preparation of vaccine also can cause a large reduction in the number of viable organisms. One of the results of the field and laboratory research is that the laboratory procedures have now been modified to avoid light exposure during the preparation and handling of the vaccine and, at the same time, WHO/UNICEF vaccination teams have been advised to take similar precautions in the field.

Degree of Sensitivity

Differences have been observed among vaccines produced by different laboratories. Some workers claim that these are due to variations between strains of BCG. Field studies, on the other hand, have shown that varying proportions of living and dead organisms may account for a great deal of the observed differences. Vaccine composed entirely of dead (heat- or light-killed) organisms produces a low level of

allergy, but mixtures with living organisms can produce almost any level of allergy, depending on the relative proportion of each component. Moreover, there appears to be some kind of interaction between living and dead BCG: The addition of only a small fraction of living organisms to killed vaccine produces stronger allergy than would be expected from the sum of the two acting independently.

Throughout the research program, tuberculin sensitivity—the kind induced by BCG as well as the naturally occurring kind found in unvaccinated persons—is shown to be quantitative (10–14). It is appropriately described in terms of degree rather than as simply being present or absent, positive or negative. After vaccination, for example, the sizes of the tuberculin reactions of a group are generally found to be fairly closely concentrated. Some reactions are smaller than the average, and some are larger, yet the population as a whole responds to vaccination with much the same degree of tuberculin sensitivity. The degree of sensitivity, in turn, depends on the particular batch or strength of vaccine used. Some vaccines induce tuberculin sensitivity as high as that found from natural infection, and the same high degree of BCG-induced sensitivity is still present after 2 years. With other vaccines the group response is of a low degree. Irrespective of the degree of sensitivity, however, the average size of the postvaccination reactions is shown to be a simple, useful way to describe results for a group of persons given the same vaccine or to compare results with different vaccines. The more familiar method of noting the percentage of positive reactions gives far less information and may even obscure large differences in the degree of sensitivity induced by different vaccines.

Tuberculin tests on some 44,000 school children in Denmark, Egypt, India, and Mexico to select those eligible for vaccination show that there are at least two kinds of naturally acquired sensitivity (15). One kind, strong reactions to a weak dose of tuberculin, is found everywhere. This is designated as high-grade or specific sensitivity, and it undoubtedly results from infection with virulent tubercle bacilli. Its frequency generally corresponds with the prevalence of tuberculosis. The other

kind, called low-grade or nonspecific sensitivity, is distinguished by small reactions to a weak dose of tuberculin and fairly large reactions to a strong dose. Found only in some countries, or in some areas within a country, it has no relation to the prevalence of tuberculosis (16, 17). The existence of nonspecific sensitivity, even though its cause is still unknown, necessarily has a direct bearing on the validity of tuberculosis infection rates based on the combined frequency of weak- and strong-dose tuberculin reactors in some parts of the world. It also raises practical problems in how to select persons for vaccination and how to evaluate the results of mass vaccination programs.

Future Tuberculosis Research

The work of the Tuberculosis Research Office has perhaps brought forth more questions than it has answered. It may be appropriate, therefore, to examine broadly the direction of future research to serve best the needs of international tuberculosis control programs.

Since Koch's discovery of the tubercle bacillus in 1882, repeated attempts have been made to vaccinate against tuberculosis, but the outcome of most efforts has been disappointing. The protective value of BCG in man is still a highly controversial subject. The great difficulty is that, with a few exceptions, a comparable control group of unvaccinated persons has not been used to measure the effect of BCG in the vaccinated. More control studies must be made in places where the prospect of success is good and cooperation is obtainable. In accepting responsibility for mass campaigns, we have an obligation to assess the efficacy of BCG vaccination in the control of tuberculosis.

The problem raised by the existence of a nonspecific kind of tuberculin sensitivity has far-reaching implications for all forms of tuberculosis control work. The cause of this sensitivity must be sought out and identified. At the present time, the evidence points to an infection with some sort of nonpathogenic agent or agents, possibly an acid-fast organism, which is highly prevalent in some geographic areas. Intensive research is now under way to approach the problem from different sides. Meantime, it is important that the pattern of tuber-

culin sensitivity be carefully studied in different parts of the world to determine where nonspecific sensitivity exists so that suitable steps can be taken to avoid overestimating tuberculosis infection rates, to modify criteria used in selecting persons for vaccination, and to evaluate postvaccination allergy more realistically.

Other Areas for Research

For practical BCG work, it is of great importance to know whether or not vaccinated individuals showing a high degree of tuberculin allergy are better protected, as some believe, than those with a low degree of allergy. This is a serious question in view of the fact that retesting surveys have revealed unusually low levels of allergy among the vaccinated populations in a number of countries. The same finding may obtain in other countries where no systematic retesting has been made or where BCG programs are being, or will be, conducted. Should individuals with allergy below a certain level be revaccinated? At the present time we do not know. The relationship between allergy and immunity is still obscure; in fact, we still know very little about immunity in tuberculosis. There are many problems to be worked out by combined laboratory and field research.

Finally, a conspicuous opportunity for medical research has arisen in connection with the intensive efforts being made against tuberculosis by international organizations. There are many countries today where tuberculosis is the leading public health problem and where reliable knowledge about the disease is lacking. It is naive to believe that orthodox measures of tuberculosis control, although they may have been effective in western Europe or in North America, are necessarily applicable in countries where conditions of life are different.

The only rational approach, perhaps also a more economical one in the end, is to combine technical assistance programs in such countries with a simultaneous program of scientific research. Undoubtedly, the same can be said about other phases of international public health work. What is practicable in one country may fail in another unless a sound basis for application has been found or the results of preliminary studies support its use. And as

international organizations are increasingly concerned with technical assistance to underdeveloped countries, the complementary role of scientific research must not be minimized.

NOTE. A selected bibliography of WHO Tuberculosis Research Office publications and other reports related to international tuberculosis research may be obtained from the authors. Copies are also available at the Tuberculosis Research Office, World Health Organization, Scherfigsvej 8, Copenhagen, Denmark.

"New occasions teach new duties"

Using a quotation from James Russell Lowell's *The Present Crisis* as his theme and title, a Harvard professor of public health practice examines pertinent changes in social and health affairs. He assesses the effects of these trends on public health as a specialty of preventive medicine.

By HUGH R. LEAVELL, M.D., Dr.P.H.

TODAY we are all shaken by a rapid succession of changes which threaten to rip us loose from the very roots of our past. These roots are so comfortable and reassuring that we tend to overlook Marcus Aurelius' advice in his *Meditations* to "observe always that everything is the result of a change, and get used to thinking that there is nothing Nature loves so well as to change existing forms." It is not too difficult for us to accept the idea that our business in public health is to get others to change their behavior to make for healthier living. But when we ourselves are called upon to change, the idea is less acceptable.

Two major types of changes with which public health must deal are going on in the modern world: "public" changes and "health" changes. Our professional training helps us most with the health changes. Our knowledge of biology, chemistry, and physics and their medical sub-

specialties helps us find and use the proper immunizing agents to prevent disease, the right kinds of food to eat, the best sprays to kill mosquitoes, and so on. We can usually adjust rather readily to rapid changes demanded as a result of research which provides better tools with which to combat health problems.

The public changes that are so important in public health work are in many respects more difficult for us to appreciate. Most of us have limited backgrounds in the basic social sciences—sociology, anthropology, psychology, economics, and political science—that might help us understand better the people with whom we must work. Yet public changes are often of even greater importance than health changes. For example, resistance to adoption of practices proven desirable by health research may completely nullify the usefulness of the research. This is illustrated by the situation in an Indian jute mill where malaria seriously hampered production. Although the mill operators provided antimalarial drugs without charge, only 15 percent of the employees took advantage of the opportunity to improve their health. Studies are now in progress by social anthropologists and physicians to learn the reasons behind this failure.

More and more we are beginning to recognize the importance of the public changes in our work and are striving to make up for our deficiencies in training in these areas of knowledge. We still have a long way to go. We also have prejudices to overcome, which tend to make us place higher values on the results of

Dr. Leavell, professor of public health practice at the Harvard School of Public Health, is president-elect of the American Public Health Association. He was chairman of the executive board of the Association from 1948 to 1952 and was director of health in Louisville, Ky., for several years.

This paper was presented as one of the keynote speeches at the opening session of the biennial conference of the State directors of public health nursing with the Public Health Service and the Children's Bureau, held March 9-13, 1953, in Washington, D. C.

health research than on those of social research. This appraisal may have been justifiable in the past, but it is likely to be increasingly less so in the future. Social science is finding the scientific method quite as useful as natural science has found it.

Health Changes

We still need to remind ourselves constantly that the increase of man's life span by 18 years in half a century has more profound medical, economic, and social implications than such developments as atomic energy, air transportation, and modern communication. Increased life expectancy at birth is giving this country a population with an increasing proportion of aged persons and is causing us to retool from programs for controlling communicable disease to plans for dealing with degenerative disease and long-term illness.

As health changes have developed, it has become possible for the preventive medicine attack to shift successively from emphasis on the environment, in the sanitation phase, to emphasis on the agents of disease, in the bacteriological phase, to emphasis on the human host, in our present stage of development.

We are also changing some of our concepts about certain diseases, and we are finding that communicable disease control and sanitation may not have entirely unmixed blessings. Ultramodern sanitation, for example, may increase susceptibility to poliomyelitis. Studies in certain African areas have indicated that a high percentage of the local population is immune to poliomyelitis, and that clinical cases of poliomyelitis are extremely rare. Presumably the people there are more or less immunizing themselves by drinking diluted sewage containing polio virus. Prevention of German measles in girls may lead to their later developing the disease as pregnant women and giving birth to children with congenital deformities. As antibiotics control bacterial diseases and more and more new viruses are found, one begins to wonder whether the viruses simply take over when the bacteria are brought under control. As more lives among prematurely born infants are saved and retrolental fibroplasia increases among those saved, one again begins to wonder

a bit. Puerto Rico offers another illustration of how progress may create new problems. Following the introduction of sanitation and communicable disease control measures, the population in this island increased so rapidly as to introduce malnutrition.

These illustrations suggest that unilateral public health must give way to a multilateral approach. We must think seriously and consistently of calling in those who should be our teammates working in agriculture, industry, and education to produce better balance in program and result.

Five Levels of Prevention

Greater knowledge of the natural history of disease opens up new possibilities for a unified attack by all members of the health team. Natural history in this sense is "the process of departure from health, beginning with the very first forces that inaugurate it in the environment or elsewhere, through the resulting changes that take place in man, and until equilibrium is reached or defect, disability, or death ensues" (1). Increasing knowledge of this natural history makes it possible to attack the environment, the agent, or the host at strategic points. Thus, prevention in the broad sense of the word may be achieved at five possible levels: (a) health promotion, (b) specific protection, (c) early recognition and prompt treatment, (d) disability limitation, and (e) rehabilitation, listed in the order in which they become applicable in the stages of the disease process.

Health promotion is directed not at a particular disease or disorder but toward furthering general health and well-being. Attention to nutrition during periods of growth and development and physiologic changes, encouragement of optimal personality development, application of genetic knowledge, health counseling of various types, and health education are examples of activities at this level of prevention. Involving much more than what health workers can do unaided, health promotion includes activities of educators, agricultural specialists, economists, and industrialists.

Specific protection intercepts the causes of disorder before they involve man. Activities at this level, which include immunization

against communicable disease, prevention of dental caries, and control of insect disease vectors, have long been characteristic of health departments and certain voluntary health agencies.

Early recognition and prompt treatment is effective in preventing the spread of disease to others if the disease is a communicable one; in curing or arresting the disease process if specific treatment is available; in preventing complications or sequelae; and in shortening the period of disability. Case finding in the early stages is the foundation at this level.

Disability limitation involves preventing or delaying the consequences of clinically advanced or noncurable disease. As our knowledge of natural history of various disease processes increases, we may anticipate less and less activity at this level of prevention, though there will obviously always be need for it in truly degenerative diseases. This and the preceding level of prevention are those at which work of private practitioners and hospitals has been largely concentrated in the past.

Rehabilitation is concerned with preventing complete disability and economic dependence. It may begin while the disease process continues; it becomes the major method of attack when the disease is stationary. Only recently have we begun to develop activities at this level of prevention, though in some other countries rehabilitation is in a relatively advanced stage of development.

If we keep in mind the natural history of disease and these five levels of prevention, it is apparent that there are opportunities in preventive medicine for all those in the health field, whether they be in health departments or other health agencies, private practice, or hospitals, and for workers in education, agriculture, and industry as well. Each has a part to play; each can contribute to the total attack against disease and toward the promotion of health.

Viewed in this light, public health as organized community action is a part of preventive medicine. The public health agency may be either voluntary or governmental. Private practice also plays a very important part in preventive medicine, and as preventive medicine concentrates more and more upon the host, the

opportunities for private practitioners to practice broad preventive medicine increase. In the future, health departments and other health agencies will likely contribute more and more to private practitioners' work with individual patients and their families. Thus continuity of care by a single practitioner may be more possible than it has been in the past. The attitudes of people are usually favorable to those who help them in illness, and there may well be a carryover value when preventive services are tendered, making these services more acceptable.

Hospitals in the future will have a broadened concept of their place in the community, and their activities will be at all five levels of prevention. Rather than concentrating principally on early diagnosis, prompt treatment, and disability limitation, they may be expected to give increased attention to rehabilitation. As more patients are treated "vertically" rather than "horizontally," health promotion and specific protection also will be employed more widely by hospitals.

Increased knowledge of health problems has necessitated specialization. There is simply too much to know for a single individual to be an expert in all fields. Valuable though it is in many respects, this specialization makes it difficult for the layman to find his way about among the numerous specialized practitioners and health agencies.

Public Changes

The rapid changes in social organization have necessitated such rapid adjustments as to impose severe strains on our adaptive mechanisms. A good deal of evidence indicates that these problems of adaptation have contributed materially to the increased incidence of psychosomatic disorders and mental ill health generally. The troubled political situation of the world today casts its shadow over us all. Industrialization with its mass production favors urbanization. Mechanization, even on the farm, has greatly changed living conditions. The increased leisure time now available to most of the population has created new wants as yet only poorly met. Improved living standards and full employment have lessened the old insecurities of laboring groups.

Large-scale organizations, both governmental and private, tend to create a sense of powerlessness in the individual. The individual, however, needs to participate; his capacity for participation must, therefore, be cultivated to a degree never before necessary.

An unprecedented geographic and social mobility tends to break down the ties of neighborhoods and fixed communities as well as ties with family beyond the immediate husband-wife-child complex. Children are no longer regarded as producers, but as consumers. In the small family each member tends to cherish more fully the others. There is opportunity not only for optimal physical and mental development, but knowledge of the means towards maximum personality realization is becoming more widespread. Parenthood is getting to be a profession; the child is seen more and more as a product of his home and his environment.

Equality between the sexes is being approached and many fields of endeavor are now open to women. One result of this change is that the nursing profession no longer can count upon a vast supply of recruits. Other pursuits, more remunerative and less exacting, have first call.

Social attitudes are changing, and more emphasis is being placed on the dignity and worth of the individual. This has led to diminishing discrimination and the broad acceptance of social security as a right. The period of *laissez-faire* economy has passed, and varying degrees of governmental control have been imposed with varying degrees of acceptance. The leveling of incomes after taxes has greatly reduced individual large-scale philanthropy, with profound effects upon voluntary agencies.

Technical Assistance Programs

With all these changes, positive and negative in effect, economic development has proceeded at virtually a geometric rate in the United States so that this country is pulling further and further ahead of its nearest rivals. To assist in holding the free world together, an international program of technical assistance has been developed to help people in underdeveloped areas help themselves. We are finding that to

do this effectively we cannot impose American ways on these people but must understand the people, their culture, and their problems.

Even in transferring strictly technical health knowledge and practices and in using modern health supplies and equipment, we must understand the basic scientific principles involved so that modification can be made to meet local needs. We must discover what are the frills and what are the essentials. Then the essentials must be made available with a minimum amount of cultural shock to the people who want help. The privy, essentially a hole in the ground, is an example. It is unimportant for its public health purpose whether the privy has a seat or whether the squatting position is used in defecation. Yet many a privy has gone unused simply because the American "sitting" model was imposed on people without taking time to discover their "squatting" habits.

The help we give does not fill a vacuum: It must replace something that is already there. As an illustration, two articles on health appeared recently on a single page of the *New York Times*. One related to a group of scientists, among them several Nobel prize winners, who were setting off to Asia to spread modern health knowledge. The other, taking up twice as much space, described the important place which witch doctors still play in Madagascar. These Nobel prize winners must compete with such witch doctors before they may have their own wares accepted.

In these technical assistance programs it is particularly necessary to develop teamwork between health workers and those who work in agriculture, industry, and education. Public health can be an admirable spearhead for this team since it has acceptable ends to offer, shows tangible results, and can, through training local people, make them relatively self-sufficient.

Public Changes in Health Fields

In considering the effects of social changes in the health fields, we are beginning to see integration and coordination as answers to the problems of specialization and the need for unity of health services. Medical prepayment plans reduce the need for charity, and, if they are comprehensive, promote early diagnosis. Group

practice provides the ultimate skills of medicine in one place. Health centers enable health departments and voluntary health and welfare agencies to join in providing broad services to a neighborhood. Hospital and health department combinations make for economy and efficiency. Extension of hospital services to include home care reduces heavy hospital expenses and supplements the resources of the home. All of these services tied together in regional organizations promote smooth and economical functioning. Many different types of specialists are beginning to work together as teammates, and auxiliary workers are being recruited for less skilled jobs.

Overall health planning is receiving increased interest as manifested by the rapid growth of health councils, many of them linked with community councils in recognition of the interdependence of health and welfare services.

Through broad health education the public has new attitudes about disease. Scientific research has blossomed into a major industry, and the public is beginning to feel that research can solve all problems. Nutrition is recognized as valuable, and alcoholism is coming to be considered a disease rather than a social stigma.

As has happened in nearly all fields of science, social scientists are finding that as they become more experimental, their theoretical assumptions require rethinking. They are finding in the health field a wealth of opportunity for profitable investigation, and in many instances they are providing invaluable assistance to health workers. We cannot afford to ignore these important sources of assistance in health work. The all-important family unit, though retaining its primary functions of child-rearing, companionship, and the regulation of sexual conduct, has had split off from it some of its former economic and protective functions. It no longer performs the religious, recreational, and educational tasks that it once did. Many of these are now entrusted, to an increasing extent, to community agencies of one kind or another.

Meaning of Changes to Public Health

What do all of these changes mean to us who work in public health?

They mean that we need a great deal more research to be able to translate the findings of biological investigation into social application. When we meet a health problem, we must recognize that two kinds of diagnosis and treatment are necessary. We must understand and deal with the health problem. We must also understand and treat the social or public part of the situation. Our pharmacopeia in both fields must be strong. It is no longer sufficient to prescribe drugs and neglect the social factors in a given case.

These changes mean that we must enlist the support of new members of the health team. "The health team cannot be a closed circle of in-facing initiates with backs to the outside world; rather, it must be an open circle ready to welcome new workers and able to expand as new areas of useful cooperation are discovered" (2). The place of the public health social worker is becoming obvious, and there are many important functions which the various types of social scientists can perform as health team members.

We ourselves must become real people with well-adjusted lives motivated by high purpose if we are to achieve real success. The joy that comes by doing our jobs will increase as we understand them better. A major part of this understanding will need to come to us through broader knowledge of human relations and through deeper dedication to our work. We must understand our own assignments and those of our teammates as well. Our services must be made available to the family with a minimum of friction and lost motion. Overlapping and duplicating activities can no longer be tolerated. We must seek constantly to develop arrangements which the consumer can readily understand for providing health services. If there are difficulties in administration, they must be concentrated and handled centrally. We should not expect the individual patient to deal with the maze of organizations and services the modern community provides. We must accept the responsibility, as servants of the people, of working out effectively and economically our administrative problems and the problems of agency relationships.

We must do a better job of training health workers to perform their task adequately in

international relations. Our country can no longer maintain its former ostrichlike attitude; we are not self-sufficient. Our ways are not necessarily the best ways for all people. As we work with other peoples, we must adapt ourselves and our technical knowledge to their local systems and needs. We cannot be autocratic about our democracy.

With all the changes that are in the air, we as practitioners of public health have a deep responsibility and an unprecedented opportunity to serve the people. But it is only with broadest wisdom and deepest humility that we

can meet our new challenges successfully. Or in the words of Lowell:

"New occasions teach new duties; Time makes
ancient good uncouth;
They must upward still, and onward, who would
keep abreast of Truth; . . ."

To the Professional Public Health Worker

You, like the specialist in medical and other fields of science, know how important it is to be informed on current knowledge in your specialty. And, for the most part, you rely on the first-hand availability of the leading journals and periodicals in your specialty.

But as more becomes known of public health practice and research, the more complex this science becomes. There comes too the need to relate the activities of all its component disciplines—the members of the family of public health—one to the other, and each to the whole. And for each specialist there is a need to read regularly the journals devoted to unifying the family of public health. *Public Health Reports* is such a journal.

A Method of Simplifying Soil Percolation Tests For Septic Tank Systems

By ABRAHAM GELPERIN, M.D., Dr.P.H.,
and WILLARD O. FULLER, B.B.A.

Cities and towns are facing anew the recrudescence of an old and presumably solved problem—sewage disposal. This problem is particularly acute in fringe areas where there have been marked population growths during the past decade (1).

The mushrooming of new residential and industrial building beyond the limits of common sewage disposal services, both inside as well as outside corporate limits, has led to present and latent health hazards. This state of affairs is of pressing interest to health officers as well as sanitary engineers. Municipal sewage systems, with either new or expanded treatment facilities, are costly. However, long-range planning for the metropolitan area, if possible, is considered to be the least expensive and most efficient procedure (2). Extension of facilities street by street, as neighborhoods petition city councils, is an expediency only. For the health officer this situation entails resolving the results of inadequate past control of individual and area sewage disposal. The rules and regulations needed to insure adequate sewage disposal for the present and future must be promulgated as well. The permanent solution to the backlog of sewage disposal nuisances is extension of present common sewage disposal facilities or initiation of a sanitary district (1-3).

Soil Percolation Test

But of immediate import is the approval by the health department of all buildings that re-

Dr. Gelperin is director of the Des Moines and the Polk County Health Departments and Mr. Fuller is chief of the bureau of environmental hygiene of the departments.

Automatic soil percolation timer.

quire private sewage disposal, since minimum standards for private sewage disposal systems are a part of State regulations and statutes. One important aspect of this method of control, measuring the water absorption capacity of soil, continues to be a time consuming and thus a costly although necessary procedure. There is general agreement that the determination of the porosity of the soil that is to receive septic tank effluent, in conjunction with other factors such as probable sewage load, land slope, water table level, land area, and water supply, is mandatory in order to insure adequate disposal of the effluent (4, 5). However, the present technique of watching water seep out of a hole in the ground is frequently prohibitive in cost to many health departments, for sanitarians performing such tests cannot perform their other manifold and necessary environmental health services.

It is not pertinent here to discuss the dynamics of the absorption of water by soil. However, reasonably accurate criteria for the efficient and safe disposal of septic tank effluent in a tile field have been evolved, based upon soil percolation tests and the other factors mentioned above (4, 6). The area of a tile absorption field is the minimum required for the probable maximum sewage load.

Field experience has shown that soil percolation tests in one disposal field as well as in adjacent building sites may vary markedly (7). In fact, our present technique is to make at least four soil percolation tests for each field disposal area; each test hole is 8 inches wide and 27 to 30 inches deep. The results of such tests in just one Des Moines real estate development of 30 adjacent lots, requiring septic tank sewage disposal systems for 2-3 bedroom houses, illustrated the variability of soil water absorptive capacity in a relatively small area. The lots, each with a 100-foot front by 200 feet deep, were on rolling pasture land with a Webster soil as determined by a geological survey. The feet of tile required in a trench 18 inches wide by 30 inches deep is given below for the various lots.

<i>Feet of tile required</i>	<i>Number of lots</i>	<i>Percent</i>
144 (minimum)-----	0	0
162-198-----	10	33
211-299-----	9	30
300-399-----	7	23
403-480-----	4	14

This is but one example which emphasizes the necessity of soil porosity tests even for adjacent building lots.

Automatic Timing Device

A drawback to the soil percolation test, watching water seep out of a hole in the ground, has been satisfactorily solved by the use of a simple, inexpensive, automatic timing device. The instrument was constructed by our director of the bureau of environmental hygiene and has had a year of field test to date, verifying its accuracy and ease of utilization. The timers can be set up in a few minutes. The sanitarian can then leave the test fields to perform the other functions of a sanitarian. He returns in the late afternoon to pick up the timers and record the percolation times.

A total of 408 absorption fields for 2-3 bedroom houses scattered throughout Des Moines have been tested during the past year, and the following table presents our results, utilizing an automatic soil percolation timer.

<i>Total time needed for 6 inches of water to percolate (minutes)</i>	<i>Number of tests</i>	<i>Average time required for percolation (hours)</i>	<i>Feet of tile required</i>
24	0	0	144
30-60	126	95	162-198
66-120	115	178	211-293
126-240	88	264	300-399
246-360	55	275	403-480
>360	24	144	refused
	408	956	

It is considered that approximately 956 man-hours have been saved by utilizing an automatic timing device, since the time required to set up the devices for the percolation tests is not appreciably longer than preparation for the tests used in present practice. We have had no problem of tampering with the device for several reasons. We know from geological survey data (7) the types of soils in the area and, roughly, their absorptive capacities. The health department program of prevention of septic tank sewage disposal malfunction has been coordinated with interested groups such as the home builders association, real estate board, master plumbers association, zoning boards, mortgage and loan associations, and public officials. Community groups have also been alerted to the available public health service. An intensive educational campaign is a mandatory requirement.

Construction

The percolation timer, constructed of aluminum, consists of a base plate that will rest over any size percolation hole and has legs that will adjust the base to a horizontal position. On the plate is a rugged clock that fits snugly against the stops on the plate. To its rear is the trip mechanism which stops a sprocket wheel when the trigger arm is depressed. The clock has a housing to protect it from rain. The ruler post is fastened upright when in use, and the bottom of the ruler is set at the same height as the top of the trigger arm. The clock is set at noon; the float which has been inserted through the sleeve is assured of free movement by leveling the base. The round tripping ring is screwed tight at the point on the float rod opposite the top of the ruler, thus

setting the mechanism to automatically trip the trigger when 6 inches of water have been dissipated from the test hole. It is seen that the fall of any water column height can be automatically timed. The float is a cellulose compound and standard equipment as a water closet float. With this mechanism, two extra inches of water are used to compensate for water-swollen earth on the bottom of the test hole as well as the level of the float below the surface of the water column, a total of 8 inches of water. Presoaking the test holes 12 hours before the tests is a part of the routine. The reasons for this latter part of the procedure have been adequately presented elsewhere (5, 8, 9).

This automatic percolation timer permits a health department to perform accurate soil percolation tests in many more areas than possible with the present technique. It adds to the officialness and thus the acceptance of the percolation time as an important adjunct to the planning for private sewage disposal systems. And most important, the timer permits health department environmental sanitation personnel to resume other environmental health service functions.

Federal Food and Drug Laws Violated

The Food and Drug Administration of the U. S. Department of Health, Education, and Welfare reported 119 seizures of food and drug shipments during April 1953. All were civil actions to remove products from the market before they reached the consumer.

One permanent injunction and 27 fines against individuals and firms were also reported during April. One of the fines, \$850, was imposed against an unlicensed operator of a treatment center in Kentucky. Through a "runner" in St. Louis, he supplied worthless herb medicines for out-of-State use to patients, mostly from midwestern States, whom he had diagnosed without physical examination. Several appellate courts have ruled in similar instances that the Federal Food, Drug, and Cosmetic Act is violated when misbranded medicine is offered for interstate transportation even though the "doctor" did not make the shipment.

Establishment of definite responsibility for violating the Federal food and drug laws may mean criminal prosecution for the alleged violator, the Food and Drug Administration has warned.

1952 Summary of Foodborne, Waterborne, and Other Disease Outbreaks

By C. C. DAUER, M.D.

IN ADDITION to reporting cases of specified notifiable diseases, State and Territorial health officers are requested to report promptly all outbreaks or unusual occurrences of communicable and other diseases of public health interest. These specifications are a part of the national morbidity reporting system which has evolved through trial and modification. Its most recent revision was unanimously approved by the Association of State and Territorial Health Officers in October 1951, effective January 1, 1952 (1).

Purpose of Epidemic Reporting

The reporting of disease outbreaks is parallel and complementary to the weekly and annual reporting of cases. Whereas reporting of cases provides the data necessary to develop the incidence rates of diseases, which indicate changes in the relative magnitude of disease problems and the resources that should be allocated to control them, epidemic reporting emphasizes the circumstances of specific outbreaks. Its purpose is not so much to count every case but rather to find, through field epidemiological investigation, the sources and vehicles of infection and, if possible, the specific organism involved.

For purposes of controlling disease, it appears more important to know, for example, that

the cook in a summer camp where an outbreak of typhoid fever occurred was discovered to be a typhoid carrier, or that infection was definitely traced to a polluted well, than that 20 rather than 10 cases occurred.

More specifically, investigation of foodborne outbreaks in 1952 repeatedly showed that the importance of properly storing and refrigerating food and of food handlers keeping their hands clean was not appreciated. It follows that expensive restaurant equipment and complicated licensing arrangements seem to be less significant in controlling disease than compliance with relatively simple measures. Food stored promptly in an inexpensive icebox is less likely to spoil than food placed in the most elaborate refrigerator after a few hours' exposure at room temperature. Thus the qualitative details developed in epidemic reports are essential for pointing the way to specific control measures in States and communities. Prompt reporting of unusual occurrences of disease and the circumstances surrounding them are of special importance at the present time as a defense measure against the threat of biological warfare or other catastrophe.

Scope of the Summary

In keeping with the purposes outlined above, this report has been made as extensive as possible. It summarizes all outbreaks and unusual occurrences of disease, with specific exceptions noted below, considered important by the reporting health officers during 1952. This represents a disease base somewhat broader than was

Dr. Dauer is medical adviser to the chief of the National Office of Vital Statistics, Public Health Service.

used in previous outbreak summaries, which were restricted to foodborne and waterborne diseases (2).

Some of this extension was made possible by the addition to the lists of notifiable diseases, on January 1, 1952, of certain diseases not previously reportable on a national basis. Infectious hepatitis, for example, was mentioned in only 2 or 3 reports during 1951; its addition in 1952 apparently focused attention on its widespread occurrence and led to the reporting of 27 outbreaks. This beginning makes it possible to include the disease in the present summary, though it is obvious that in view of the 17,200 individual cases reported full reporting of infectious hepatitis outbreaks was far from being achieved.

Various other diseases, such as ringworm of the scalp and rickettsialpox, which are not specifically included in the lists of those to be reported to the Public Health Service, are nevertheless reportable in many States. To the extent that such reports were forwarded, they are included in this summary for the first time.

In certain instances, information on an outbreak was first obtained from other Federal agencies. For example, a widespread outbreak of salmonellosis in infants, due to ingestion of infected dried egg yolk, was discovered by the Food and Drug Administration. This exchange of information, resulting from cooperative arrangements, is of mutual benefit to the various agencies concerned.

The outbreak of influenza B early in 1952 is not included because it has been described by the Influenza Information Center, National Institutes of Health (3). Although certain other diseases, notably poliomyelitis, occur in localized epidemics, they are excluded because it is not practicable to report them as outbreaks.

Details of nearly all the individual outbreaks covered in this report have appeared currently in the Communicable Disease Summary issued weekly by the National Office of Vital Statistics.

Limitations of Reporting

The tabulation of outbreaks in the accompanying tables shows very clearly that reporting practices differ widely from State to State. The large number of outbreaks reported by some

States as compared with small numbers or none at all in other States undoubtedly reflects superior reporting practices more than differences in occurrence. In many parts of the country the importance of reporting, investigating, and applying control measures to epidemic diseases is evidently not adequately understood. In some States little effort has been made to overcome the considerable time lag in reporting by physicians and local health departments. In others a vigorous promotion effort seems necessary in order to get any reports at all. This problem of overcoming the difficulties in getting unusual disease situations reported, so that investigations may be made, is of concern not only to the Public Health Service and the State health departments, but to the Food and Drug Administration and the Department of Agriculture, and to analogous agencies in State governments.

Figures on numbers of outbreaks, and particularly on numbers of cases, as shown in the tables, should therefore be regarded as indicative of conditions in States with well-developed reporting systems, rather than as a basis for interstate comparisons. Even in States with the most alert reporting systems, the exact cause of outbreaks is sometimes impossible to determine because specimens for laboratory examination cannot be obtained.

Summary of Findings

Outbreaks of waterborne and milkborne diseases in 1952 were confined to a few States, but outbreaks in which food other than milk was the vehicle of infection occurred in all parts of the country. Faulty methods of handling food and improper storage and refrigeration continued to be found on investigation of many outbreaks. These defects were also evident in the reports of outbreaks in 1951 (2).

Despite progress in sanitation and other health measures, there are many persistent communicable diseases that continue to challenge health authorities. For example, staphylococcal food poisoning, salmonellosis, bacillary dysentery, and many diarrheal diseases of unknown etiology remain as common occurrences, and infectious hepatitis appears to be on the increase.

Vehicle of Infection

Water

A somewhat larger number of waterborne outbreaks of disease was reported in 1952 than in 1951, but the number of persons involved (530) was smaller in 1952.

In one outbreak, well water which became polluted as the result of a blocked sewer was the vehicle of typhoid infection; in another, a dug well supplying water to a restaurant was considered to be the source of typhoid infection. Three other outbreaks of typhoid fever were suspected of being waterborne, but definite proof was lacking.

A large outbreak of infectious hepatitis occurred among persons attending a summer camp in which spring water was shown to be polluted. Three weeks prior to the onset of the hepatitis cases, an outbreak of gastroenteritis had occurred among this group. Eight other outbreaks of undifferentiated gastroenteritis were reported in which water was considered to be the vehicle of infection. Five of these involved the use of polluted wells; one was traced to the use of raw creek water; and in another, low water pressure had permitted water fountain outlets to become contaminated.

Milk and Milk Products

Comparatively few of the outbreaks reported in 1952 were traced to milk or milk products. One milkborne outbreak occurred in an institution which used raw milk produced on the premises. *Streptococcus faecalis* of the viridans group was recovered from the milk. A large epidemic of *Shigella sonnei* dysentery occurred in a school using milk from a dairy. Investigation showed that a batch of milk at this dairy was improperly pasteurized immediately preceding the outbreak, but the source of infection of the milk was not determined. In another instance, milk was only suspected of being the vehicle of infection of a group of 100 cases of gastroenteritis in a school.

Milk products were found to be vehicles of infection in only three small outbreaks of disease. One group of 5 persons became ill after eating cheese; another, of 10 persons, after eating ice cream contaminated with *Salmonella montevideo*; and the third, of 7 persons, after

Foodborne and waterborne disease outbreaks, by vehicle of infection, reported in 1952

¹ Reported from ship in port city.

drinking eggnog from which a *Salmonella* organism was isolated.

Poultry and Eggs

Poultry and eggs were far more important than milk or water as sources or vehicles of infection. In 39 outbreaks, a large proportion of which were proved or suspected to be *Salmonella* infections, chicken or turkey, more often the latter, were proved or suspected to be the vehicles of infection. In a disease outbreak in a family group, eggnog was found to contain a type C *Salmonella* organism, and *Salmonella* infections in infants in many parts of the country were traced to a powdered egg yolk product. These reports very clearly indicate that fowl and eggs constitute a large reservoir of infection, and they emphasize the need for more effective measures to prevent transmission of infection to man.

Shellfish

Only one outbreak of 66 cases was reported in which raw shellfish were consumed. There was no definite proof of contamination of the raw clams eaten at a country club dinner, but no other source of infection for the outbreak could be found.

Types of Infection

Staphylococcal Food Poisoning

Laboratory evidence of the presence of a staphylococcus in food was available for 32 outbreaks of food poisoning, and epidemiological investigation indicated this type of food poisoning in 45 additional outbreaks. Of these 77 outbreaks, a cream-filled pastry was involved in 15; ham, in 21; turkey or chicken, in 10; and salads, in 10.

In 28, or approximately one-third of the 77 outbreaks, lack of or inadequate refrigeration was considered to have been a contributing factor. In 5, a food handler was found to have lesions or infections on his hand; in 3, a food handler had a throat infection; in 4, foodhandling procedures were considered unsatisfactory; and in 1, a dirty meat grinder was considered to have been the source of contamination.

These outbreaks were distributed as to place of occurrence or source as follows: schools and institutions, 26 percent; public eating places, 25 percent; banquets and picnics, 19 percent;

homes, 15 percent; and following purchase of food from bakeries, 15 percent.

Typhoid Fever

Eleven outbreaks of typhoid fever, consisting of 152 cases, were reported from 5 States in 1952, as compared with 3 outbreaks in 1951. In four instances, carriers, not previously known, had prepared food eaten by persons who became ill. In one of these occurring in a day camp, the camp cook was discovered to be a carrier through an examination of food handlers. Water was suspected of being the vehicle of infection in two outbreaks, but bacteriological evidence was lacking. Contaminated well water was shown to be the source of infection in two other outbreaks, and the use of polluted river water was demonstrated in another. In one family outbreak, no source of infection could be found. Milk was not suspected of being the vehicle in any typhoid fever outbreak.

Bacillary Dysentery

One of the 12 reported outbreaks of bacillary dysentery, or shigellosis, was considered to be milkborne, but none waterborne. These outbreaks, consisting of 1,441 cases, resulted in 13 deaths. In the milkborne outbreak, consisting of 639 cases in a school, epidemiological investigation revealed that pasteurization had been improperly carried out, but the source of infection of the milk was not discovered. One outbreak of 36 cases and 12 deaths in an institution was considered to be a person-to-person type of infection. Two outbreaks were considered to have been transmitted by food other than milk—in one instance, a tuna fish salad.

In 9 of the 12 outbreaks, *Shigella sonnei* type of infection was demonstrated, and a Flexner type of *Shigella paradysenteriae* was found in the remaining 3.

Salmonellosis

Outbreaks of salmonellosis in 1952 were reported to have occurred under a variety of conditions, namely, in a nursery for newborn infants; following banquets, church suppers, and picnics in institutions and schools; in a jail; in private homes; and often following eating in restaurants. In 15 outbreaks, consisting of 597 cases and 2 deaths, *Salmonella* organisms were identified as follows: *S. typhimurium*, in

7; *S. oranienburg*, *S. heidelberg*, and *S. newport*, in 1 each; and an organism in group C, in 2. Five of these outbreaks followed ingestion of turkey or chicken meat, and in one, homemade eggnog was presumed to have been contaminated by raw eggs.

Sixteen other outbreaks, involving 738 cases, were reported in which laboratory confirmation of the diagnosis was lacking. In 14 of these, turkey or chicken meat was regarded as the vehicle of infection; 1 occurred in a nursery; and in the remaining 1, barbecued beef appeared to be the vehicle.

In addition to these outbreaks, cases of salmonellosis among infants with a history of ingestion of dried egg yolk were reported from many parts of the country. Early in November it was recognized that a few cases followed the ingestion of dried egg yolk processed by a single manufacturer. The first so recognized was in the District of Columbia, and soon after suspect cases were found in New York City. Presence of *S. montevideo* was demonstrated in the stools of sick infants and in samples of certain code numbers of the egg product. All State health officers were then notified to investigate and report any cases of salmonellosis coming to their attention. Contamination of the dried egg yolk was demonstrated throughout the whole range of production, which began about the middle of 1952. Sale of the product began in July and all unsold supplies were recalled in November.

Laboratory confirmation of diagnosis was obtained in over 50 such cases in 16 States and the District of Columbia. In an additional 40 cases laboratory evidence of infection was not mentioned in the report. These *Salmonella* infections were predominantly *S. montevideo*, but *S. barielly*, *S. oranienburg*, and *S. tennessee* were also reported. Nearly all cases were reported to be mild and there were no deaths.

Undifferentiated Gastroenteritis

In 50 outbreaks of disease, there was insufficient information to determine the type of infection. In 8 of these, water was considered to be the source of infection. In 1 outbreak, where creek water was used as drinking water, "a good many" cases were reported. In 2 outbreaks, 50 persons became ill after drinking water from

wells, investigation of which disclosed seepage from septic tanks; and in 2 others, faulty chlorination had preceded the outbreak.

Trichinosis

Five outbreaks of trichinosis were reported in 3 States. In 3 of the outbreaks, the patients had eaten partially cooked or uncooked pork, and in the fourth, 7 of 9 persons who had eaten bear meat developed symptoms 14 to 17 days after exposure. The bear meat had been in cold storage 10 days and then frozen.

Botulism

Only 2 small outbreaks of botulism were reported in 1952, 1 in California and 1 in Oregon. In one, in which 3 persons were ill and 2 died, home-canned mushrooms were involved. In the other, involving 2 persons, both of whom died, home-canned beets were found to be contaminated. Both groups of cases were caused by botulinus toxin type A.

Streptococcal Infections

Five outbreaks of streptococcal infection were reported, 4 of them involving 359 cases and no deaths and the fifth involving a "communitywide area." Epidemiological investigation of one group of 82 cases, which occurred in a hospital, indicated that the outbreak was foodborne, but the specific item of food was not identified. An outbreak in an institution for boys, in which 62 of 195 persons exposed developed the infection, was traced to a viridans type of streptococcus in raw milk. A group of 81 cases of streptococcal sore throat was reported among persons who had eaten warmed-over stew in a college dormitory dining room, which served about 600 persons. *Streptococcus viridans* was isolated from the purulent discharge from the thumb of a cook and from throats of the ill persons.

Outbreaks in Military Personnel

Sixty-nine disease outbreaks were reported in various units of the armed services stationed in continental United States in 1952. A total of 3,833 persons were affected. Thirty-seven, or more than half, of these outbreaks, were classified as food poisoning. One outbreak, involving 78 persons, was identified as bacillary

dysentery. Six, involving an unknown number of persons, were shown to be *Salmonella* infections. Others were reported merely as diarrhea or gastroenteritis. None of these outbreaks are included in the data given in the accompanying tables.

Other Disease Outbreaks

A number of disease outbreaks not attributed to food or water were also reported during 1952. These included diseases spread by person-to-person contact and those in which animals or arthropods were the source of infection.

Infectious Hepatitis

Outbreaks of infectious hepatitis reported in 1952 numbered 27. The 1,306 cases in these outbreaks, however, represent only a small fraction of the 17,200 cases reported in weekly telegraphic reports. The numbers reported in the outbreaks varied from a few to 200. Several of these outbreaks occurred predominantly in school populations or among college students; 2, in summer camps; 3, in housing developments; and 2, at Indian reservations or schools. Person-to-person contact was considered to be the principal mode of transmission. However, in one outbreak occurring on an island, nearly all persons affected were users of the same water supply. Another outbreak of 104 cases among persons attending a church camp was preceded by an epidemic of gastroenteritis. In this instance, it was clearly demonstrated by use of a dye that the spring water supply of the camp was contaminated by a leak in the sewer line from one cottage.

Diphtheria

In spite of the fact that diphtheria has shown a steady decline in incidence for many years, 8 outbreaks with 269 cases and 6 deaths were reported in 5 States and Territories in 1952. One small outbreak at an Indian reservation was characterized as an occurrence of "black" diphtheria. Seven cases with two deaths occurred in an institutional outbreak. One outbreak of 64 cases was confined to a single area of a city, and another was believed to have occurred because medical services provided in the community had emphasized curative rather than preventive measures.

Psittacosis

Several family outbreaks of psittacosis were reported. Two outbreaks of 3 cases each followed contact with sick parakeets in the home; another involved 2 persons. Outbreaks of the disease were also reported among workers in a poultry processing plant, and a group of three cases occurred among railway express employees who had contact with psittacine birds being shipped. Investigations indicated that pigeons and canaries were sources of infection of individual cases reported in various parts of the country.

Miscellaneous Diseases

Anthrax was reported in a large number of domestic animals, mostly swine, in the north central States early in 1952. Contaminated bonemeal was found to be the vehicle of infection. Two cases in humans for whom there was a history of contact with diseased animals or with the contaminated feed, and a number of cases in animals following vaccination against the disease were also reported.

Twelve cases of tularemia occurred in a family group as the result of contact with a wild rabbit. An outbreak of rickettsialpox occurred among persons living in an apartment, investigation of which revealed large numbers of house mice and mouse mites in the vicinity of the apartment incinerator.

Other outbreaks reported included ringworm of the scalp in a group of school children, encephalitis in the central valley of California, several groups of cases in which Cocksackie virus was regarded as the probable infectious agent, a small group of malaria cases in children attending a summer camp, trachoma at an Indian reservation, and a group of cases diagnosed as primary atypical pneumonia in an institution.

Protozoans in Stools

Unpreserved and Preserved

In PVA-Fixative

By MORRIS GOLDMAN, Sc.D., and
MARION M. BROOKE, Sc.D.

In an earlier report (1), we demonstrated the effectiveness of polyvinyl alcohol (PVA) fixative in preserving the trophozoites of the intestinal amebas and recommended that it be incorporated in a two-bottle outfit for the collection of stool specimens whenever it was not possible to have them examined immediately. This method of collection is particularly applicable to public health laboratories which generally receive specimens for diagnosis through the mail. The present study compares the relative effectiveness of the PVA-fixative technique and other procedures in detecting intestinal protozoans in feces.

Materials and Methods

Arrangements were made with the Grady Memorial Hospital in Atlanta whereby stool specimens were collected and sent to the Communicable Disease Center laboratory of the Public Health Service in Atlanta for examination. Part of each normally passed, fresh stool was immediately preserved in PVA-fixative, and a part was left unpreserved. All specimens were over 4 hours old when they reached the laboratory.

Patients submitting stools included new hospital admissions and individuals suspected of having amebic or other intestinal infections. Five hundred specimens were submitted from approximately 270 patients. Since the specimens were generally identified only by the pa-

tient's last name, it was not possible to tell in every instance whether the patient was a repeat case or a new one. For these reasons, the percentages of the parasites found in this study do not indicate infection rates of a population. They represent only what was found in 500 separate stool specimens examined by various techniques.

Examination

The unpreserved portions were examined by direct wet mounts (saline and iodine), modified zinc sulfate concentrations, and hematoxylin-stained direct smears, the methods for which are described in techniques 1, 2, and 3 below. The PVA-preserved portions were examined by hematoxylin-stains of PVA films, as explained in technique 4.

Technique 1. A fleck of feces was mixed with a drop of saline and covered with a 22 mm. square cover slip. A similar preparation was made using an iodine solution. The entire saline mount was carefully examined. The iodine mount was used to assist in identifying organisms which were found in the saline preparation.

Technique 2. Approximately 1 gm. of feces was mixed with tapwater in a 14 by 85 mm. test tube. The test tube was centrifuged at 2,000 r. p. m. for 1 minute. The supernatant was poured off, and the tube was refilled not quite to the top with zinc sulfate solution (specific gravity 1.18). After a second centrifugation at 2,000 r. p. m. for 1 minute, the tube was placed on a rack, and sufficient zinc sulfate solution was added with a dropper to raise the meniscus above the top of the tube. A 22 mm. square cover slip was carefully superimposed on the tube and allowed to remain undisturbed for 5 to 10 minutes. At the end of that time, the cover slip was removed, lowered onto a drop of iodine solution on a slide, and examined.

Technique 3. Flecks of feces were spread in thin films on two 75 by 25 mm. slides, which were immediately immersed in Schaudinn's fixative. One slide was then stained by the Tompkins-Miller rapid hematoxylin technique (2). When the results of this method were not criti-

Dr. Goldman and Dr. Brooke are the respective chiefs of the intestinal parasitology laboratory and the parasitology-mycology section of the laboratory branch, Communicable Disease Center, Public Health Service, Atlanta.

Table 3. Number of identified infections found by various combinations of techniques

Combination of techniques	<i>Endamoeba histolytica</i>		<i>Endamoeba coli</i>		<i>Endolimax nana</i>		All species	
	Number	Percent	Number	Percent	Number	Percent	Number	Percent
Unpreserved portions (techniques 1, 2, and 3)-----	27	71	32	82	44	62	117	66
Hematoxylin-stained PVA film-----	28	74	25	64	67	94	146	82
PVA-fixative plus direct wet mount-----	28	74	33	85	68	96	156	88
PVA-fixative plus modified zinc sulfate concentration-----	33	87	39	100	70	99	169	95
PVA-fixative plus hematoxylin-stained direct smear-----	33	87	29	74	70	99	160	90
All 4 techniques-----	38	100	39	100	71	100	178	100

sulfate methods would appear to be the most efficient combination of techniques. With these 2 methods it was possible to find 95 percent of the identified infections found by all 4 methods (169 of 178). The other 2 combinations—PVA-fixative plus hematoxylin-stained direct smears and PVA-fixative plus direct wet mounts—revealed 90 and 88 percent, respectively, of the total infections identified.

Unidentified Organisms. Of 16 cases where organisms were seen but were not specifically identified in the PVA-fixed portions (table 1), 12 (75 percent) were trophozoites. In most cases, these were *Endamoeba* organisms which could not be diagnosed definitely as either *histolytica* or *coli*. In our experience it has been impossible to identify specifically a proportion of *Endamoeba* trophozoites in stained preparations on the basis of the classic descriptions of the two intestinal species.

Since, in this study, the unpreserved specimens were several hours old when examined, the organisms not identified by the other techniques were mostly rare distorted cysts or degenerated trophozoites. When the resources of all 4 techniques were used, the number of organisms not identified was 15 compared to 178 identified, or 8 percent of all organisms seen.

Summary

Five hundred normally passed stool specimens were divided into two portions immediately after passage. One portion was left un-

preserved; the other was preserved in PVA-fixative. The unpreserved portions were examined by direct wet mounts, zinc sulfate concentrations, and hematoxylin-stained direct smears. The preserved portions were examined by hematoxylin stains of PVA films. All examinations were performed no sooner than 4 hours after the stool was passed.

The PVA-fixative portions revealed more infections with protozoans than did all 3 other techniques combined, mainly as a result of the preservation of trophozoites. Trophozoites were found in 63 percent of all infections detected and in 59 percent of the infections found in formed stools. This suggests that it is advisable to preserve both formed and soft stools in PVA-fixative. The combination of the PVA-fixative method (for trophozoites) and the zinc sulfate method (for cysts) demonstrated more infections than did any other combination of 2 techniques used in this study.

Technical Assistance for Public Health

In the Republic of Indonesia

By E. ROSS JENNEY, M.D., M.P.H.

DESPITE the magnitude and complexity of public health problems in Indonesia, to conclude that the great need depicted there indicates, a priori, a corresponding scope for technical assistance would be a mistake. A sudden catastrophe in a highly organized society will utilize relief in direct proportion to need; but a socioeconomic dilemma developing over the centuries, like that which does exist in Indonesia, is probably of such a character as to limit sharply the fulfillment of its most desperate requirements.

The generalization may even be made that under these circumstances the capacity of an underdeveloped area to absorb technical assist-

ance is inversely proportional to its need. Therefore, the corrective effort chosen should not precipitate a host of new problems by creating an unreasonable demand for housing, power, roads, transportation, interpreters, and the like. Regardless of the need and the amount of available aid, the vital measure of what can be done is the absorptive capacity of the area.

Need for Foreign Assistance

An extraordinary number of surveys in the public health field have been made in Indonesia by a variety of agencies and individuals. Indonesian officials have reached the saturation point in the number of ideas which they can receive as to what should be done, and they are understandably skeptical about new proposals. Actually, the need for foreign assistance is fully recognized, and the Government is availing itself of aid proffered by the United Nations agencies, Technical Cooperation Administration, and other organizations.

Since foreign assistance and local capacity to absorb technical assistance are both perforce small in relation to the need in Indonesia, a big task falls on the shoulders of those who are guiding technical assistance and upon the Indonesian officials who are responsible for devising its efficient application. Measures of need in the form of surveys are necessary, as are estimates of indigenous resources, but the actual problem in Indonesia is to select a point of beginning, to choose an open avenue of approach which will not prove to be an ultimate dead end.

Introductory to understanding the health problems of Indonesia and the difficulties of administering technical aid in Southeast Asia is Dr. Jenney's background report on "Public Health in Indonesia" in the April 1953 issue of Public Health Reports (p. 409).

A commissioned officer in the Public Health Service, Dr. Jenney was assigned for 2½ years to the Technical Cooperation Administration (TCA) Mission to Indonesia as chief of the public health division. Dr. Jenney's current assignment has taken him to Santiago, Chile, as chief of the health and sanitation field party of the Institute of Inter-American Affairs.

Another aspect of technical assistance in Indonesia—in this instance the special problems encountered in two rural polyclinics in Middle Java—is described by Warren A. Ketterer on p. 558 of the June issue.

The need for technical assistance in Indonesia in the public health field does not differ basically from the need for more outright economic aid. During the 3½ years of Japanese occupation in World War II and during the subsequent struggle for independence, public health facilities on the group of islands deteriorated. Technical health personnel were lost to the islands because of the exodus of many of the Dutch. The same is true of agriculture, engineering, and mining: everywhere there is a shortage of tools and of those who know how to use them. A rapidly increasing population progressively accentuates these deficiencies, and a preoccupation with the complexities of new sovereignty and its political implications of hope and of disappointment compromises the effectiveness of remedial measures.

This preoccupation is exasperating to all those whose technical talents and professional thinking were developed in an environment of economic, social, and political stability. But the preoccupation is real, and it is not to be overridden by any plan of proffered assistance which does not recognize and sympathize with the fact that Indonesian Government officials are all filling dual and triple positions, each position enmeshed with a complexity of political and administrative issues. Eager to utilize either the short-range impact value or the long-range economic value of any project, the Indonesian Government is examining every opportunity to lessen the disappointment of the country in discovering the initial problems of independence.

The reaction which a given community may develop as a consequence of receiving a service previously unknown is somewhat irrelevant to the actual situation confronting the Indonesian Ministry of Health. Indonesian officials are naturally impatient with schemes which introduce a new service in a limited sphere while the major issue of rehabilitating former services remains unaffected. This attitude does not mean a condemnation of a scheme per se but simply an impatience with its irrelevancy at this time. When the load is heavy, foreign assistance should add another horse rather than another cart.

The large rural population of Indonesia is relatively stable, and its stability is based on the

subsistence-level individual farmer. The people are illiterate, patient, intelligent, and receptive, but not reactive. They harbor guerrillas, but they do not mobilize armies; they absorb ideology, but they resist the call-to-arms phase of propaganda. The rural population has a keen desire to participate in new developments which may improve its economy, regardless of the source, but it likes to feel the impact of such developments through its own Government. However, many areas seem to have a natural taste for local autonomy.

The indications are that the rural recipient of technical assistance is being and will be reached by assistance which is channeled through the Ministry of Health. Reaction which redounds through official health channels is far more effective in the long run than reaction which develops from assistance dropped, as from a parachute, to an isolated rural community.

Choice of Approach

The task of national planning in a situation such as prevails in Indonesia is new. Only recently has public health advancement in a large underprivileged population been considered as the full responsibility of an indigenous government. The task requires a different orientation from that evolved by colonial governments, missionary organizations, and the like. The task of national planning comes at a time when new insecticides and new drugs have changed the mechanism of disease control projects and at a time when global air transport facilitates rapid interchange of technical personnel. Most important, it follows at the heels of the "awakening of Asia."

The situation in Indonesia has certain distinct features which accentuate or modify the health picture, making it somewhat unique. Geographically, the Republic of Indonesia is the most complex nation on earth, and this complexity accentuates the logistics of transportation and communication. Its health services, although qualitatively good, are quantitatively perhaps the most deficient of any nation. Indonesia also faces a rather formidable language problem, since its secondary language—Dutch—is of limited use in general interna-

tional contacts. This forces the Indonesians to make special effort to speak English and creates a demand in many Government departments for English-speaking officials, many of whom are leading physicians and surgeons withdrawn from their medical activities by the Government.

With trained personnel and funds so scarce in relation to the need, the choice of the most expedient approach to meeting the need cannot be influenced by prejudices previously formed in an atmosphere of affluence. Those who have faced decisions in similar situations will agree that it is not an easy concept to keep constantly in mind. The age-old puzzle presents itself: which dollar is the most expedient in a given situation—one, the dollar spent in economic improvement with its consequent effect on health and education; two, the dollar spent on education with its effect on health and economics; or three, the dollar spent on health to provide manpower for economic development and sound minds for education?

Question of Emphasis

This choice of accent assails the planner at every step whether he is thinking in terms of the entire nation or of a single village. It will be a long time before there will be the human and financial resources in Asia to allow a simultaneous approach to all three avenues on an adequate scale. Occasionally, the choice is easy, but centuries of failures throughout world history give evidence that the weak spot in the eternal cycle of ignorance, poverty, and disease has been recognized by hindsight more readily than by foresight.

There are areas in Indonesia which have been drained of their best intellects because education provided opportunity for better reward elsewhere. One of the most poverty-stricken areas, with an infant mortality of 53 percent, is paradoxically one of the most literate areas. The failure here was perhaps because education was at an academic level, neglecting the more basic local needs at the trade school or agricultural school level.

Again, obvious failures can be seen in the transmigration areas of Sumatra and Celebes to which Javanese farmers were transplanted.

Some of these transmigrations resulted in tragic debacles because of malaria, which should have been the first consideration. Consequently, the elaborate economic preparations—and even educational and clinical facilities—proved to be expensive and futile plans, defeated by the overlooked mosquito. The abandoned paddies remain as monuments to the oversight.

Trend of Foreign Assistance

All issues which have given rise to a need for technical assistance in Indonesia are influenced by either one of two factors. One of these is the underdevelopment of resources. Another very different factor is the deterioration of what has already been developed. The former is too extensive to measure—the need can only be identified; it is immeasurable in relation to present capacities to meet it. The latter—deterioration of what has been developed—is measurable and therefore is useful in planning; it can be weighed against existing capacities to correct it with available assistance. The rehabilitation of a worthwhile but deteriorating health facility is a tangible and sound objective. In Indonesia, there is ample opportunity in this field because of the framework of public health facilities instituted under the Dutch but severely depleted during World War II and because of the subsequent period of protracted military action.

This deterioration, which leads to a disappointment to Indonesia as it first experiences freedom, is only part of a general progressive decline in many fields other than public health. The restitution of public health services has an advantage in that it is not fraught with the quandaries encountered in the economic field, such as the feasibility of rebuilding a sugar mill in the face of doubtful markets.

In the health field in Indonesia, technical assistance, supplies, and equipment from outside agencies are being devoted to (a) major disease control projects which introduce effective methods and which are administratively feasible under the present circumstances, particularly in yaws and malaria; (b) educational projects in professional and subprofessional medical fields and in popular health educa-

tion; (c) the support of certain indigenous preventive programs selected partly because they are in a position to utilize assistance to full advantage and to continue in the future; and (d) emergency items to replenish depleted medical services.

Psychological Aspects

Many devices have been used to illustrate the conflict arising when a conventional Eastern mind meets a conventional Western mind. In this day of airborne technicians and consultants, the conflict has a new meaning in terms of its potentiality for wrecking plans. A necessary part of planning, therefore, is the consideration of the tendencies of the East to misinterpret Western methods and of the West to overestimate the applicability of these methods. In the past it has been possible for the various agencies on encountering this conflict to allow time for adjustment and to select men of experience who were prepared to dedicate a substantial portion of their lives to reach an understanding with the Eastern mind. During the last few years, however, countless Western technicians have been sent to the East and have been given perhaps no more than a few days to establish a liaison which history has proved to be difficult to obtain in years. To these men it is a matter of desperate necessity constantly to check their own prejudices, of which they may have been unaware, and the prejudices of the East, which Eastern officials by virtue of courtesy and restraint do not reveal at once.

The newly arrived Western technical expert will be disappointed if he places too much confidence in community reaction. Eastern communities are cohesive units in certain aspects pertaining to well-established cultural mores, but they are not apt to produce a joint-action response to an innovation. They do not "write to their congressmen" to demand action for their community.

Achieving Cooperation

Because of a deep cultural stability, which cannot be moved with bulldozer and steam shovel techniques, Eastern communities are resilient in absorbing external shock. A sense of courtesy prevents an Eastern official from

explaining in advance that a particular project is in opposition to the established cultural pattern. The Western technician must anticipate what opposition to expect if he is to see his project not defeated, but he rarely will be warned. New methods are not resented—quite the contrary—but their adoption depends on the method of introduction. There is always a right way and a wrong way to introduce them depending on the cultural climate of the area concerned.

In the East, every situation must be explored completely; if not, an elaborate program may collapse because no one had discovered that the ferry boat—"it was shown on the map"—no longer exists. Printing facilities, communications, transportation, housing, electricity, and interpreters and stenographers are all on an "if available" basis. The East receives its supplies from many sources; so, the ribbon may not fit the typewriter, nor the electric bulb the socket, nor the needle the syringe. These irritations may be minor or they may be of sufficient magnitude to compromise an entire project.

In a nation the size of Indonesia, one must beware of being too well satisfied with progress in any single instance, particularly if it represents an insignificant fraction of the whole. The philosophy of "any good is good however small" is all very well, but the quart of water should be used to prime the pump rather than given to the passer-by. Technical assistance meant to have catalytic effect should reach the people through agencies which can be expected to continue the work permanently. The development of a single isolated project is useful in the national sense only when it is designed to serve as a demonstration center for teaching purposes. The demonstration center development in Indonesia has been a happy compromise between the danger of losing effect by dissipation of effort on the one hand or losing effect by single-area concentration on the other, but here again the demonstration center had to be associated with a permanent and dependable agency.

The Eastern official participating in cooperative development programs tends to assume that he can bridge the gap between Eastern and Western technology by acquiring the latest, the

largest, and the most complicated apparatus without thought for its maintenance, operation, or utility. This is a well-known tendency and certainly is not exclusively Eastern. It is exemplified by expensive X-ray units combined with inadequate darkroom procedures, or by huge tractors for small fields. Avoiding such errors as these is often the first, and sometimes the most important, element in a technical assistant's contribution.

Difference in Attitudes

An eagerness to institute research may present a formidable problem. The Eastern mind is particularly adapted to investigation, and its achievements are too well known to need comment. However, because of the progress of research in the West during the war years, a grant in the East today may lead to unnecessary duplication or to the exploration of remote aspects of the problem before the application of basic knowledge. Research must not be discouraged, yet the assisting agency must assure itself that established principles are followed in the programs for which it is responsible. The severing of scientific liaison between the East and the West during the war has produced a confusion which will require many years of positive action to correct before research in the two areas will complement rather than overlap.

The Eastern physician tends to focus his efforts on therapeutic medicine rather than on preventive medicine because of the much greater personal reward in the former branch of medicine. This is true the world over, but the contrast in the East is greater, where the choice may be between wealth and fame and poverty and anonymity. The Western technician can assist in correcting this discrepancy; indeed, it is one of his basic objectives. The task, however, is profoundly difficult until community responsibility for the preservation of health has been acknowledged. Until that comes about, the demand will be for therapy, and the response will be in accordance with the demand. The most constructive step to take in the meantime is for organized teams to demonstrate the value of preventive medicine to the community.

The Eastern mind is not as conscious of the importance of problem-solving as is the Western mind. In the East, to acknowledge the

existence of a problem is often considered adequate. There, if a community is told that something "will be done as soon as possible," the "when?" will not be asked. This Eastern reaction, of course, stems from a long experience with deprivation, but it is also a reflection of the difference between East and West in concept of time. This attitude is not a matter of indifference nor of procrastination: it is something quite apart and is difficult for the foreign mind to comprehend. Six months hence and twelve months hence represent not different times, but simply—"the future." This attitude toward time produces an exasperating conflict with Western scheduled methods, but there is a certain realistic wisdom in it which gradually induces the Westerner, perhaps not to adopt the same attitude but to recognize it as locally meaningful, at least until the "something must be done about it" philosophy is accepted in the East.

Finally, either Westerner or Easterner may assume that all difficulties in an ex-colonial nation stem from mismanagement by the former colonial power. This may well be true in specific instances but to adopt any broad generalization is a dangerous obstacle to clear thinking. One must first look critically at the status of those nations or areas of nations which have never experienced colonialism. The adoption of the scapegoat philosophy to explain shortcomings is certainly no help as a basis for discussion and will soon develop a false sense of optimism as to the likelihood of success. The common phrase "nothing has been done for these people" is easy to repeat off-hand, but it is not always supported by a study of the facts. A careful investigation of facts will often show a long history of desperately frustrated effort on the part of the local people against insurmountable odds or against factors which, it must be remembered, were insurmountable until the advent of such effective agents as DDT and the antibiotics.

Java and Demography

The foregoing has depicted certain problems which challenge the planning capabilities of public health authorities in Indonesia. It must be acknowledged that these problems are com-

plicated by certain logistic factors of a magnitude rarely encountered. In some respects they are specifically Indonesian problems because of the extraordinary geography of this nation of islands. The public health planner, however, when considering such obstacles, is confronted by an ominous population situation which overwhelms all other aspects. As a demographic dilemma, the Island of Java is one of the world's most crucial spots. To appreciate this, an academic background is unnecessary: living in Java is enough to instill a sense of dangerous human saturation.

Estimated at 10 million a hundred years ago, the population of Java and nearby Madura is now 52 million and is now increasing by more than 5 million persons a decade. Although the gravity of the situation had been long recognized by the Dutch, the 1930 census figures of 41 million, the population of France at that time, first focused world attention on Java as an island of incredible population density. In 1930, the birth rate of Java and Madura was reported as 27.9 per 1,000 people and the death rate as 19.9. The present rate of increase is thought to be at least 1.5 percent a year, which, unless there are intervening deterrents, would bring the population of Java and Madura to over 100 million before the end of the century. Whether the less severe population deterrents observed in similar situations will obtain in Java, or whether the most paradoxical famine the world has yet experienced will develop in this garden island remains to be seen.

Supply of Rice

Population increase has more than kept pace with increased productivity of rice by irrigation, fertilization, and improved seed, but in Java a finite remedial limit to this productivity is not far away. The per capita daily cost of rice—rice is the hinge of Java's economy—has risen to a figure which is approaching the basic daily wage while rice imports are exceeding a half million metric tons a year.

Some relief may be afforded by a change in food habits, but perhaps the most hopeful project, or at least one that may postpone the crisis longer than any other, is mechanized rice production. This project proposes the development in Borneo, in Sumatra, and in Celebes of

mechanized production areas, operated largely to supply rice to Java's millions.

The story of two disasters reveals the precarious position of the Javanese economy more dramatically than economic theories. The first disaster was the depression of 1929, which struck a sudden and fearful blow at the economy of Java. The second was the Japanese occupation of the island, which brought to light the dangerous imbalance between rice and population. World War II cut off vital imports at the same time that the Japanese army was withdrawing rice from Java to feed its troops in New Guinea. The result was widespread starvation in Java and an estimated 2 million deaths.

No Ready Solution

Reduction of population growth by control measures would require a mutation in cultural mores over a period of time too long to solve the problem of imbalance. Permissible polygamy, the prestige value of early marriage and large families, and the status of women in general are all contributing cultural factors. In the absence of any other form of insurance, the value of many children and grandchildren in an agricultural family is an age-old incentive for uncontrolled reproduction.

Since all Indonesia except Java and Madura is relatively sparsely settled, the concept of transmigration is appealing. Transmigration was begun many years ago by the Dutch. Because it is a sound project for economic development, it will probably continue, but it can have little effect on the population of an island that is increasing by more than a half million persons a year.

While we are promulgating public health programs in the presence of such a formidable dilemma, we hear protest against measures which will decrease infant mortality and only add to the magnitude of the impending disaster. There always has been headshaking over the wisdom of saving lives in famine areas, but in recent years the headshaking has given way to concise and sometimes cynical expressions of disapproval. Public health measures are attacked for doing no more than preserving lives for ultimate starvation. Since we face the choice between disease and famine, so the critics

say, let us preserve disease to eliminate a fraction of the population so that we can avoid famine for the whole. This is indeed a strange bedfellow to be espoused in the cause of human welfare.

To preserve disease is to allow unnecessary death and incapacity for work. How much of a gap is there between allowing death and arranging it? The proposal is dangerously close to genocide and is unacceptable even if it were not known that birth rates rise with disease, ignorance, and poverty and eventually decline with better health, education, and economic status. The fact that the reaction is eventual, and not immediate, can have no bearing on the wisdom of the objective selected, for no solution is immediate.

No program devoted to human welfare can afford to treat disease, poverty, and ignorance as if they were separate entities striking a community merely by coincidence. We know too well that they are part of one another, inseparable in both cause and solution. One can scarcely imagine a malaria-stricken farming population staggering off to increase the rice yield, of yaws-infected school children winning their way to better things, all patiently anticipating the day when someone decides that it is safe to institute disease control. The illiterate villagers are apt to know, by virtue of having lived with their problem since time began, that they cannot meet the demands of education and improved economy without the hope of being healthy.

Epizootiology of Anthrax

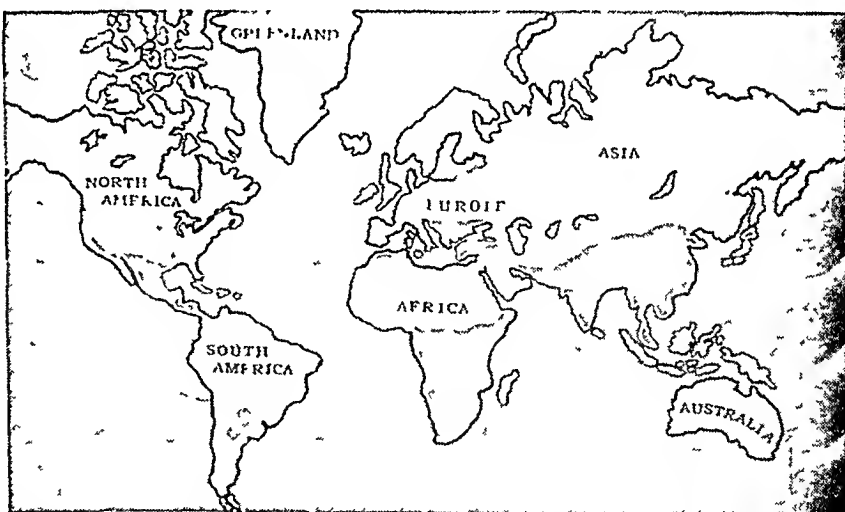

35 mm., sound, color, 9 minutes, 1952.

Audience: Veterinarians, practicing physicians, instructors and students in veterinary and medical schools, and public health personnel interested in anthrax.

Available: Loan—Communicable Disease Center, 50 Seventh Street, N. E., Atlanta, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

This film is designed as an aid in diagnosing and controlling anthrax, for centuries a killer of man and his domestic animals. Although modern antibiotics have contributed toward its control, it is still a serious problem to stockmen, veterinarians, and public health workers.

In depicting the epizootiology of anthrax, the film shows the cycle of infection and appearance of the spores of the etiological agent, *Bacillus anthracis*.

Anthrax occurs throughout the world. (Endemic areas indicated by shaded areas.)

lus anthracis. The case history of the spread, diagnosis, and final control of an epizootic of anthrax arising from an imported shipment of bonemeal which was contaminated with the spores of *B. anthracis* is included. Attention is called to the worldwide distribution of anthrax endemic areas, the susceptibility of

animals to the disease, the usual modes of infection, and the application of control measures.

The control of anthrax, the film points out, depends on early diagnosis followed by thorough sanitary measures and the constant vigilance and cooperation of stockmen, veterinarians, and public health officials.

Histoplasmin Sensitivity In Mississippi— A New Boundary

By ROBERT M. O'NEAL, M.D.

In northern Mississippi, infection with histoplasmosis is about three times as common as in the southern half of the State. This is especially true of the delta section in the northwest.

Results of a study to evaluate the significance of skin tests for systemic mycoses suggest that the northern part of Mississippi lies within the area of endemic histoplasmosis in the United States. The study more clearly defines the southern border of this area, which is usually described as the middle west or the Mississippi River Basin and as extending south through Tennessee. Mississippi to the south thus compares as a border State with Kansas to the west of the area of high prevalence, although the demarcation is more definite in Kansas. Christie (1) considered Mississippi a part of the endemic area when he reported high infection rates of over 55 percent whereas Palmer (2) considered the State to be south of the area of high prevalence.

Skin Test Reactions

In the present study, skin tests with histoplasmin, blastomycin, and coccidioidin were performed on 295 patients of the Mississippi State Sanatorium, the only tuberculosis sanatorium in Mississippi, during the period March 1951 to March 1952. Sixty-five of the group (22 percent) reacted positively to histoplasmin (see table).

In northern Mississippi, 31.5 percent of the patients tested were positive reactors to histoplasmin. In southern Mississippi, 12.8 percent

were positive. Only 0.7 percent (2 patients) reacted positively to blastomycin, and 0.7 percent reacted positively to coccidioidin.

Neither of the two positive reactors to blastomycin reacted to histoplasmin, but both reactors to coccidioidin had positive reactions to histoplasmin identical in size to the coccidioidin reactions. Both also gave a definite history of infection typical of coccidioidomycosis during residence in the San Joaquin Valley in California. The following statistical data, therefore, refer only to the histoplasmin test.

Geographic Variation

When all tests were plotted as to county of residence (see map), it was apparent that there was a significant geographic variation. County of residence was considered the one where patients had lived for 1 year prior to admission to the sanatorium.

For the purposes of the study, the State was divided into northern and southern Mississippi along an imaginary line at the Big Black River which flows east-west centrally into the Mississippi River. Below the Big Black River are the coastal plains. Above the river are the delta section of the northwest and the hills of northeastern Mississippi.

Of the 149 patients residing below the dividing line of the river, 19 (12.8 percent) were positive to histoplasmin. Above the river, 46 (31.5 percent) of the 146 persons tested were positive. This difference is statistically significant.

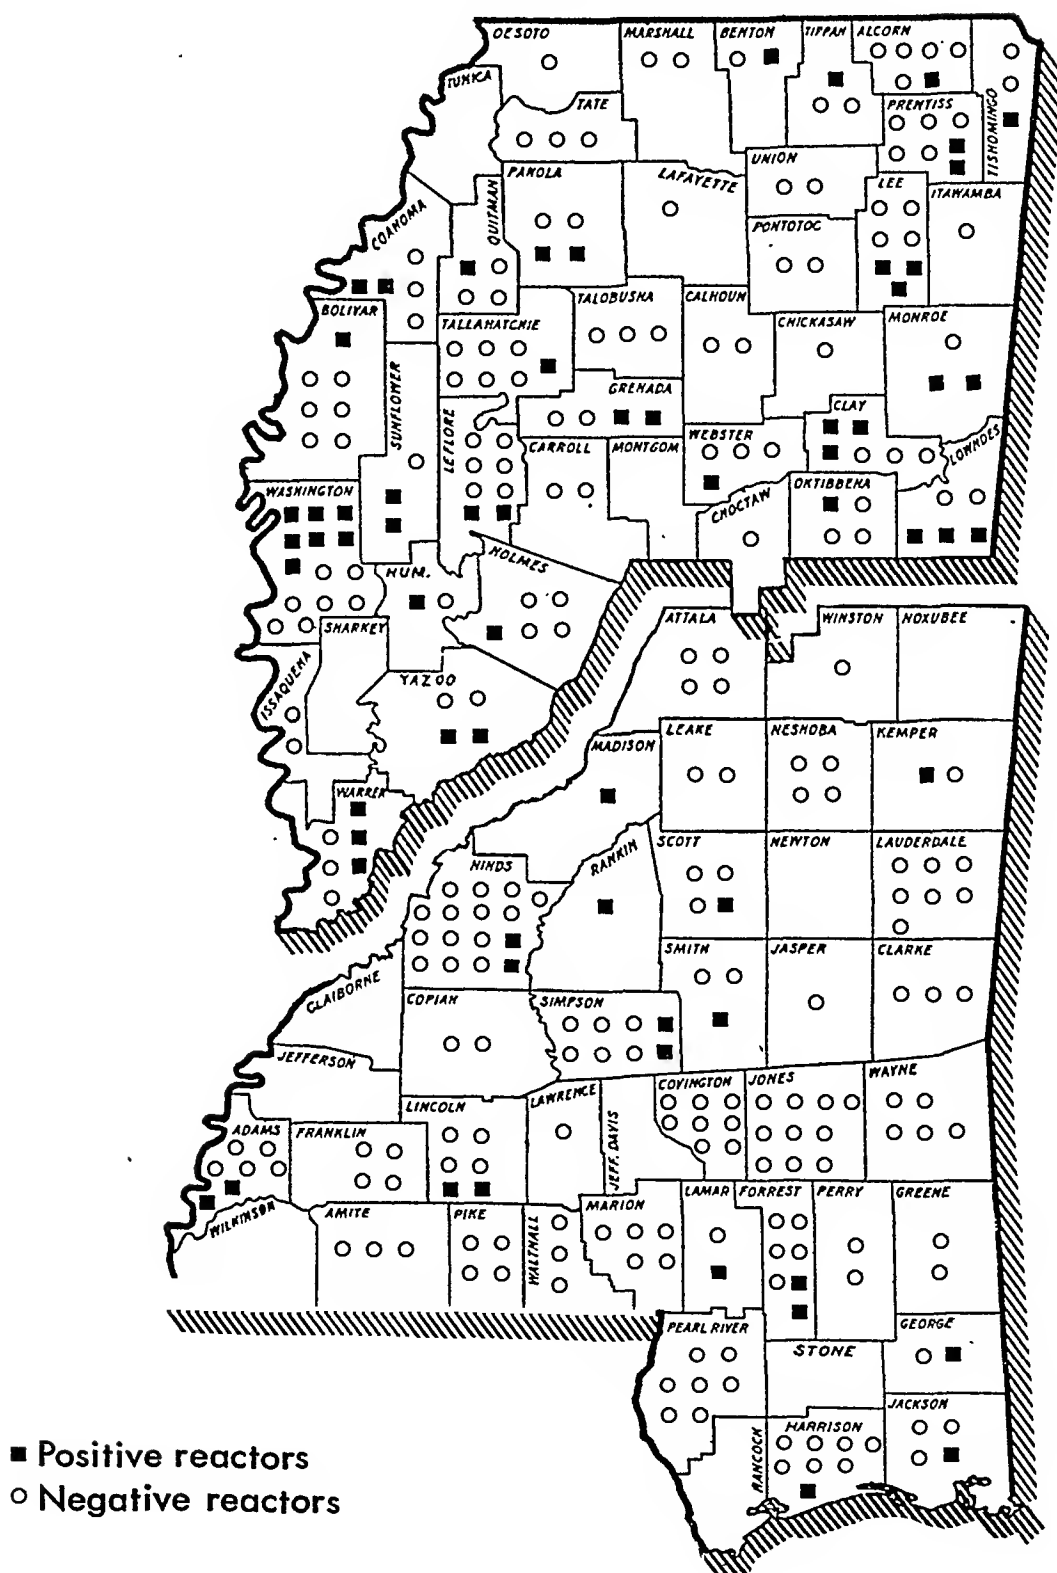

When the 13 counties in the delta section of northwestern Mississippi, the area of greatest prevalence, were considered apart from northern Mississippi, 61 tests were plotted for the area. Twenty-two (36.0 percent) were positive to histoplasmin. Our proven case of histoplasmosis (unreported) was from Bolivar County in the delta. It was not included in the skin tests because it was a diagnostic problem.

Materials and Methods

Blastomycin, coccidioidin, and histoplasmin concentrates were prepared each month in a sterile dilution of 1:1000 which was kept under refrigeration. New syringes were used and labeled for the respective antigens. One-tenth

Dr. O'Neal, now an American Cancer Society clinical fellow in pathology at the Massachusetts General Hospital, Boston, was with the medical service of the Mississippi State Sanatorium, Sanatorium, Miss., in 1949-52.

Geographic distribution of histoplasmin skin tests in northern and southern Mississippi

Results of histoplasmin skin tests in Mississippi

Item	Total	Sex		Race		Geographic division	
		Male	Female	White	Negro	Northern Mississippi	Southern Mississippi
Number of tests.....	295.0	127.0	168.0	207.0	88.0	146.0	149.0
Percentage of reactors.....	22.0	28.3	17.3	19.8	25.0	31.5	12.8
Standard deviation.....	2.41	4.00	2.92	2.77	4.62	3.84	2.74
Difference.....		11.0		5.2		18.7	

cubic centimeter of antigen was injected intradermally into the skin of the left forearm (histoplasmin), right forearm (blastomycin), and right upper arm (coccidioidin) simultaneously as suggested by Smith (3). Tests were read at 48 hours, and induration of 5 mm. or more was considered positive. Doubtful tests—there were only two—were considered negative.

The subjects were routine sanatorium admissions between 12 and 63 years, with an average age of 35.1 years. The age distribution in the northern and southern sections was not determined, and it is believed there could be little variance between the two samples. Age, however, was not considered in evaluating results because the percentage of histoplasmin sensitivity is highest in the young adult and middle age groups composing most sanatorium admissions (4, 5).

Critically ill patients were avoided because "critical illness exerts a depressing effect on skin sensitivity to tuberculin and histoplasmin" (6). Tests performed as diagnostic studies were excluded in an attempt to avoid sampling error.

Other Findings

Sex. Of the 127 men tested, 36 (28.3 percent) were positive to histoplasmin (see table). Of the 168 women, 29 (17.3 percent) were positive. This agrees with other studies which have determined that the rate of infection is slightly lower in women (5). The differences in this study are not statistically significant.

Race. Of the 207 white patients, 43 (19.8 percent) were positive. Of 88 Negro patients, 22 (25 percent) were positive. This differs from other studies in which the whites seemed to be more sensitive than the Negroes (5, 7), but the difference in rates is not statistically significant.

Statistical Significance

On the basis of the histoplasmin tests, the difference between the prevalence of reactors in northern Mississippi and those in the southern area is more than 2.5 times the standard deviation of the difference. Using this same level of significance, no significant difference between the Negro and white patients was demonstrated, and the difference between the sexes was of questionable significance.

NOTE: Blastomycin concentrate (B-8564) and histoplasmin concentrate (CT-189) were furnished by Eli Lilly & Co., Indianapolis. The coccidioidin (special dilution 1:10, lot 49028) was obtained from Cutter Laboratories, Berkeley, Calif.

ACKNOWLEDGMENT

Miss Margaret E. Rice, supervisor of public health statistics, Mississippi State Board of Health, assisted in analyzing the findings.

Recipients of the Master's Degree In Sanitary Engineering

By WALTER A. LYON, M.S.S.E., and ARTHUR P. MILLER, C.E.

TO PERMIT a quantitative assessment of the present and future supply of trained sanitary engineers, it is necessary to determine the number of graduates who follow the profession. In an earlier report (1), such data were provided concerning graduates from undergraduate curricula and options in sanitary engineering. The present study is designed to provide similar information about those who have completed graduate work in sanitary engineering at the master's level.

In order to throw additional light on the place of graduate work in sanitary engineering education, certain other statistical data are also discussed. These relate to the undergraduate background, the amount of experience prior to entering graduate school, and the employment distribution of the graduates. Particular attention is given to characteristics that the graduates from individual schools have in common with respect to prior experience and choice of employment.

Method and Data Used

Miller (2) showed that 44 universities and colleges in the United States at some time dur-

ing the period 1899-1951 granted the master's degree to individuals majoring in sanitary engineering. From these, a group of 28 institutions was drawn. These schools granted the master's degree in sanitary engineering to 1,023 nationals of the United States during the period 1900-1951. This number of graduates, constituting 86 percent of all United States nationals receiving a master's degree in sanitary engineering during those 52 years (1900-1951), was used as the basic material for this study.

The universities and colleges in the group were divided into two subgroups: one consisting of those schools which, in our study, were represented by 30 or more respondents who were United States nationals and the other by those which had fewer than 30. In this way, 7 "heavy producers" (Harvard University, Johns Hopkins University, Massachusetts Institute of Technology, University of Michigan, New York University, University of North Carolina, and University of Wisconsin) and 21 "light producers" were selected in order that data might be provided for both classes of institutions. Although the number of heavy producers was somewhat disproportionate, the number of light producers which are included assures their representation. Wherever there were statistically significant differences between the characteristics of schools or between "heavy and light producers," these will be indicated as significant.

In the analysis of the data, tests for significance were used where the need for such a test arose. Wherever, in this report, a difference is indicated as being "significant," this means that the difference was significant at a level of $P=.05$. The test employed was that described by Zubin (4) which by the use of nomographs determines the significance of the differences between

Mr. Lyon, formerly with the Division of Engineering Resources, Bureau of State Services, is now with the Division of International Health, Bureau of State Services, Public Health Service, and assigned to Bangkok as consultant in sanitation problems in Thailand. Mr. Miller is chief of the planning and development branch, Division of Engineering Resources.

the relative frequencies of events in two contrasted series or groups.

The colleges and universities included in the study provided lists of their graduates and the best available mailing address for each one. An explanatory letter with a reply post card was sent to each person and followup action was taken as long as it appeared to be productive of results. The information given by each respondent was edited, coded, and entered on punch cards for mechanical tabulation. Usable

data were obtained from 874 individuals or 85.4 percent of the group (1,023) to whom cards were mailed. Those who had also earned doctorate degrees in sanitary engineering were excluded.

Table 1 shows a summary of the total number of master's degrees in sanitary engineering granted by the 28 schools in the sample, the number of respondents from each institution, and other information concerning the composition of the sample.

¹ See reference 2.

² Excluded because of no or insufficient information. In this group, there are 30 who also obtained a doctorate degree.

Schools and Their Graduates

The number of schools granting the master's degree in sanitary engineering has kept pace with the rapid increase in the number of such degrees awarded. Ten colleges were awarding the master's degree to individuals majoring in sanitary engineering by 1925; by 1935 the number had risen to 22, by 1945 to 32, and by 1951 to 44 with an additional 13 schools prepared to do so if candidates presented themselves.

The student load carried by the schools is not equally distributed. For example, of all the degrees granted during the last decade (1942-51), almost two-thirds were awarded by one-eighth of the schools active during that period.

Loss From the Profession

For the purpose of this study, a graduate was considered to have remained in the profession if, during the year 1951, he was in an occupation in which he devoted all or part of his time to the application of engineering knowledge in the control of the environment in order to promote and protect the public health in administrative, promotional, operational, teaching, testing, design, or research activities.

In the bachelor's level study (1), all those who spent 50 percent or more of their time in sanitary engineering work were classified as being in the profession. In this study, all those who were practicing sanitary engineering any portion of their time were so classified. This change in definition accounts for 8 of the 35.8 percent difference between the "percents remaining in the profession" when the bachelor's and the master's groups are compared.

As stated before, the total number of students from the schools in the sample from whom usable information was received was 874; of these, 763 or 87.3 percent remained in the profession in 1951.

If we compare the percents remaining in the three educational levels, we find the following distribution:

*Percent of graduates
remaining*

<i>Degree level of graduates</i>	<i>in the profession</i>
Bachelor's-----	51.5
Master's-----	87.3
Doctorate-----	97.3

The figures above are based on degrees granted rather than on individuals. The same person may have been included twice or even three times. (The number of doctorate degrees earned in sanitary engineering to date is relatively small; therefore, data on them are used in this study only in this one comparison.) Most of those who received doctorates had also received the master's degree in sanitary engineering. This is not true, however, for those who earned degrees only to the master's level. Only about one-third of these had studied sanitary engineering at the undergraduate level.

The difference in percents remaining between the bachelor's and the master's degree levels even after taking into consideration the 8 percent accounted for through change in definition previously mentioned is about three times as great as the difference between the master's and the doctorate levels. The difference in percents remaining between the bachelor's and the master's levels is probably due in part to the fact that most of the master's degrees were granted more recently than most of the bachelor's degrees. The median master's degree in the sample used in this study (1900-1951) was granted in 1947. The median bachelor's degree in the undergraduate study (1) (1910-49) was granted in 1937. This means that the median bachelor's level graduate has had more time (that is, more of a chance) to leave the profession than has the median master's degree recipient.

In comparing the percents of graduates from each school who have remained in the profession, only the graduates during the 1942-51 period were considered, because a number of the schools in the study did not begin to grant the master's degree in sanitary engineering until some time during that period.

As shown in table 6, there were relatively small differences in the percents remaining among those from each school. In some cases, the number of graduates involved was too small to permit drawing significant conclusions.

When the heavy producers during the 1942-51 period were compared with the light producers, a significant difference in the percents remaining was found. (Since, for the 1942-51 period, the line of division between heavy and light producers was drawn at 15 respond-

ents, the University of California is included for this period only among the heavy producers.) For the heavy producers, the percent remaining was 93.5, whereas for the light producers it was 84.7. The reasons for this difference will become more obvious in the discussions of pregraduate-school experience and type of employment which follow.

Undergraduate Background

The undergraduate background of about half of the master's degree recipients in sanitary engineering was the civil engineering curriculum; somewhat more than a third completed the sanitary engineering option of civil engineering or the sanitary engineering curriculum; and about one-sixth completed some other type of engineering curriculum. Table 2 shows this, the percents remaining, and the percents which had pregraduate-school experience for each type of undergraduate work.

Table 2 also shows that increasing percents of the master's degree recipients who had undergraduate work in civil engineering, the sanitary engineering option of civil engineering, sanitary or public health engineering, and other types of engineering curricula, remained in the profession. The percents who have had 1 year

or more of pregraduate-school experience vary in the same order. The differences in these percents are small, but they follow a pattern which suggests the general rule that the more a man is exposed to sanitary engineering either via experience or education, the more likely he is to remain in the profession.

Experience Prior to Graduate Work

Many of those who earned the master's degree in sanitary engineering had gained some experience in the field before beginning graduate work. In this study, we have assumed that only those who have had 1 year or more of such pregraduate-school sanitary engineering experience have had a significant amount of such experience. Table 3 indicates that more than half of the master's degree recipients fall into that category.

About 57 percent of those who remained in the profession after having completed graduate school work, had a year or more of pregraduate-school experience whereas only 24 percent of those who left the field had such experience. This is, of course, to be expected since an engineer who had some pregraduate-school experience has had more chance to decide whether or not he likes sanitary engineering than one who has not. Actually, of the 874 graduates in the sample, only 27 or 3 percent who had had pregraduate-school experience, left the profession at some time subsequent to the completion of graduate work.

When the graduates are grouped by the type of their 1951 employment, there are considerable differences in the proportions who had pregraduate-school experience. Table 4 demonstrates this.

The second column of this table shows the percents of all sanitary engineers in each type of employment who have reached the master's level of education. This could be considered as an indication of the extent of utilization of master's level men in each employment category. The fourth column shows the percents of graduates in each employment category who have had a year or more of pregraduate-school experience. This may be considered an index of the opportunity given by the employer, or taken by the student, to return to school for graduate work.

Table 2. Distribution of type of undergraduate curriculum completed by percent remaining in the profession in 1951 and pregraduate-school experience in sanitary engineering

¹ Because of rounding, details may not add to totals in this and all subsequent tables.

Since the majority earned their degrees rather recently, it is assumed that most of the graduates have remained in the same employment category in which they were prior to their graduate studies.

As a general rule, in those employment categories where the greatest use of master's level men has been made, a greater proportion of the

men have returned to school to earn such a degree. However, there seem to be two exceptions to this rule. In the case of public works agencies where only a small proportion of sanitary engineers hold a master's degree, a high proportion have obtained them by returning to school after working in the field. With academic institutions, the opposite appears to be

Table 4. Relationship between type of employment and pregraduate-school experience in sanitary engineering

the case. Although a high proportion of educators and researchers hold the master's degree, relatively fewer of them gained experience before earning their degree. In some of the employment categories, the numbers involved were too small to produce significant information.

Sanitary engineers who return to school to earn their master's degree after having gained some experience seem to favor certain schools. The data show that significantly greater percentages of graduates from Harvard University and the University of Michigan have had more than 1 year of pregraduate-school experience. This also appeared to be the case (although not statistically significant) for the Johns Hopkins University, New York University, and the University of North Carolina. Conversely, a significantly smaller percent of the graduates from the University of Wisconsin and the Massachusetts Institute of Technology have had such experience. When the heavy producers are compared to the light producers, 57 percent of the graduates from the former are found to have had more than 1 year of pregraduate-school experience as compared to 30 percent of the graduates from the latter. This difference is significant.

Time Spent in Sanitary Engineering

Because of the nature of sanitary engineering and particularly because of its relation to other types of public works, there are a number of graduates who spend only a portion of their time in sanitary engineering. This is particularly true for sanitary engineers who have reached a higher level of responsibility, such as the head of a large consulting firm, a city engineer, or the dean of a school of engineering. Table 5 shows this distribution, and compares it with that of the entire profession.

Four-fifths of the master's degree recipients in the sanitary engineering profession devoted most of their time to sanitary engineering work. When compared with the entire profession, the recipients of master's degrees in sanitary engineering devote considerably more of their time to work in sanitary engineering than do non-recipients. This is probably so in part because the master's group is younger and because a greater proportion of this group is in public

Table 5. Distribution of all sanitary engineers and of recipients of the master's degree by percent of time spent in sanitary engineering work

health work as compared with the profession as a whole.

When we study the graduates from chronologically selected groups of classes, we find noteworthy differences in the percents remaining in, and in the distribution of percent of time spent on, sanitary engineering work.

Figure 1 shows that the greater the time elapsed since graduation, the larger becomes the proportion of those who have left the profession. The high percentage of graduates from the 1912-21 classes who have left the profession is no doubt due in part to retirement. The progressive increase in the size of group I among the more recent graduates is probably due to the fact that younger men tend to work in more specialized areas and in part due to the recent expansion of environmental health activities in water pollution control and other fields.

How much of this change is due to program growth and how much of it can be attributed to the natural broadening of individual responsibility that comes with advancing professional experience can only be determined by periodic studies of this kind which will compare future observations with present findings.

Employment Distribution

The types of employment favored by graduates of different colleges and universities appear to differ. To determine the extent of these differences, the graduates who have remained in

Figure 1. Percentage distribution of recipients of a master's degree for selected 10-year periods, by time devoted to sanitary engineering work in 1951.

the profession from each heavy producer school were compared in each case with the graduates from all the remaining schools combined by the type of employment in which they were found in 1951. It was possible to make these comparisons only for the heavy producers, as only they

had graduates in sufficient numbers to justify significant conclusions.

Table 6 gives the employment information as of 1951 for the graduates of each of the 28 schools in the sample who were then in the profession.

See footnotes at end of table.

Harvard University, when compared to all other schools combined, has a significantly greater proportion of its graduates working for public health agencies and a significantly smaller proportion employed in public works agencies. Harvard also appears to have a smaller proportion of its graduates who have reached only the master's level serving as university teachers, although more than half of the Harvard doctorate recipients are now working in academic institutions.

Graduates from the University of Michigan also seem to choose, in smaller proportions

than do graduates from the other schools combined, employment with consulting firms, industrial concerns, and academic institutions.

The picture among the graduates from New York University is somewhat reversed from that of the University of Michigan. Significantly smaller proportions are in public health and academic work, while significantly greater proportions are in public works agencies, consulting firms, and industrial concerns.

When the Massachusetts Institute of Technology was compared with all the other schools, it was found that a significantly small percent

¹ Includes professional associations, nongovernmental agencies, and military service.

² No master's degree in sanitary engineering granted in the 1942-51 period.

of its graduates are in public health agencies and a significantly greater percent with consulting firms. MIT graduates also appear to favor employment in academic institutions.

The employment distribution of the graduates from the University of North Carolina appears to fall closer to the average than that of the other heavy producers. There were no significant differences in the employment distribution of its graduates when they were compared with those of the other schools.

Graduates from the Johns Hopkins University showed an employment distribution fairly

close to the average except that they favor public works agencies somewhat and are represented in a significantly smaller proportion in consulting firms.

The University of Wisconsin is the only school which has a significantly higher proportion of its graduates employed in academic institutions.

When heavy and light producers were compared, a few differences were found in the employment distribution of the graduates from the two groups of schools. The heavy producers had a significantly higher proportion of their

graduates employed in public health agencies and the light producers had almost three times as great a proportion of their graduates employed in academic institutions as did the heavy producers. As a matter of fact, more than half of those employed in the academic field came from the light producers and, interestingly enough, the University of Wisconsin, which produced the least number of graduates among the heavy producers, also had a high percentage of its graduates teaching.

If these data are pursued further, it becomes evident that only a small proportion (15.3 percent) of the master's degree recipients from the heavy producers who are now in the academic field, are teaching at the same institution that awarded them their master's degrees. But of more importance, these data also reveal that the light producers not only turn out a disproportionate share of teachers, but that the majority of these teachers (64.3 percent) have remained with the same institution from which they earned graduate degrees. It is likely that the Engineer's Council for Professional Development (see its 19th annual report, 1951) had this in mind when it wrote: "As schools grow, the pressure for staff expansion led to recruiting by the simple process of keeping on recent graduates, and then allowing them to do their graduate work, if any, while teaching. In this way, there was a subtle influence of continuity of curriculum with little urge for reevaluation or vitality of concept of objectives."

Growing Importance of the Master's Degree

While there has been a considerable increase in the number of sanitary engineering degrees granted on all levels, the number of master's degrees has increased at a greater rate than the number of bachelor's degrees.

The total number of master's and bachelor's degrees granted to students majoring in sanitary engineering in the United States each year during the period 1900-1951 are shown in figure 2. The points on this figure have been plotted on a logarithmic vertical scale in order to facilitate the comparison of relative differences. Between the years 1917 and 1941, the data appear to assume a certain degree of linearity (see note on page 727).

Figure 2. Total number of bachelor's degrees and of master's degrees granted upon completion of study in sanitary engineering in the United States each year, 1900-1951.

The figure shows that the average rate of increase in the annual number of master's degrees granted has been considerably greater than that of the bachelor's degrees. The two curves intersect during 1951. This is, of course, not true for the entire engineering field.

Although there is no evidence that sanitary engineering education on the undergraduate level is on the decline, there is a definite shift of emphasis toward graduate level education in this field. Educational opportunities for veterans have undoubtedly been partly responsible for this shift.

Future trends in a field as small as this are difficult to predict. Recent estimates (1) of the expected number of graduates from the bachelor's level appear now to have been somewhat low. This is because the estimates of future production of all engineering graduates were recently raised, presumably because of the effect of the recent publicity on the shortage of engineering manpower. It looks now as though we might expect between 500 and 600 sanitary engineering graduates at the bachelor's level

NOTE: When a straight line is fitted to the points by the method of least squares for the period 1917-51 (see fig. 2 and p. 726 of text), the mathematical expressions for the best fitting lines became:

$$\text{Log } Y_{cb} = 1.77780 + .02777x \text{ for the bachelor's degrees and}$$

$$\text{Log } Y_{cm} = 1.28388 + .05654x \text{ for the master's degrees.}$$

x equals the year minus 1934 during which Y_c degrees were granted. The year 1934 was chosen as the origin for the x-axis.

during the 4-year period, 1953-56. Figure 2 indicates that if the 34-year (1918-51) trend continues, the annual number of master's degrees granted may be expected to exceed the number of bachelor's degrees.

The availability of public, philanthropic, and other funds for graduate education, as well as selective service policies and general economic trends, are each likely to have an impact upon the number of men who will be able to earn master's degrees in sanitary engineering in the years to come. No matter what outside forces might introduce unexpected change, the record of the past 34 years clearly shows the profession's increasing preference for graduate training in the structure of sanitary engineering education.

Summary

A quantitative study has been made of those who received master's degrees in sanitary engineering during the 52-year period 1900-1951. Twenty-eight colleges and universities, whose graduates represent 86 percent of all the United States nationals who received master's degrees in sanitary engineering during that period, were included in the study. Upon inquiry, 85.4 percent of these graduates responded with usable data.

It was found that 87.3 percent of the master's degree recipients were in the profession in 1951.

The median master's degree recipient gained 1.35 years of sanitary engineering experience after receiving his bachelor's degree and before beginning his graduate studies. Of the entire group, only 3 percent who had had pregraduate-school experience, left the profession at some time subsequent to doing graduate work.

Among the master's degree recipients reporting, 83.6 percent earned their degrees at 7 of the schools (heavy producers) and 16.4 percent, at the other 21 schools (light producers). A significantly greater proportion of graduates from the heavy producers than from the light producers were practicing sanitary engineering in 1951.

The patterns of employment distribution of the graduates from certain individual schools and from the heavy and the light producer groups differ in part significantly from each other. Particularly outstanding is the fact that more than half of those in the academic field have received their degrees from the light producers and almost two-thirds of them are employed at the institution in which they received their master's degree.

Slightly more than one-third of those who received the master's degree in sanitary engineering had a sanitary engineering undergraduate education. About half took the civil engineering curriculum and one-sixth had completed undergraduate work in one of the other branches of engineering.

The relative trends in the production of bachelor's and master's level graduates in sanitary engineering over the past 34 years suggest that the point has been reached at which the annual production of master's level graduates can be expected to exceed that of the bachelor's level graduates. This observation, together with the fact that roughly 8 out of 10 master's degree recipients as compared with 5 out of 10 bachelor's degree recipients, stay in the profession for which they received their schooling suggests that the educational needs of the profession are being more successfully met by graduate-level education.

ACKNOWLEDGMENT

The authors are appreciative of the advice on statistical problems given by Theodore D. Woolsey, biostatistician, Division of Public Health Methods, Public Health Service.

Public Health Service Staff Announcements

Dr. Russell M. Wilder, first director of the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Public Health Service, retired July 1, 1953. Dr. Wilder, internationally known for his work in metabolic diseases and nutrition, came to the Public Health Service in January 1951 shortly after his retirement from the Mayo Foundation where he was professor of medicine and chief of the department of medicine. He will continue as a member of the Board of Editors of *Public Health Reports*. Dr. Wilder will make his home at Rochester, Minn.

Dr. Eddie M. Gordon has been appointed medical officer in charge of the Public Health Service Hospital (National Leprosarium), Carville, La., to succeed Dr. Frederick A. Johansen. Dr. Gordon has been in charge of the Public Health Service Hospital in Chicago. He has also held clinical positions at the Service medical facilities in San Francisco, Boston, Seattle, and

San Pedro, and has been assigned medical officer in the U. S. Consulates at Hong Kong, China, and Manila, P. I.

Dr. Frederick A. Johansen, who retired June 1 after 29 years of service at Carville, participated actively in the evolution of the modern sulfone therapy. Later he guided the installation and organization of the community activities and rehabilitation services at the National Leprosarium. He is widely recognized as an authority on Hansen's disease.

Octavia Heistad, Public Health Service nurse officer, has been assigned to the Point IV technical aid program in Libya where she will work with Libyan nurses and other health aides in extending public health nursing. Miss Heistad, who has done public health nursing in Chicago and Detroit for the past 4 years, will join Bertha Tiber, assigned to Libya as chief nurse under Point IV.

Rapid Method For Distilling Fluorides From Water Samples

By R. E. FRAZIER and H. G. OLDFIELD, M.S.

Distillation of fluorides from water samples, when concentration of the sample is unnecessary, may be made in less than 30 minutes, one-third of the time required for distillation by the standard method, by simply introducing the sample itself at a slow constant rate into a mixture of water and sulfuric acid kept boiling at a temperature of 140°C . Where frequent fluoride distillations are required, the timesaving features of this method make it particularly useful.

The method described here evolved from the logical supposition that with a constant distillation rate and temperature and with fluoride entering the flask in the sample water and leaving the flask in the distillate, the concentration of the fluoride in the distillate would eventually be the same as the concentration in the sample. The rate of distillation might have a slight effect on the point at which equilibrium is attained, but equilibrium must be reached at some point as long as the rate is constant.

Distilling Apparatus

The distilling apparatus used in the experimental work to be described is shown in the accompanying illustration. The flask is a 500-ml. three-necked boiling flask fitted with a thermometer which extends into the liquid being distilled. The sample lead-in tube is a 0.1-ml. pipette connected to a separatory funnel by a length of rubber tubing and fitted into one neck of the flask by means of a rubber sleeve. All other joints are standard taper glass. The separatory funnel has a notched stopcock for

Mr. Frazier is chief and Mr. Oldfield is bacteriologist of the engineering laboratories section, division of environmental sanitation, Minnesota Department of Health.

Distillation apparatus used in experimental work on rapid method for distilling fluorides.

easy control of flow at slow rates; a glass tube fitted in a rubber stopper reaches nearly to the bottom of the funnel to provide a constant head of liquid. The heating unit is a 750-watt heater with transformer control.

Procedure

The flask is charged with 15 ml. of sulfuric acid, glass beads, a small amount of silver sulfate, and sufficient water to give a boiling point of 138° to 140°C .

In making a distillation, the sample is introduced at a rate sufficient to maintain a temperature of 138° to 140°C . with the heating unit set at full capacity. With the apparatus described, distillation proceeds at the rate of approximately 7 ml. per minute. All tests described below are based on a distillation rate of 7 ml. per minute at 138° to 140°C .

At the end of one distillation, the excess sample in the separatory funnel is discarded and a new sample introduced, the lead-in tube to the flask being removed and flushed with the new

sample. The separatory funnel and lead-in tube are again placed in position, and the distillation is restarted. The acid charge in the flask may be used repeatedly. As many as 20 distillations from one batch of acid have been made with no apparent difficulty. The frequency of acid renewal should probably depend upon the mineral and organic-matter content of the water analyzed.

Equilibrium Studies

Preliminary experiments were made with a known concentration of fluoride in distilled water in order to determine how rapidly equilibrium between input and output would be established. One hundred milliliters of distilled water were distilled through the apparatus and discarded. Then a solution containing 2 ppm fluoride was distilled, and five 50-ml. portions were collected. Distillation of the fluoride solution was discontinued and distilled water substituted, five 50-ml. portions again being collected.

The fluoride content of the portions collected and of all subsequent samples described in this report was determined by the Sanchis method, modified by Scott, as outlined in "Standard Methods for the Examination of Water and Sewage," ninth edition. Analysis of these samples gave the results in table 1, which indicate that for routine work distillation of 50 ml. to waste at the beginning of each new sample should be sufficient.

In order to determine whether or not equi-

Table 1. Recovery of fluoride in successive 50-ml. portions

Portion No.	Concentration in feed (ppm)	Concentration in recovered distillate (ppm)
1-----	2	1.5
2-----	2	2
3-----	2	2
4-----	2	2
5-----	2	2
6-----	0	.7
7-----	0	.02

librium would be established at a similar rate with tapwater, fluoride was added to Minneapolis tapwater at the rate of 1.5 ppm. The apparatus was cleared of fluorides by distilling 300 ml. of distilled water through it. Then distillation of the fortified Minneapolis water was started, and four consecutive 50-ml. portions were collected. Results of the analysis of these portions, shown below, again indicate that for routine work a sufficiently adequate equilibrium is established after the distillation of 50 ml. to waste.

Portion No.	Concentration in recovered distillate (ppm)
1-----	1.00
2-----	1.56
3-----	1.58
4-----	1.59

Another series of experiments was made with Minneapolis tapwater to determine whether or not the distillation of 50 ml. to waste before collecting a sample would be sufficient for samples with a higher fluoride concentration. After the apparatus was cleared with distilled water, four successive 50-ml. portions were collected from distillate of Minneapolis tapwater containing 5 ppm added fluoride. Results of the analysis of these portions, shown below, indicate that equilibrium is established at approximately equal rates for samples containing about 1.5 ppm and 5 ppm fluoride.

Portion No.	Concentration in recovered distillate (ppm)
1-----	3.75
2-----	4.80
3-----	5.0
4-----	5.0

Accuracy Tests

Further experiments with tapwater were made to determine the general accuracy of the procedure as it would actually be used. Samples of Minneapolis tapwater containing 1.5 ppm added fluoride were alternated with samples of Minneapolis tapwater containing only the naturally occurring fluorides, 50 ml. of distillate being discarded at the beginning of each change. Both the distilled samples and the undistilled samples were analyzed by the standard method. Results of these tests, shown

in table 2, indicate that the technique is sufficiently accurate for routine work.

Other Substances Added

It has been reported that aluminum may cause irregularity in the recovery of fluorides by distillation. Although waters in Minnesota usually contain less than 0.5 ppm aluminum, it was decided to investigate the effect of added aluminum. Test solutions were made by adding 1.5 ppm of fluoride and 10 ppm of aluminum to Minneapolis tapwater. Two hundred and fifty milliliters of this solution were distilled, the first 50 ml. being discarded and two successive 100-ml. portions collected. Then, 250 ml. of Minneapolis water containing 1.5 ppm of added fluoride were distilled, the first 50 ml. again being discarded and two 100-ml. portions col-

lected. The results of the analysis of these samples are tabulated in table 3. There appears to be little or no effect on fluoride recovery either during the time the aluminum was being added or on samples distilled after 2.5 milligrams of aluminum had accumulated in the flask.

A similar experiment was made to determine the effect of dissolved silica on the distillation. Minneapolis water with 1.5 ppm added fluoride was distilled alternately with Minneapolis water containing 1.5 ppm added fluoride and 20 ppm added silica. The dissolved silica content of the original Minneapolis water was found to be 6 ppm by the molybdate colorimetric determination. Results of this experiment appear in table 4. No significant differences were found in fluoride recovery.

Table 4. Effect of silica on recovery of fluorides from Minneapolis water

Portion No.	Fluoride added (ppm)	Silica added (ppm)	Fluoride in distillate (ppm)
1 ¹ -----	1.5	0	1.56
2-----	1.5	0	1.56
3 ¹ -----	1.5	20	1.54
4-----	1.5	20	1.56
5 ¹ -----	1.5	0	1.56
6 ¹ -----	1.5	20	1.56
7-----	1.5	20	1.56
8 ¹ -----	1.5	0	1.56

¹ 50 ml. of distillate discarded before collecting sample.

Conclusion and Summary

The distillation method outlined, which requires less than 30 minutes, appears to be sufficiently accurate for routine work. Equilibrium studies have shown that at a distillation rate of 7 ml. per minute and a temperature of 138° to 140° C., distillation of 50 ml. to waste at the beginning of each new sample is sufficient. The addition of aluminum and of dissolved silica to the test samples does not appear to affect significantly the recovery of fluoride from the distillate.

OCCUPATIONAL HEALTH

Training of Health Workers In Los Angeles Program

In the June 1953 issue of *Occupational Health*, Jack C. Rogers notes that public health personnel have generally refrained from entering the field of industrial hygiene.

The occupational health services in Los Angeles have been confined to the division of occupational health (which Mr. Rogers directs) in the city health department. To compensate for the manpower shortage within the division and still provide adequate health services throughout the city's sprawling area, other departmental personnel are being brought into the industrial health program. This is being achieved with the cooperation of the other administrative units of the city health department.

As a result of the program, sanitarians and public health nurses are getting training and technical guidance in their jobs from the division of occupational health. Similarly, sanitarians are training industrial hygienists in industrial sanitation. Public health nurses are being trained to act as contacts between industry and the division of occupational health. Both are being alerted to spot and report to the health department the occupational hazards they uncover.

Mr. Rogers points out that by the actual designation of the occupational health division as the one unit of the department which is responsible for all contact with industry, the danger of overlapping or conflict in plant inspections or in instructions is eliminated. The division thereby handles all matters involving industry from those problems normally assigned to the occupational health program to those connected with water supplies, cross connections, industrial wastes, and others.

Michigan Training Program In Industrial Hygiene

The need for the control and prevention of occupational disease was recognized as early as 1875 in Michigan, according to John C. Soet, chief of Michigan's division of industrial health. The entire field of official industrial hygiene is faced with the twofold problem of keeping the small total of ex-

perienced personnel at its present level and of having some satisfactory source of replacement.

Finding that its entrance requirement of a year's experience in industrial health was losing potential candidates for careers in industrial health, the Michigan Department of Health now offers a training program for graduate engineers and other qualified applicants. This program is designed particularly to attract graduates in chemical engineering to the profession of public health engineering.

The training program combines field work with classroom and lecture sessions over a 23-week period. It now includes a special ventilation conference at Michigan State College, special industrial health conferences at the Michigan School of Public Health and will include the radiological health course offered by the Public Health Service. Trainees do not assume any real responsibility for the first 2 years but work under the supervision of experienced men.

"Our statistics show that over the years the vast majority do remain in industrial hygiene," Mr. Soet stated, adding that, on the average, the trainees remained for a long period of time—long enough to repay the cost of training.

Suspension Notice

Publication of *Occupational Health*, a monthly since 1940, has been suspended with its July 1953 issue as the result of reduction in appropriations. However, *Public Health Reports*—which in recent issues has presented papers on air pollution, human relations in industry, occupational and environmental aspects of various diseases, and industrial dentistry—will give increased attention to technical topics in occupational health. Official agencies, professional organizations, and teaching institutions not now receiving *Public Health Reports* should inquire of the Public Health Service as to their eligibility for official or free subscriptions. Other groups—and individuals wishing personal copies—should purchase subscriptions. *Use the subscription blank on the inside back cover of this issue.*

Recent issues of *Occupational Health* are available at 10¢ a copy from the Superintendent of Documents, Government Printing Office, Washington 25, D. C.

Legal Notes

on public health

Constitutionality of Delegation of Legislative Powers To State Boards of Health

The provisions of the Arizona State Sanitary Code which were applicable to agricultural labor camps were declared void, and the provisions of an Arizona statute on which the code is based were held to be an unconstitutional delegation of legislative power by the Supreme Court of Arizona on January 15, 1953—*State of Arizona v. Marana Plantations*, 252 P. (2) 87 (1953).

The Arizona statute authorized the Arizona State Board of Health to "formulate general policies affecting the public health," to "regulate sanitation and sanitary practices in the interests of public health," and to "protect and promote public health and prevent disability and mortality."

The court's decision was based on the ground that the statute permits the Arizona State Board of Health to issue "such sanitary laws as its unrestrained discretion may dictate" without statutory guides or criteria.

Pursuant to the statute the Arizona State Board of Health had adopted regulations governing health aspects, water supply, toilets, bathing facilities, housing, fire protection, and garbage disposal at agricultural labor camps. The board of health had charged the defendant, Marana Plantations, with violating these regulations, and the defendant had challenged the basic authority of the board to issue them.

The scope of the police power of States as

it relates to health has been succinctly stated by the Supreme Court of Appeals of West Virginia in *Hayes v. The Town of Cedar Grove*—126 W. Va. 828, 30 SE 2d 726, 731, 156 ALR 702 (1944):

"So far as we know, the power of the State, under its police power, to provide for the health of its people, has never been questioned, but on the contrary, has been stressed as one of the powers which may be given the broadest application; and it is common knowledge that this power has been increasingly exercised, in keeping with advances made in the sciences of medicine and sanitation, in recent years. In these circumstances, courts are reluctant to place limits on what may be done in the interest of the health of a community, so long as unreasonable methods are not employed, nor the natural and constitutional rights of citizens invaded.

"The police power of the State is vested in the legislative branch of our Government, and may be employed or delegated by it, subject only to the control of the courts, to the extent that they may properly act."

Delegations of authority in broad terms to State boards of health to make regulations having the force of law for the protection of public health and for the prevention of disease have generally been upheld by the courts. (See 25 Am. Jur. 287, note 2; 79 L. Ed. 523.) The stricter rule applied in some States, such as Arizona, requires more specific statutory criteria and should be carefully considered when preparing health legislation intended for enactment by the legislatures.

This note has been prepared by the Public Health Division, Office of the General Counsel, Department of Health, Education, and Welfare.

Educational Materials on Water Pollution Control.

Public Health Service Publication No. 256. 1953. 2-fold leaflet. Division of Water Pollution Control, Public Health Service, Washington 25, D. C.

Exhibits, posters, films, and publications may be obtained through Federal and State water pollution control agencies for use by local organizations and groups to aid in the fight to make America's waters safe and clean. Every community needs to feel its responsibility in making and keeping its own water resources clean for drinking and domestic use, for raising crops and livestock, and for recreation uses.

This leaflet contains illustrations and descriptions of the educational materials available to use in the community's fight for clean water. It tells where to send for the items best suited to a specific program for water pollution control.

Basic Drugs—U. S. Public Health Service Hospitals and Clinics.

Public Health Service Publication No. 246. 1953. 165 pages. 50 cents.

The Division of Hospitals, Bureau of Medical Services, Public Health Service, has prepared a handbook of basic drugs for the division's 18 hospitals and 22 outpatient clinics. The handbook is intended as the beginning rather than the arbitrary end in drug therapy. The primary criterion is therapeutic efficacy—selection of the best, the simplest, the fewest, and the safest medicines currently needed in the prevention, diagnosis, and treatment of illnesses. Preference is given to U. S. Pharmacopoeia, the National Formulary, New and Nonofficial Remedies, and Accepted Dental Remedies items.

Unnecessary duplication is avoided in the handbook. Drugs with secret composition are not considered, and

mixtures are included only when they provide substantial advantage over the individual components.

However, "nonbasic" drugs which prove to have a high rate of acceptance by the individual division stations will eventually be added to the list of "basic" drugs in future revisions. The handbook further recommends the rapid and extensive adoption of meaningful, standard drug terminology and the metric system.

The philosophy, objectives, and application of this manual in a general program of maintaining sound drug therapy were presented in an article, "An Objective Approach to Drug Therapy," published in the January 1953 issue of *Public Health Reports*.

Clean Water in the Arkansas, White, Red, and Lower Mississippi Valleys.

Public Health Service Publication No. 252. 1952. 6 pages; illustrations. 5 cents.

It pays to prevent water pollution. Damage to water resources from the wastes discharged by our growing cities and industries can be controlled. The publication cites experiences of several cities of the southwest-lower Mississippi area which were compelled to find new water supply sources because the rivers flowing through or near the cities became polluted. Questions asked are: What happens if the new sources get polluted? Do we go to still more distant ones? Suppose all our public waters except those too small or remote for use get polluted, what then?

Reference is made to a State-Federal report on water pollution in the Arkansas area which lists more than 500 cities as needing some kind of facility for waste treatment. The total cost of those facilities is estimated at \$50 million, but divided among the cities and financed over a period of years, the cost to each

family in the community will be no more than a few cents a day. This, the booklet states, is little enough to pay in return for abating an evil that endangers health, spoils water for industrial and agricultural use, kills fish and wildlife, ruins recreational areas, and is undermining the very foundation of our highly urbanized and industrialized American way of life.

Let's Have Clean Water.

Kit of materials to aid community leaders in their efforts to solve local water pollution problems. Public Health Service Publication No. 264. 1952. 5 parts. \$1.25 per kit.

Theodore Roosevelt said, "The Nation behaves well if it treats the natural resources as assets which it must turn over to the next generation increased; and not impaired in value." Water pollution in this country is a constant threat which must be controlled if we are to maintain an adequate supply of safe, clean water for home, for agriculture, for industry, and for recreation.

In order to increase the general awareness of the need for pollution control and to aid communities in developing their own control programs, the Division of Water Pollution Control has prepared this kit of materials designed for local leaders of civic clubs, women's clubs, sportsmen's groups, and the like. Included in the kit are a series of six background readings entitled "The Living Waters," covering the uses of water and the importance of pollution control. A "Chairman's Guide" gives suggestions on discussion techniques and on the use of motion pictures, panel discussions and speakers in local meetings, and provides sources of information for community leaders, including the names of all State water pollution control agencies.

Three publications issued earlier have been incorporated into the kit: "The Fight To Save America's Waters," a story of public health and conservation featuring the familiar comic strip character, Mark Trall. "Clean Water Is Everybody's Busi-

ness" presents a graphic review of the water pollution problem and how it affects various aspects of our daily lives. The third publication, "Water Pollution in the United States," gives a more detailed description of the water pollution problem, and a discussion of the costs and responsibilities for control programs.

A Bibliography of Toxoplasmosis and *Toxoplasma Gondii*.

By D. E. Eyles and J. K. Frenkel. Public Health Service Publication No. 247. 1952. 47 pages. 20 cents.

Toxoplasmosis has been recognized as a human disease for little over a decade; it is therefore possible for the interested researcher to become acquainted with most of the published material on the subject. The authors of A Bibliography of Toxoplasmosis and *Toxoplasma gondii*, who have had occasion to study the literature and have collected reprints, photoprints, or translations of most of the papers, have covered the literature through 1951. A few 1952 papers are included. The earliest paper cited is by Laveran—the date, 1900. This was followed in 1913 and 1915 by other papers by the same author, but 20 years elapsed before more than an occasional paper appeared in the literature. The bibliography contains 920 titles.

In their preface, the authors state that because of time limitations, it was not possible to be critical in selecting titles. Some papers dealing with organisms erroneously assigned to *Toxoplasma* by their authors are included, and there are references to a few case reports in which the evidence that *Toxoplasma* was involved is scant or poor. A number of papers which do not refer to *Toxoplasma* are included as they are now considered to deal with this organism.

In preparing the bibliography, full citations are given if the information is available, and references to abstracts have been listed with the citation of the original whenever possible.

Milk Ordinance and Code. 1953 Recommendations of the Public Health Service.

Public Health Service Publication No. 229. 1953. 242 pages. 75 cents.

The twelfth revision since 1924, the 1953 edition of the Milk Ordinance and Code recommended by the Public Health Service takes cognizance of the notable progress in milk sanitation since 1939.

Like the preceding editions, this revision has been developed with the assistance of the U. S. Department of Agriculture, the Food and Drug Administration, State health and agriculture departments, local health departments, the dairy industry, educational institutions, and individual milk sanitarians.

The book is presented in a form which can be adopted as an ordinance or other legal instrument. Part I contains an abridged form of the recommended milk ordinance suggested for local adoption in States where adoption of ordinances by reference to published standards is considered legal. The Council of State Governments has prepared a model law, "Milk and Food Codes Adoption Act," published in "Suggested State Legislation Programs for 1950."

Part II is the complete ordinance. It details the definition of milk and milk products, the issuing of permits, standards for labeling, inspection, examination, grading, and grades of milk. Section 11 regulates milk and milk products from points beyond the limits of routine inspection.

Part III contains the interpretative code, which together with part IV is to be used as the legal interpretation of the ordinance. It repeats the provisions of part II and gives the reasons for each requirement.

Part IV consists of nine appendices containing detailed explanatory material and standards formerly used in the code, but now transferred to provide a condensed reference to essential detail not

routinely used. The appendices are an integral part of the code.

On several major and minor questions, the ordinance offers two or more choices. A "degrading" and a "nondegrading" form for enforcement are given. Among other items of choice are: use of reduction tests instead of plate or direct microscopic counts where suitable laboratory facilities cannot be provided; use of a compliance standard of 3 out of 4 samples rather than logarithmic or arithmetic averages of 4 samples.

The Public Health Service is co-operating in a voluntary program of certification of interstate milk shippers. The model ordinance discourages the use of public health regulations to establish unwarranted barriers against acceptance of high-grade milk from other milksheds.

The program of interstate milk certifications was supported by the Committee on Agriculture and Forestry of the United States Senate which "strongly recommended that the Milk Ordinance and Code of the Public Health Service should be used as the minimum standard for the sanitary rating and acceptance of interstate milk shipments."

Home Accident Prevention—A Guide for Health Workers.

Public Health Service Publication No. 261. 1953. 75 pages. Information concerning the availability of this publication can be obtained from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Accidents in the home in 1951 accounted for an estimated total of 28,000 deaths, 110,000 individuals permanently disabled, and 4,200,000 persons temporarily disabled. Because this loss of manpower and the drain upon medical facilities can be prevented, the public health profession is being called upon to take the leadership in developing home accident prevention programs.

In response to numerous requests from educators for assistance in introducing home accident prevention

materials in the training of professional public health workers, this booklet has been prepared as a guide for discussion of the problem.

In 13 sections, this publication outlines the chief problems of home accident control, the major causes of home accidents, and recommended preventive measures. The major causes of accidents covered are: falls, fire, hot surfaces and hot liquids, poisons, gases, toxic vapors, and insecticides, electricity, cutting and piercing instruments, firearms, and lifting, carrying, and lowering. In addition, there are outlines for discussion of the general problem, the epidemiological aspects of accidents, environmental hazards, and human and age factors. Selected references and lists of visual aids are contained in the appendixes.

Cancer Illness Among Residents of Philadelphia, Pa.

Cancer Morbidity Series No. 10, Public Health Service Publication No. 244. 1952. 43 pages; tables, charts. Individual copies available on request to National Cancer Institute, Public Health Service, Bethesda 14, Md.

This publication, the tenth and last of the Cancer Morbidity Series, reports that, as in most of the other cities studied, cancer is apparently increasing among the residents of Philadelphia, Pa.

According to a survey made in 1948, the incidence rate for cancer was 26 percent greater than in 1938, while the prevalence rate was up 21 percent. The greatest increase noted was for cancer of the bronchus and

lung, for which the incidence rose 101 percent in the 10-year period.

Approximately half of the cancer cases diagnosed in 1948 were discovered while localized at the site of origin; 2 out of 10 were not diagnosed until remote tissues had become involved. The fact that less than two-fifths of breast cancer cases—an accessible site—were diagnosed while localized points to the need for improvement in case-finding techniques for accessible as well as inaccessible sites, the report indicates.

The first nine studies in the Cancer Morbidity Series covered the Atlanta, New Orleans, San Francisco, Denver, Pittsburgh, Chicago, Dallas, Birmingham, and Detroit areas. A summary containing geographic comparisons, interpretations of apparent national trends, and special analyses will be issued at a later date.

Small Plant Health and Medical Programs.

By Margaret C. Klem and Margaret F. McKiever. Public Health Service Publication No. 215. 1952. 213 pages; tables. 50 cents.

This publication has been prepared to meet requests for current information on small plant health and medical programs and is designed for employers who wish to establish in-plant health programs and for labor, professional, and other groups that have a special interest in employee health.

The report is concerned primarily with the organization and methods of providing health services in in-

dustry by physicians and nurses. It does not cover the technical phases of industrial hygiene engineering and chemistry or the clinical aspects of occupational medicine.

There are three major sections, the first of which, "Employee Health in Relation to Industrial Expansion," describes the need for employee health programs and the trends in the development of major types of health programs. It gives current data on personnel and facilities serving the employees in establishments of various sizes in the United States as a whole, and in selected States and cities.

Section II, "Type and Extent of Small Plant Health and Medical Programs," is concerned with the development of small plant health programs and the costs and accomplishments of such programs. A description of six cooperative programs, four communitywide projects developed under a variety of sponsorships, and four individual small plant programs is contained in the third section. Appendixes contain detailed information that may be of assistance to those responsible for the development and direction of small plant programs. References to general information in the field are also given.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Nutrition Research

Potentialities in Chronic Disease

By WILLIAM H. SEBRELL, Jr., M.D.

HEALTH MAINTENANCE and constructive medicine—two emerging concepts in modern public health—weigh heavily in any consideration of nutrition in light of our aging population and the increasing significance of chronic disease.

We have made great strides against deficiency diseases, such as pellagra, beriberi, rickets, and goiter. While performing our day-to-day task of maintaining and extending these advances, we can now think in terms of constructive or optimum nutrition, with its implications for promoting healthful, productive longevity.

Aging, nutrition, and public health are directly related in various ways. Special feeding problems and nutritional needs of old people are of primary concern, and nutrition problems are common in the treatment of chronic diseases, for example, when digestion is impaired. Closely related is therapy by dietary means, as in diabetes and gout. An-

other—and fundamental—aspect is chronic disease research, a major objective of which is a better understanding of metabolism.

In much of this effort, primary attention is given to the complex interrelation of nutrients with enzymes, hormones, and other metabolic agents. Encouraging progress has been made, but our knowledge is still fragmentary and requires much supplementation. In other research not directly concerned with nutrition, knowledge and techniques are being developed that can be readily applied in the nutrition field.

Obesity and Chronic Disease

An important but little understood link between nutrition and chronic disease is obesity—a major problem called sharply to attention by actuarial experience, and now being investigated in several laboratories. About a quarter of the adult population is sufficiently overweight to impair health.

No better understood than the role of obesity in disease is the relation between obesity and the aging process. As we pass through the middle years, the percentage of body fat usually rises, though the overall weight may remain the same. Thus, among groups of standard weight, fat may comprise only 10 percent of the body weight in younger men, as compared with 21 percent in older ones. The prevalence of obesity increases to about age 40 for men and 50 for women, and declines after age 60. This decline is due not only to loss of fat, but also to the loss of fat people.

Dr. Sebrell is director of the National Institutes of Health, Public Health Service. On June 22, 1953, he spoke before the Institute of Food Technologists at its 13th annual meeting in Boston on "The changing age pattern of the American population, with its implications in the field of public health." This is a portion of his paper—that dealing with metabolic investigations related to chronic diseases. The full text, with citations, is scheduled for publication in Food Technology for September under the title of "Aging, Nutrition, and Public Health."

*The wee son turned the shining future up;
His father plowed the green past under.*

—From *Man and Boy*, by Alma Robison Higbee

Dr. Goldberger and Dr. Sebrell

The Joseph Goldberger Award in Clinical Nutrition is presented by the Board of Trustees of the American Medical Association for outstanding and sustained work in the field of clinical nutrition. The 1952 award, which includes a gold medal and a check for \$1,000, made possible by a grant from the Nutrition Foundation, was given in December to Dr. William H. Sebrell, Jr., Assistant Surgeon General of the Public Health Service and Director of its National Institutes of Health. He was selected because of his outstanding work in the field of riboflavin deficiency, in pellagra prevention with Dr. Goldberger, and for his continued work in the field of clinical nutrition. The previous recipients of the award were Dr. Randolph West and Dr. Fuller Albright. In response to the presentation of the award, Dr. Sebrell discussed the present status and the future of nutrition as it relates to medicine in America. His remarks were published in the *Journal of the American Medical Association*, May 2, 1953, pp. 42-44.

On pages 737-746 are two recent papers by Dr. Sebrell—one dealing with nutrition research, the other with public health aspects.

JOSEPH GOLDBERGER'S life (1874 to 1929) "was a Horatio Alger experience common to other great Americans. He was born on a peasant tenant farm in Czechoslovakia in 1874 and brought to New York City when he was 7," according to Williams (p. 279, *The United States Public Health Service, 1798-1950*). "For the early part of his life he delivered groceries for his father on the lower East Side. At 16, he decided on a course of civil engineering, but 2 years later switched to medicine after he heard the Horvey Lecture given by a Bellevue Hospital College physician. In 1895 he graduated second in his class at Bellevue, where he had acquired a reputation as a holder of routine but a master of case history writing. To him every case was a great and absorbing mystery, the solution an exciting challenge. After a 2-year try he decided that private practice was not his field and he entered the Marine Hospital Service. He performed brilliant and dangerous work on typhus fever, operating always at the epidemic scene. He also made important studies of the Mexican form of typhus fever and of yellow fever. But the chance to exercise his talents, his greatest contribution to humanity, came when he was put in charge of pellagra investigations."

Continued from page 737

The fact that obesity is correlated with aging and chronic disease does not in itself imply a causal relation. Unknown etiological factors may be common to these conditions. In various studies, however, caloric restriction has prevented cancer in mice, prolonged greatly the life of rats, and reduced the signs of diabetes in humans. Moreover, striking decreases in the incidence and severity of diabetes and hypertension accompanied undernutrition and loss of weight in certain European countries during both World Wars. It may reasonably be assumed then that practical advances against obesity would have far-reaching effects upon public health.

This problem is fertile for research. We should like to know, for example, what benefits in longevity accrue to the middle-aged person who reduces and maintains the reduction. We need clarification of the mechanism, psychological or metabolic, that leads to overeating.

Wading through the wilderness of conflicting theories as to the cause of pellagra, and in the face of those who claimed to have proved that it was infectious in origin, Goldberger's first theory, which he announced in 1914, was that pellagra was due to a deficiency in diet. This he proceeded to prove conclusively and devised ways in which the disease could be prevented and cured. Even so, he did not discard the possibility that pellagra might have an infectious element until he proved to his own satisfaction that this could not be true. This he did by injecting blood from patients with pellagra into himself, his associates, and even into his own wife. Furthermore, he made pills from the intestinal discharges and the skin rash scales from pellagrous subjects and ate them as further proof that no infectious agent was involved.

Later he sharpened his ideas about the dietary origin of pellagra to include the concept that a "vitamine" deficiency was involved. This was a quite new concept in disease etiology since Funk had coined the name "vitamine" only in 1911. Later his ideas shifted to include the possibility that an amino acid deficiency, specifically cystine and tryptophan, was causative. Both of these theories were proved after Goldberger's untimely

death, although it was not until 1945 that the amino acid tryptophan was clearly implicated.

Never one to form a theory and fail to test it, Goldberger and his associates reported in 1922 on tests with cystine and tryptophan, although their claims for therapeutic value were very conservative. For reasons unknown, he never reported on some dramatic results which he and his associate Tanner obtained with tryptophan alone. Nicotinic acid was not known as a vitamin during his lifetime so it could not be tested.

Goldberger's influence on nutrition research continued long after his death and continues even today. The dog, which he introduced and established as a tool in pellagra research, is still used today. The dietary data which he and his associates collected have been used recently to recalculate the human requirement for nicotinic acid.

Not the least of his amazing abilities was his capacity to gather brilliant associates who ably continued the work after his death. His career in research was marked by courage, rare intellectual insight, wisdom, and perseverance. In the words of Dr. Arthur M. Stimson: "He illuminated everything he touched and won the admiration and affection of his associates."

—JAMES M. HUNDLEY, M.D.

We should define the role of heredity—a primary factor in the obesity of certain strains of mice. And we may hope that such knowledge will improve means for controlling obesity through public health programs.

Fat Metabolism and Atherosclerosis

This subject of obesity provides a point of transition to the role of fat metabolism in the development of cardiovascular diseases. Among these is atherosclerosis, the most serious form of hardening of the arteries, which causes 9 out of 10 heart attacks and seriously disables hundreds of thousands of persons. This is a type of arteriosclerosis in which the lining of the artery thickens and pushes inward. Deposited cholesterol, a fatlike substance, is a part of this growth.

Observations on patients following weight reduction have shown a decline in circulating cholesterol of the type suspected in atherosclerosis. To what extent the lower cholesterol level

is due to reduced fat ingestion rather than reduction of weight has not been determined.

Research on atherosclerosis is proceeding along many lines. Most investigators, however, work from the hypothesis that the body's fat-handling system plays a part in the development of the disease. Not only have abnormal cholesterol-bearing molecules been found in the blood of sclerotic patients, but some animals on high cholesterol diets develop sclerotic lesions.

Investigators at the National Institutes of Health recently identified a "clearing factor," which diminishes the cloudiness of blood occurring after a fatty meal. In normal persons this condition clears automatically within a few hours, but in others it persists, possibly leading to atherosclerosis. The clearing factor not only eliminates the cloudiness, but appears to break down the abnormal cholesterol-bearing molecules that are particularly suspect.

The fact, however, that the body readily

synthesizes cholesterol from simple, ever-present substances compels caution. Moreover, we do not yet know whether the dietary level of the substance is of practical significance. Cholesterol metabolism involves such nutrients as choline, other B vitamins, and some amino acids; and various nutritional deficiencies affect the deposition. For persons with atherosclerosis, the best diet known at present is a balanced one, such as normal people require. If other problems, such as hypertension, are involved, a special diet may be indicated.

Cancer and Nutrition

Cancer is another chronic disease in which the science of nutrition is contributing valuable information. Dietary manipulations have been shown to exert pronounced effects on cancer causation in animals. Caloric restriction prevents or delays the appearance of various tumors; and restriction of certain amino acids gives similar results. Choline deficiency, on the other hand, induces liver cancer in the rat. These observations have no immediate practical value, since the preventive diets abolish breeding capacity and choline occurs in a wide variety of foods. Such findings, however, are important leads for further research.

In human beings, cancers already established have shown little response to dietary alternations; but in animal experiments, alternate restriction and supply of a vitamin, such as riboflavin or pantothenic acid, has appreciably prolonged life. Vitamin antagonists have produced similar effects: in some children, chemical antagonists to folic acid, such as aminopterin, have been of temporary benefit in leukemia. Recent advances in leukemia concern certain pyrimidine compounds. When administered to animals, these drugs in combination with a folic acid antagonist appear to inhibit neoplastic growth more than antifolics alone. For nutritionists, the exploration of such antimetabolites offers rich opportunities for extending knowledge of normal and abnormal growth.

Bone and Joint Diseases

The study of arthritis, the principal crippling disease, has been hampered by lack of a method for producing the disease in experimental animals. Recently, however, several investi-

gators have produced arthritic changes by dietary means.

At Washington University in St. Louis, a condition resembling osteoarthritis was induced in mice of a highly inbred strain. A high fat diet was fed to one group, a high protein diet to another. The mice that received the fat-enriched diet showed an acceleration of skeletal aging and an increased incidence of osteoarthritis, whereas protein enrichment retarded aging of the joints and delayed the onset of joint disease.

Other groups of workers, one at Kansas City College and another at Cambridge University, report a disease in vitamin-C-deficient guinea pigs that resembles rheumatoid arthritis. It is interesting that these joint changes can be prevented with cortisone.

A recent advance now being applied clinically concerns osteoporosis, a brittle condition of the bones due to decalcification. It is primarily a disease of the aged, but may occur at any age as a late phase of arthritis. At the Russell Sage Institute of Pathology, osteoporosis is being treated successfully with the metal strontium. After maximum calcium storage, strontium can still be stored in the bones. Maximum retention of both minerals is achieved with the aid of auxiliary agents—vitamin D and sex hormones. This, as well as the fact that osteoporosis often results from ovarian insufficiency, clearly suggests a relation between nutrition and hormones for which we have no explanation.

Nutrition science, using new biochemical approaches, offers much promise against diseases of the bones and joints. Even the study of an inorganic nutrient such as calcium presents attractive possibilities. The skeleton is now regarded as a living tissue, particularly in view of tracer studies showing that calcium enters and leaves the skeleton with considerable rapidity. Little is known, however, about the regulation of calcium metabolism. How, for example, is calcium mobilized to the area of a tuberculous lesion? In leprosy, though a bacterial disease, why do entire bones sometimes disappear as a result of resorption? Explanations of such metabolic disturbances could aid in the prevention of arthritic deformity.

Research for Optimum Nutrition

Nutrition science has made great strides in the past, but the opportunities for further progress are limitless. Long-term investments in fundamental research represent an approach historically proved to offer the best returns in the long run. There is a constant exchange, of course, between basic and applied science. Research in nutrition, applied as well as fundamental, will help workers throughout the world in promoting health and long life.

A constructive approach requires that we strive to attain, and to maintain, optimum health while repairing damage. Fortunately, the population as a whole has lost much of its complacency concerning nutrition. Food technology, through food fortification, increased availability and palatability of foods, and other innovations, is a major aspect of the public health approach through which the need for

specific nutritional therapy may some day be eliminated. The human body is remarkably adaptable, and inherent abnormalities of digestion and metabolism may lead to compensatory dietary practices. Unfortunately, however, the contrary is frequently the case; selection and consumption of food often obey a misleading appetite, and the result may be damage and disease.

Nutrition science is only beginning its venture into gerontology and the major chronic diseases. Whether substantial contributions are achieved in the near future depends largely on the cooperative efforts of many individuals and groups. No longer is scientific progress by lone investigators the rule, as in the days of Pasteur and Ehrlich. Many disciplines must coordinate their attack. Nutrition research and theory must be converted to food therapy, nutrition knowledge, to public health gains.

Enrichment

a Public Health Approach to Better Nutrition

By WILLIAM H. SEBRELL, Jr., M.D.

WE ARE inclined in these modern times to take our knowledge of nutrition for granted and to underestimate the importance of its application. Consider for a moment the problem of malnutrition in earlier days. Vasco de Gama, in his search for a water route to the East, rounded the Cape of Good Hope and returned with only a third of his crew, the rest having died of scurvy. At one time the channel fleet of the British Navy could not be manned because of the prevalence of scurvy among the crews. In the late 19th century, 40 percent of the seamen in the Japanese Navy died of beriberi; and in Italy at about the same time, the reported cases of pellagra exceeded 104,000. One by one, these and other serious diseases re-

sulting from specific dietary deficiencies have yielded to science.

The progress of nutrition research, however,

Dr. Sebrell presented this paper at Toronto on January 26, 1953, as Canada inaugurated a program of flour and bread enrichment. Speaking before the First Nutrition and Enrichment Conference of the Baking and Milling Industries, he characterized the Canadian enrichment program as "one more forceful blow in the prevention of malnutrition . . . further indication of the increasing role of enrichment in the health and strength of nations." His discussion, here somewhat condensed, appears in full in The Canadian Hospital for June 1953.

is only part of the story of effort in the nutrition field. The complete picture includes what might be termed the public health movement—the application of nutrition knowledge through industry, agriculture, education, government, and, of course, the medical profession. In this movement, an important trend in Europe and North America has been a broadening of the attack to extend preventive measures to successively larger groups of people.

Early Applications

Available knowledge prior to World War I was used mainly for the prevention or alleviation of dietary deficiency diseases in the individual. Citrus fruits and juices were fed to seamen, and later to children, to treat and prevent scurvy; cod liver oil was used in treating rickets; extracts of rice polishing, in beriberi. The next step, an organized public health approach, was the planned distribution of preventive dietary supplements, such as cod liver oil, butter, and iodized salt. Meanwhile, the isolation of vitamins progressed; and just prior to World War II, it became practical to improve staple foods with synthetic nutrients as a means of preventing dietary diseases in large populations.

In the United States, on a growing scale, vitamin D was added to milk and vitamin A to margarine. Thus, the principle being used in the control of goiter with iodized salt—the fortification of food—was extended to rickets and vitamin A deficiency. Early in 1941 the same broad approach was applied to the prevention of beriberi, pellagra, ariboflavinosis, and iron-deficiency anemia, when enriched bread and flour were introduced.

Public preference for highly refined foods had left the American diet deficient in many important respects. For example, the patent milling process, by removing most of the germ and bran shorts from flour, reduces the thiamine content about 90 percent and the niacin, riboflavin, and iron 70 to 85 percent. White bread and refined sugar and fats are widely preferred for taste, appearance, and durability. Together they furnish a large proportion of our calories. This resulted in less than satisfactory amounts of essential nutrients per capita and

led inevitably to dietary diseases, especially in poorly fed sections of the population.

The enrichment of bread and flour had therefore received the enthusiastic endorsement of the Nation's foremost nutrition scientists, including the American Medical Association's Council on Foods and Nutrition and the National Research Council's Food and Nutrition Board. With the advice of these groups, the Food and Drug Administration established standards for enriched wheat products, permitting specified amounts of the four nutrients, thiamine, niacin, riboflavin, and iron. Certain other substances, such as calcium, vitamin D, and wheat germ, can also be added, but this has not been done on a wide scale. Calcium and other nutrients are often supplied in bread through use of dry milk solids, a practice that should be extended.

Status at Pearl Harbor

By the time the country entered World War II, the enrichment of flour and bread had become well established. Within another year about three-quarters of the bakers' white bread and almost all family flour was enriched on a voluntary basis. A further step in the application of nutrition knowledge was now feasible—nationwide control of specific dietary diseases; and a program to that end was soon launched. During periods of war, foods that are costly to produce tend to become scarce, and greater dependence is placed upon cereal products, the least expensive foods in terms of man-hours and acreage. Consequently, it was apparent that cereals as an important part of the national diet must contain essential nutrients.

Serious consideration was given to the possible use of long-extraction flour, which retains some of the vitamins and mineral-rich portions of the wheat. Some reasons against requiring the product, besides the general preference for white flour, were its perishability, its limitations for pastry, and the dependence of the animal food industry upon the residues of patent milling. Moreover, it was believed that the prohibition of white bread and flour would be difficult or impossible to enforce in the United States. There was also the success achieved with voluntary enrichment, as well as the fact

that enriched products were better supplied with the nutrients in question—an important health consideration.

In January 1943 the Federal Government issued war food order No. 1, requiring the enrichment of all bakers' white bread with thiamine, niacin, riboflavin, and iron. Subsequently, the nationwide nutrition movement brought about improved agricultural practices, better nutrition education, a national school lunch program, and advances in food handling, preservation, and distribution. Since October 1946 when the war food order ceased to be effective, enrichment of bread and flour has not been required by Federal regulation, but more than half the States have passed laws making enrichment mandatory. In the remaining States, voluntary enrichment is being continued extensively, according to recent surveys by the industry.

Assessment After a Decade

After nationwide practice of more than 10 years, what have been the health gains due to better nutrition, and to what extent are they attributable to the enrichment program? What, if any, have been the harmful effects? What is the future of food enrichment as a means of attacking malnutrition throughout the world?

Unequivocally, we can say that there is no evidence of harm from the program, nor reason to expect it. If the diet contains slightly more than the required amount of a nutrient, the excess is simply excreted. These statements apply also to the products commonly fortified with iodine and vitamins A and D. There is a wide margin of safety between recommended and harmful levels.

As to health gains, on the other hand, there is ample evidence of the efficacy of the nutrition program and every reason to ascribe much of the success to bread and flour enrichment. No more dramatic history of health progress could be cited than that of pellagra in the United States. In the 1920's and 1930's, this was our most serious deficiency disease.

Pellagra and Niacin

Pellagra results from a diet low in two nutrients, either of which will prevent it—the

vitamin niacin and the protein component tryptophan. Mild cases are much commoner than extreme cases, and mortality rates reflect only a small proportion of the pellagra problem. In a region of high prevalence, at least 33 cases per death were found in 1917, before control measures were instituted. At one time, an estimated 200,000 were afflicted with pellagra in the United States. In 1928, at the height of reported mortality, there were approximately 7,100 pellagra deaths, or 6 per 100,000 population. Nearly 98 percent of those occurred in southern States where most of the available land was used for nonfood crops, such as cotton and tobacco.

For the past 25 years, the death rate from pellagra has shown a general downward trend. This is attributable not only to the national nutrition program, but also to better medical treatment, shifting of the population, extensive changes in agricultural practices, and gradual economic improvement in the south through the establishment of industry there.

It is interesting to note the pellagra mortality at key points in the nutrition program. By 1937, the year niacin was isolated, pellagra mortality was about half that of 1928, or 2.5 per 100,000. Cures with niacin were reported that year by several clinicians, and thereafter the decline was more rapid. In 1943, 2 years after niacin-enriched foods appeared on the market, the rate was 1; by 1950 it had dropped to 0.2, representing an unprecedented low of 260 reported deaths in the entire country.

In North America, mortality data do not reflect the true health importance of the deficiency diseases, since very few affected persons die. It is the number of cases—the people limited in their capacity to work and enjoy life—with whom we are especially concerned. Nearly all of the estimated 200,000 cases of 20 years ago were in the south. In contrast, among 10,000 recent admissions to the Hillman General Hospital in Birmingham, Ala., not a single pellagra was found—and this, at one of our permanent pellagra research centers in an area where the disease was once rampant.

At the Cincinnati General Hospital, where 34 cases were diagnosed in 1939, only 1 case was seen from 1946 to 1948. If enrichment had done

nothing but help control this one disease, it would have paid for itself many times over in lives saved and people rehabilitated.

Even among chronic alcoholics, once commonly afflicted, pellagra has become rare. In 1948 and 1949, the Army Medical Nutrition Laboratory examined approximately 16,000 alcoholic inmates of the Chicago House of Correction and found only 2 with pellagra, 3 with ariboflavinosis, and 1 with possible beriberi. The decline of those diseases among alcoholics clearly dates from the introduction of enrichment.

B-vitamin Deficiencies

Beriberi is a disease resulting from lack of thiamine, another vitamin of the B group. Like other deficiency diseases, beriberi has no geographic limitations, though more than 90 percent of the cases are reported among rice-eating peoples. How serious it can be as a public health problem is shown by the fact that in the Philippines in 1948 beriberi was second only to tuberculosis as a cause of death. Small outbreaks have occurred in such places as Australia, Iceland, and Labrador. In the United States, Great Britain, and other western countries, beriberi has been frequently reported among chronic alcoholics and the inmates of institutions; but it is not an important cause of death among peoples consuming a variety of foods. In its less severe forms, however, there was evidence that thiamine deficiency was sufficiently prevalent in the United States to warrant addition of the vitamin to flour and bread.

Ariboflavinosis—riboflavin deficiency disease—is reported frequently in various parts of the world. It often occurs in conjunction with other B-vitamin deficiencies, especially pellagra. Ariboflavinosis was not recognized as affecting humans until 1939. As a result, the incidence in the United States was not accurately estimated, but there is no doubt of its former prevalence.

Like pellagra, these B-vitamin deficiency diseases—beriberi and ariboflavinosis—have declined in the United States as a result of improved nutrition to which enrichment has demonstrably contributed.

General Effects of Enrichment

While the demonstrated prevention of specific deficiency diseases is the real test of enrichment, other evidence of its effect on the nutritional status of the population should not be ignored. Over the past 10 or 15 years, there has been a general elevation in the nutritive value of our national diet. This means primarily a higher vitamin, mineral, and protein intake. As shown in studies by the U. S. Department of Agriculture, the most striking increases have been in thiamine, niacin, riboflavin, and iron—with a sharp rise beginning about 1941, when enriched bread and flour were introduced. In 1945 and 1946, the peak years of per capita consumption, these four nutrients exceeded prewar levels by a third to a half.

The average American in 1945, as compared with what he would have received without enrichment, obtained in his food 27 percent more thiamine, 19 percent more niacin, 12 percent more riboflavin, and 17 percent more iron. The benefits were greatest among the lower income group, whose diet is poorest and incidence of deficiency diseases highest.

Thus, we are able to trace various specific health gains due to better nutrition and even to assign a considerable measure of that progress to the enrichment program. Other advances in health are undoubtedly associated with the nutrition movement, but their contribution is harder to prove. Maternal and infant deaths, for example, have declined to unprecedented levels, and nutritional changes have been significant. Similarly, there have been appreciable increases in growth rate and stature. Downward trends in mortality from infections, particularly tuberculosis, have paralleled the elevation of nutritional status. In short, the benefits of improved nutrition have exceeded our most optimistic expectations.

Problems Ahead: Chronic Diseases

By no means, however, does all this imply that our national diet is now perfect, nor that malnutrition in the United States is a thing of the past. I have discussed only the advances, the favorable trends. Many problems still confront us, some of which mount in significance

as various factors lengthen the life span and increase the number of older people in the population.

One such problem is our high mortality from chronic diseases frequent among the aged, such as the cardiovascular diseases, cancer, diabetes, and cirrhosis of the liver. Another problem, the extent of which is uncertain, is that of borderline dietary deficiencies—conditions presenting an indefinite clinical picture, but nevertheless one of suboptimal health.

With regard to the problems attacked through enrichment, we know that anemia, by generally accepted standards, is still widespread in the United States, especially among women. This is thought to be largely nutritional in origin. The commonest form of anemia—secondary, or hypochromic—is attributed to iron deficiency; but the incidence has shown little change, despite the increase in the average consumption of iron. Does this mean that the problem is overestimated because of an unrealistic health standard, that iron is poorly utilized, or that iron deficiency is not responsible for the condition? Only further research can provide an answer.

There are many other important research problems in nutrition. Our approach to these must remain broad. The history of science shows conclusively that the long-range point of view—the emphasis upon fundamental investigation, often with little promise of practical reward—is the most productive approach in the long run. Practical applications of basic knowledge will suggest themselves.

For the most part, the remaining nutrition problems require further research and intensive education. Enrichment should certainly be continued and, along some lines, extended. Not only would a relaxation of that effort permit a relapse of nutritional status, with a high probability of increasing deficiency disease, it would also undermine our nutritional foundation, the bulwark of cheap staple foods—bread, flour, milk, salt, margarine, and so forth—upon which the Nation's health would depend in an economic or other calamity. The National Research Council has described enrichment as "low-cost insurance against certain nutritional ills."

Nutritionists and allied workers in the United

States appreciate the importance of developing their programs in full recognition of world nutritional needs. Today, serious world problems critically involve us all—problems that often reflect the ratio of food supply to population. Established techniques intensively applied can often remedy the local shortage of a vitamin—as shown recently in the Philippines, where rice enrichment and other measures reduced beriberi deaths in an experimental zone by 90 percent or more. The successful expansion of this program in the Philippines would be a major public health advance for that country.

Enrichment, Education, Research

Enrichment is a powerful weapon against malnutrition, but it must not become the sole or final effort. Nutrition research must be intensified; and sound programs of nutrition education—the essential link between professional knowledge and the improvement of food practices—must be vigorously pursued.

These are aspects of the public health program in nutrition to which industry and government can contribute, as they have done notably in the past. Let me stress the necessity of cooperation between industry and government in this movement. It has been our experience that businessmen are deeply interested in the Nation's health, that they recognize its great importance and that they want to be helpful and to do the right thing. They also have their feet on the ground and properly act only when strongly convinced. Such cooperation is highly productive in the field of education. Here, industry can bring to bear effective techniques and attractive media, which government agencies cannot obtain. Whenever government and industry participate in a sound program of nutrition education, as they have done in the United States, material progress in public health can be expected.

Nutrition education, as its main objective, should seek to establish public demand for an adequate diet, taking into account a wide range of consumer incomes. The physician, health officer, nurse, teacher, and other key persons in the community must be prepared to guide individuals and institutions in selecting the right foods; and for this, they must be skilled in the

practicalities of feeding—food values relative to cost. In commercial advertising, a greater effort should be made to show the proper relation of the promoted product to good nutrition as a whole. Finally, community leaders, advertisers, nutritionists, and others in the role of educator should focus primarily upon the housewife, who selects and prepares the meals and guides in the formation of food habits.

Sound food habits must always be the major objective. It is unlikely, however, that enrichment will ever be entirely superseded by informed food selection, since food values vary seasonally and geographically, and selection to some extent is economically determined. The modern attack upon malnutrition should be spearheaded by enrichment, backed by education, and controlled by research.

CIRCULARIZATION

Of PHR Free Mailing List

Early in October *Public Health Reports* will send a mailing list circularization inquiry to all addresses on its official and free mailing lists—not, however, to paid subscribers.

Required by the Joint Congressional Committee on Printing, this circularization necessitates return of a special card confirming correctness of the address and number of copies of *Public Health Reports* sent each month. Health departments, teaching institutions, libraries, and others will want to devote special attention to the circularization inquiry, as the mailing list is composed for the most part of office and position titles, rather than of individual names.

Watch for the special postal card. Complete it fully and return it promptly. Failure to respond by the date specified on the card sent each addressee will result in removal of the name from the mailing list.

Agglutination of *Treponema Pallidum* In Syphilitic Serums

By CHARLOTTE P. McLEOD, Sc.D., and HAROLD J. MAGNUSON, M.D.

NUMEROUS unsuccessful attempts have been made to demonstrate specific agglutination of pathogenic *Treponema pallidum* in syphilitic serum. Most such attempts have met with failure due to the tendency of the organisms to agglutinate spontaneously. Interest in the subject was revived by the report of Tani (1) that Antiformin-killed spirochetes showed no such spontaneous clumping, but were agglutinated in syphilitic serum after an incubation period of 24 hours; and that organisms so treated provided satisfactory antigens for the serodiagnosis of syphilis. More recently, specific agglutination of *T. pallidum* was reported by Gain (2) who obtained antigens which showed no spontaneous agglutination from syphilomas of X-irradiated rabbits; and also by Hardy and Hollander (3) who prepared satisfactory heat-killed spirochete suspensions from lesions of syphilitic rabbits treated with cortisone.

The agglutination technique described in the present paper was devised by bringing together the findings of two separate lines of investigation. The experiments of Tani (1) were confirmed and extended. At the same time, there was in progress a study of complement in the

Treponema pallidum immobilization test (TPI). In testing the fresh serum of various animal species for complement activity, it was noted that fresh steer, or other bovine, serums caused disappearance rather than immobilization of the spirochetes, and also caused agglutination of sensitized sheep cells. It was then found that the agglutination of *T. pallidum* in syphilitic serum was greatly enhanced by the addition of fresh steer serum. These effects of fresh steer serum in both the TPI test and the agglutination test were due to the presence of congenitinin (4) in addition to complement.

By means of the agglutination technique with fresh steer serum the presence of syphilitic antibody may be demonstrated in a test which utilizes killed spirochetes and is completed in only 2 hours. It will be shown that this reaction appears to have a specificity comparable with that of the TPI test, and sensitivity many times as great.

Methods

The Nichols strain of *T. pallidum* was employed in all experiments. Serum samples from normal or syphilitic human donors were stored at -20°C . until tested. Fresh steer or fresh guinea pig serum was distributed in suitable amounts in small containers and stored in a CO_2 chest at -76°C ., and samples were not thawed until immediately before use. The steer serum was frozen on the day the blood was collected; the guinea pig serum usually was frozen on the day following collection.

TPI tests were set up by the method of Nelson and Mayer (5) with modifications and controls

Dr. Magnuson is director of, and Dr. McLeod is a bacteriologist with, the Venereal Disease Experimental Laboratory, Public Health Service, at the School of Public Health, University of North Carolina, Chapel Hill, N. C. Assisting in the technical details of the study were Peggie Stokes, Virginia Willis, and Mary Harris.

previously described (6, 7). Unmodified Nelson's medium (8) was used in titrating serum from patients with untreated primary, secondary, or latent syphilis. Five times the usual concentration of sodium thioglycollate (9) and 5 percent of inactivated normal rabbit serum were added to the medium in all other experiments. Each assay tube contained a total volume of 0.45 cc., which included 0.3 cc. spirochete suspension, 0.1 cc. of undiluted steer or guinea pig serum as complement, and 0.05 cc. of test serum or dilution. TPI assays were incubated for 16 hours at 37° C.

In tests with sheep erythrocytes, suspensions of cells and dilutions of serum were made in physiological saline (0.85-percent sodium chloride). Sensitized cells were prepared by mixing equal volumes of a 3-percent sheep cell suspension and a 1:500 dilution of rabbit amboceptor. (Amboceptor was obtained from the Venereal Disease Research Laboratory, Chamblee, Ga.) Unsensitized cells were similarly prepared with saline instead of amboceptor. Sheep cell suspensions were used in a volume of 0.4 cc. In testing for residual complement in TPI assays or in complement titrations, the tubes were incubated in a water bath at 37° C. for 30 minutes.

In preparing the antigen used in agglutination tests with fresh steer serum, spirochetes were obtained from testicular lesions of rabbits inoculated 8 to 10 days earlier. The testicles showing 3+ induration were sliced in an egg cutter and extracted with 5 to 10 cc. of 0.85-percent sodium chloride per testis. Three such extractions were carried out for 1 hour at room temperature on a rotating shaker. The saline extracts were pooled and centrifuged for 10 minutes at a low rate of speed to sediment the larger tissue particles. The supernatant was then spun for 1 hour in a Sorval angle centrifuge (approximately 20,000 G) to sediment the spirochetes. The supernatant was discarded, and the organisms were resuspended in saline and killed by heating in a water bath at 56° C. for 40 minutes. The suspensions then were further diluted with saline to contain approximately 60 spirochetes per high power field, and were stored at 4° C. Antigens so prepared showed no spontaneous agglutination

during storage periods which lasted for as long as 3 months. However, there often appeared, during storage, a finely granular precipitate in which some of the spirochetes became enmeshed. This material was present to a greater or less degree in the different suspensions, and usually could be removed or greatly reduced by centrifugation.

Agglutination Studies

In preliminary studies, the findings of Tani (1) with Antiformin-killed spirochetes were repeated, and other methods of killing the organisms were investigated. (Antiformin, which contained not less than 6 percent sodium hypochlorite, was purchased from American Antiformin Co., Brooklyn, N. Y.) unwashed spirochete suspensions were treated with Antiformin in final concentrations of 0.1 to 0.25 percent for a period of 30 minutes at room temperature. The organisms then were sedimented by centrifugation and resuspended in saline containing 0.5 percent phenol. One-tenth cubic centimeter of antigen was added to 0.1 cc. of syphilitic serum dilution, and the mixtures incubated in a water bath for 26 to 27 hours at 37° C. Specific agglutination was obtained by this method, and a positive control serum (human pool B) regularly showed 3+ to 4+ agglutination in the 1:32 dilution.

In further experiments, aliquot portions of the unwashed suspensions were subjected to different treatments. One portion was untreated and the spirochetes allowed to die on standing at 4° C. The organisms in the other portions were killed by treatment with Antiformin, by heating at 56° C. for 40 minutes, or by the addition of a final concentration of 1:4,000 Mapharsen, 0.2-percent phenol, or 0.1-percent formalin. Agglutination similar to that with Antiformin-killed antigens was obtained with the untreated, heated, or Mapharsen-killed organisms. All of the phenol-killed antigens showed some degree of spontaneous agglutination, and formalin-killed organisms failed to agglutinate.

Six different saline testicular extracts were used. Four of these provided satisfactory antigens. They were obtained from lesions of rabbits inoculated 7, 9, 11, or 11 to 13 days

earlier. Two extracts obtained from 9-day lesions or from pooled 7- to 14-day lesions were unsatisfactory, showing 1+ to 4+ spontaneous agglutination in all antigens except the formalin killed. The Antiformin-treated antigens showed the least amount of spontaneous agglutination, and the phenol-killed organisms showed the greatest amount.

Use of Fresh Steer Serum

In testing serum from numerous animal sources for complement activity in the TPI test (data to be published), considerable variation was noted in the serum from different species. While none of the serums showed immobilizing activity in the absence of hemolytic activity as measured by the usual rabbit amboceptor-sheep cell system, these two properties were not necessarily present in the same degree. Of particular interest in these studies was the finding that fresh steer serum caused complete disappearance of the spirochetes under the conditions of the TPI test. Also when a syphilitic serum was tested quantitatively with fresh steer serum, the spirochetes which reappeared at the end point of the titration were motile and there was no evidence that immobilization occurred between the stages of disappearance and reappearance. When tested under identical experimental conditions, the "disappearance titer" with steer serum and the immobilization titer

with guinea pig serum were similar after 16 hours' incubation. However, it was found by reading the tests at 6 hours that disappearance proceeded more rapidly than immobilization. Disappearance occurred also when aliquot portions of the suspensions were heated at 56° C. for 40 minutes, and the tests incubated under either aerobic or anaerobic conditions.

In tests for residual complement there was 4+ agglutination but no hemolysis of sensitized sheep cells in tubes containing fresh steer serum. The tubes containing inactivated steer serum showed neither hemolysis nor agglutination. Table 1 shows the results of titrating steer serum against sheep cells as described under "Methods." Both sensitized and unsensitized cells were lysed in high concentrations of fresh steer serum, and were agglutinated in relatively high dilutions. The activity of the fresh serum was slightly higher against the sensitized than against the unsensitized cells. Inactivated steer serum showed no lytic activity, but a low degree of agglutinating activity against only the sensitized cells.

In further experiments with steer serum in the TPI test, it was noted that disappearance of the organisms sometimes took place in control tubes which contained spirochetes plus fresh steer serum, or spirochetes plus fresh steer serum and normal serum. Also a negative end point was not obtained in the titer of the positive control serum. In duplicate assays run

Table 1. Effect of steer serum on sheep cells
[0.4 cc. of serum or dilution + 0.4 cc. of cell suspension]

Dilutions of steer serum	Fresh steer serum				Inactivated steer serum			
	Sensitized cells		Unsensitized cells		Sensitized cells		Unsensitized cells	
	Lysis	Agglutination	Lysis	Agglutination	Lysis	Agglutination	Lysis	Agglutination
0	3+	4+	3+	4+	Negative	2+	Negative	Negative
1:2	1+	4+	±	4+	do	Negative	do	Do.
1:4	Negative	4+	Negative	3+				
1:8	do	4+	do	2+				
1:16	do	4+	do	1+				
1:32	do	2+	do	Negative				
1:64	do	Negative	do	do				
1:128	do	do	do	do				

NOTE: The designations 4+, 3+, 2+, or 1+ refer to the degree of hemolysis, or to the degree of agglutination of cells which resisted hemolysis.

Table 2. Results of TPI tests on serums from patients with suspected biological false-positive reagin tests, using fresh serum from both guinea pig and steer as sources of complement

Total serums tested	Results with guinea pig serum				Results with steer serum			
	Positive	Negative	Doubtful ¹	Nonspecific immobilization ²	Positive	Negative	Doubtful ¹	Nonspecific immobilization
20	3	12	1	4	6	13	1	0

¹ The serum from this patient was positive in the agglutination test.

² Three of these patients were positive and one negative in tests with fresh steer serum.

with the same spirochete suspension and guinea pig complement, all controls were satisfactory. From the results with guinea pig complement it seemed clear that the spirochetes were not sensitized in vivo. It seemed more probable that steer serum contained a natural antibody to *T. pallidum* as well as to sheep cells, and that the effect of this antibody was apparent under the conditions of the TPI test only when the spirochete suspension contained relatively little anticomplementary or other interfering substances.

It was later found when washed killed antigens were used that disappearance of the organisms always occurred in fresh steer serum, and agglutination, but no disappearance, in heated steer serum. Immobilizing antibodies could not be demonstrated in heated steer serum when assayed in the TPI test with guinea pig complement even when twice the usual amount of serum was tested. The presence of "reagin" in steer serum was suggested by a positive Kahn test. However, VDRL and Mazzini tests were negative.

Serum samples from 20 patients with suspected biological false-positive reagin tests were examined by the TPI technique, using both fresh guinea pig and fresh steer serum as sources of complement. The two tests on the same patient were always run in the same assay. Table 2 shows the results of this study. There was agreement between the results obtained with the two methods except in four serums which showed nonspecific immobilization when assayed with guinea pig complement. Three of these serums were positive and one was negative when tested with steer serum. One serum which gave a doubtful result by

both methods was later positive in the agglutination test with fresh steer serum.

Use of Syphilitic and Steer Serums

Spirochete suspensions washed in saline and heat killed, as described under "Methods," were used as agglutinating antigens. In studying the effect of adding fresh steer serum to the agglutination mixtures, it was noted that the organisms disappeared in controls of fresh steer serum, and showed 2+ agglutination in controls of heated steer serum. By suitably diluting the steer serum in saline, these effects were overcome, and sufficient activity remained to greatly enhance the agglutination of *T. pallidum* in syphilitic serum.

In setting up agglutination tests, 0.1 cc. antigen, 0.1 cc. of 1:7 fresh steer serum, and 0.1 cc. of inactivated test serum or dilution were mixed in Wassermann tubes and incubated for 2 hours in a shaking machine at 37° C. In reading the tests, 0.01 cc. of each mixture was measured onto a slide and examined under a 22 x 22 mm. cover slip with the high dry objective.

In reading the tests, consideration was given both to the number of unagglutinated spirochetes per field, and to the proportion of organisms which were agglutinated. This is illustrated in table 3 which also shows a typical titer obtained on pool B, a positive human control serum. There were 20 spirochetes per field with no agglutination in the controls of antigen plus saline, antigen plus active or inactive complement, or antigen plus normal serum with active complement. In the control of heated complement and undiluted pool B, one-half the total number of spirochetes were unagglutinated, and one-half were agglutinated into

small clumps. This was designated as 2+ agglutination.

In the titer of pool B with active complement, there appeared to be complete disappearance of the spirochetes in the undiluted serum. In the 1:10 and 1:20 dilutions, there was 4+, or practically complete, agglutination with only one or less unagglutinated spirochete per field. The agglutinated organisms were contained in a few large, very tightly packed clumps which were usually located by searching the slide with the low-power objective. In the 1:40 dilution, there was an average of two single spirochetes per field, and 3+ to 4+ agglutination. The clumps in this dilution were less tightly packed, smaller, and more numerous than in the two preceding tubes. The 1:80 dilution showed 2+ agglutination with approximately one-half the organisms agglutinated in small- and medium-sized lacy clumps. In higher dilutions, there were 18 to 20 single spirochetes per field, and little or no agglutination.

At the same time pool B was run with fresh guinea pig serum which was active in the TPI test, and a titer only slightly higher than that without complement was obtained. Strongly positive agglutination occurred in the undiluted syphilitic serum after 2 hours' shaking, and in the 1:10 dilution after 23 hours' shaking. In the absence of shaking, agglutination occurred less rapidly with both steer and guinea pig complements.

Experiments were then set up to study the

mechanism by which fresh steer serum enhanced spirochetal agglutination. Pool B was titered as described above with fresh steer serum, with fresh guinea pig serum, and with fresh guinea pig serum plus 0.05 cc. of a 1:3 dilution of steer serum which had been heated for 30 minutes at 56° C. The tests were read after shaking for 2 hours at 37° C. In the titer with fresh steer serum, the 1:40 dilution of pool B showed 3+ agglutination; in the test with fresh guinea pig serum, only the undiluted pool B showed 4+ agglutination; and when tested with fresh guinea pig serum plus heated steer serum, 4+ agglutination was obtained in the 1:40 dilution. The control of undiluted pool B plus heated serum showed only 2+ agglutination. It seems clear from these results that the property of steer serum which enhanced agglutination was congenitally (4).

Using the technique with fresh steer serum, pool B has been titered a total of 24 times, with six different antigens. The reproducibility of the titers was well within the limits of technical error, and different antigens did not vary greatly in sensitivity. The dilution giving 3+ to 4+ agglutination ranged from 1:40 to 1:80 in 13 tests with 2 antigens, and from 1:80 to 1:160 in 11 tests with 4 antigens.

The specificity of the agglutination test is shown in table 4 which contains a comparison of the results of standard serologic tests (STS), TPI, and agglutination tests on serum from 154 presumably nonsyphilitic human donors. The

Table 4. Results of qualitative serologic tests on presumed nonsyphilitic donors

Donors	Total	STS			TPI		Agglutination		
		Positive	Negative	Not tested	Positive	Negative	Positive	Negative	Doubtful
Medical students.....	46			46	0	46	0	43	3
PHL staff.....	29			29	0	29	0	29	0
Hospital patients.....	66	0	66	0	0	66	0	66	0
Hospital employees.....	12	0	12	0	0	12	0	12	0
Blood donor.....	1	0	1	0	0	1	1	0	0
Total.....	154	0	79	75	0	154	1	150	3

Donors included medical students, Venereal Disease Experimental Laboratory staff, hospital patients with diseases other than syphilis, hospital employees, and one blood donor. In DRL tests, there were no positives, 79 serums were negative, and 75 not tested. In TPI tests, there were no positives, and all 154 serums were negative. In the agglutination tests, there was one positive test, 3 doubtful reactions, and 150 negatives. The positive serum was obtained from the one blood donor, and the three doubtfuls, from medical students.

Table 5 shows a comparison of the results of STS, TPI, and agglutination tests on serum from patients with untreated primary, secondary, or latent syphilis. There were serums from 12 cases of darkfield positive primary syphilis. In STS tests, 8 were positive, 3 were negative, and 1 was not tested. In the TPI tests, 5 were positive, 6 negative, and 1 showed nonspecific immobilization. In the agglutination tests, 10 were positive and 2 negative. The serums from the 66 secondary and 33 latent syphilis patients were positive in all of the three tests.

A comparison of the results of quantitative

STS, TPI, and agglutination tests on serum from 15 patients with untreated primary, secondary, or latent syphilis is shown in table 6. Agglutination titers on the 10 positive primary serums ranged from 1:20 to 1:160. Agglutination titers on the 15 secondary serums ranged from 1:20 to 1:2560; and on the 15 latent serums ranged from positive with undiluted serum to positive in the 1:1280 dilution. There was no correlation between the agglutination titers of these serums and the TPI or STS titers.

The result of measuring the relative sensitivity of the TPI test and the agglutination test by another method is shown in table 7. Two-fold dilutions of syphilitic serums were made in saline, and these saline dilutions were then further diluted twofold in normal human serum, with similar dilutions in saline as controls. These second dilutions were tested quantitatively in the TPI and agglutination tests. It is apparent that dilution with human serum did not interfere with the antibody titration, and that the agglutination titer of the syphilitic serum was significantly higher than the TPI titer.

were positive by the agglutination test, and 1 was negative. Of the 15 serums negative by the TPI test, 4 were positive by the agglutination test, and 11 were negative. Of the 26 serums giving nonspecific immobilization in the TPI test, 13 were positive by the agglutination test, and 13 were negative.

Discussion

A method has been described for enhancing the agglutination of *Treponema pallidum* in syphilitic serum by the addition of fresh steer serum. By means of this technique the presence of syphilitic antibody may be demonstrated in a specific test which is completed in only 2 hours. While it is not the object of the present paper to propose the use of this technique as a diagnostic test at present, it has certain obvious advantages over the serologic procedures currently used in the diagnosis of syphilis. Killed spirochetes are used as the

antigen, the antigens may be stored for periods of months in the refrigerator or at $-20^{\circ}\text{C}.$, and the materials could be made available to any serologic laboratory. Studies to date indicate that the agglutination test may have a specificity comparable with that of the TPI test. It also appears to have greater reproducibility than the TPI test, and several times the sensitivity.

The mechanisms involved in the reactions of *T. pallidum* with syphilitic antibody and steer serum are under continued study. It was shown in experiments reported here that the enhancing effect of fresh steer serum in the agglutination test was due to the presence of conglutinin (4). It was found in later experiments not described here that the disappearance of the organisms under the conditions of the TPI test was also caused by conglutinin. It is not yet known whether the disappearance of the spirochetes under the conditions of either the TPI test or the agglutination test is a result of lysis or of

Table 8. Results of TPI and agglutination tests on serum from patients with suspected biological false-positive reagin tests

¹ Nonspecific immobilization in tube containing inactive complement.

unusually strong agglutination. Although results with syphilitic serum absorbed with lipoidal antigen indicate that the agglutination test is probably not a measure of reagin, the identity of the antibody has not been determined. The possible identity of this agglutinating antibody with the TPI antibody (5) or other agglutinating antibodies (1-3) is now being investigated.

Summary

A study has been made of the effects of adding fresh steer serum to mixtures of *T. pallidum* and syphilitic serum. Because of its content of conglutinin, the steer serum caused disappearance rather than immobilization of the spirochetes under the conditions of the TPI test, and greatly accelerated and enhanced the clumping of the organisms in the agglutination test. The agglutination test performed by this method appears to compare favorably both in specificity and sensitivity with the TPI test.

ACKNOWLEDGMENT

Standard serologic tests on the steer serum were obtained through the courtesy of Ad Harris, Venereal Disease Research Laboratory, Communicable Disease Center, Public Health Service, Chamblee, Ga.

Venereal Disease Postgraduate Course

The 21st venereal disease postgraduate course will be held at Chapel Hill, N. C., from September 28 through October 2 under the co-sponsorship of the United States Public Health Service and the North Carolina University Schools of Medicine and Public Health. The course is open to all physicians. Applications for enrollment should be sent to Dr. Harold Magnuson, Director, Venereal Disease Experimental Laboratory, Box 687, Chapel Hill, N. C. The courses previously were held twice annually at the United States Public Health Service Medical Center at Hot Springs, Ark., until the center was closed last June.

American Medicine in a Changing Society

By OVETA CULP HOBBY

IRONICALLY, every advance of man seems to bring its own problems—the Greeks spoke of it as “cost of opportunity.” A changing medical practice and a changing society have presented us with an embarrassing number of what are paradoxically problems of progress. It is the solution of these problems which now concerns us all.

There is little controversy on the objective to be attained—the best medical care possible for people. It is the means to this end which raises the problems. One is the problem of supply. If we are to achieve our objective, the supply of medical care must be adequate and available to all the people. The second is the problem of using these medical resources under a policy which safeguards the traditional principles of our democratic American pattern.

Supply of Medical Care

The problems of supply we are facing include, first, problems relating to ways in which all the fruits of modern medicine can be brought within the reach of all the people. A vast array of new techniques of treatment involving costly equipment, costly medication, costly training, and the services of an army of ancillary personnel are now involved in the

problems of modern medicine. Although the doctor-patient relationship remains dominant, it is no longer a simple relationship. It has been complicated by the introduction of new specialties and factors, as well as by new emphasis on prevention of disease and renewed responsibility for the total health problems of the patient against the background of his situation. Modern medicine is not only complex, it is expensive to supply.

A second problem of supply relates to meeting the cost of research underlying these medical advances and continued progress. A third problem relates to the supply of physicians in the face of the mounting cost of medical education.

Use of Medical Resources

In the use of our medical resources, we must first be careful to work within the democratic principle. Democracy is a doctrine of free will, grounded on the demonstrated ability of man to judge his own individual and common interest on the basis of his common human experience. The freedom of man, therefore, to make his own choices is essential to human dignity, development, and progress. Hence, although man is a social animal and must act with his fellows to achieve the common goals of humanity—freedom and well-being—his right to self-direction must be safeguarded, in such social action, by the establishment of the social controls involved only with his active consent.

The touchstones of democracy are “freedom,” “consent,” and “individual responsibility,” not responsibility vested in an “elite” group with power to make choices and provide for the in-

The Secretary of Health, Education, and Welfare gave this address, here somewhat condensed, before the House of Delegates of the American Medical Association on June 1, 1953, during the 102d annual meeting of the Association in New York City. Her remarks are reproduced in full in the proceedings of the House of Delegates in the Journal of the American Medical Association, June 20, 1953, pp. 740-742.

dividual. In democracy, no one need walk alone, but he does his own walking.

Since we are pledged to the democratic private enterprise system as the system which creates the greatest opportunity for man's achievement of dignity and freedom, any policy which impairs its principles is regressive. The impairment of the principle of free choice and consent in medical care which is inherent in a compulsory program of medical care, therefore, represents a break in the fabric of our democratic system. This break occurs, moreover, in an area in which the value of the elements of "choice" and "consent" is intensified because of the very nature of the service involved. Under such a policy a long turn toward an authoritarian system would be made. The course of this social pathology is dangerously progressive and difficult to reverse.

Economic Considerations

It is clear that the democratic principle to which we are committed is not served by so-called socialized medicine. Such medical practice, moreover, not only violates the democratic principle of free choice and consent but is unsound from an economic point of view—the second principle involved in the use of our medical resources.

Democracy not only protects man's rights to free choice, it is the most economical form of social-political organization man has yet devised. For when the government provides a service, the cost of a round-trip ticket for the dollar from the taxpayer to the government back to the taxpayer must be paid. Hence, the interposition of the government between the doctor and the patient is expensive, and the total resources for medical care, research, and education are, at the last, reduced by the amount of this cost. This is the point which seems never to be fully recognized by those of socialist persuasion.

Equal Opportunity

A third principle which must govern the use of our medical resources is equal opportunity for medical care—the heart of our overall objective. Although in the short run it might appear that socialized medicine may achieve

this end, in the long run its involved and costly administration, its deadly effects on free inquiry and research, and its impairment of democratic rights to free choice ultimately defeat our long-view purposes of continuing medical progress and maintenance of the high standards of medical care which the American medical profession has achieved for this country under a private voluntary system. "Equality" of medical opportunity becomes a hollow victory under these conditions.

Socialized medicine is not a satisfactory solution of our problem. What are the alternatives? As a nation we cannot afford to fail to make available the best medical care possible to all our people. We must find ways to resolve the problems we set forth earlier.

Physicians' Responsibilities

This Administration is looking, first, to the physicians of the country for leadership in meeting this challenge, and we look with confidence.

The history of medicine is a record of devoted service to humanity. The American medical profession has long proved its devotion to these ideals. Its accomplishments constitute a proud record in medical history. The demands of today are only the continuing challenge in this long history of constant adaptation to a changing society, but never have these problems been more onerous and critical than today. I can put these issues no more clearly or forcefully than they were expressed by your president, Dr. Louis H. Bauer (1):

"I am afraid that too many physicians are indulging in wishful thinking that the clock can be turned back and that we can again practice medicine as it was practiced 25 years ago, without involvement in all these socioeconomic problems. It is idleness to believe that. These problems are upon us; our whole way of life has been altered, and, whether we like it or not, we cannot close our eyes to it. If we fail to participate and lead in the solution of these problems, the solution will be taken out of our hands, and that solution will not be a happy one. No problem can be solved well if those most competent to advise hang back and ignore it.

"So it is up to those of us who are active in the affairs of medicine to educate our colleagues and to stimulate their interest in what may be termed the nonscientific aspects of medicine. Unless we handle these nonscientific matters properly, the scientific aspects will suffer, too."

The Citizen and the Community

Second, this Administration looks to the individual citizen to meet his responsibilities: by making full use of resources made available to him through modern medicine for the preservation of his health; by prudent participation in prepaid plans for medical care; and by assumption of common responsibilities for the advancement of the health of our Nation.

Again, we have faith that the individual citizen will meet this challenge. His understanding of the meaning of the questions involved, however, should be widened. Under any plan he pays. He should learn more about what his dollar buys under a compulsory program administered by the government and under a private, voluntary system and what his democratic rights mean to him.

Third, this Administration looks to the community, acting both through its private voluntary associations and its governmental bodies, for help in meeting this challenge.

We are all familiar with the tremendous role of private foundations in the advancement of medical science in this country. It has been estimated that in 1951, philanthropic foundations such as Rockefeller Foundation, Ford Foundation, Commonwealth Fund, New York Foundation, Russell Sage Foundation, Guggenheim Foundation, and many others, contributed \$10 million toward the support of medical research; and voluntary health agencies, such as the American Cancer Society, Damon Runyon Medical Foundation, and National Foundation for Infantile Paralysis, contributed another \$10 million (2). The American Medical Association itself is a donor to causes of medical advancement.

Role of Government

Governmental bodies also carry responsibilities in working out plans of medical care which

meet our conditions and achieve our objectives. The role of government, particularly the Federal Government, is a basic question in our problem. This Administration believes that under a democratic system government has an important role to play.

The broad framework of this government responsibility was defined by President Eisenhower in his State of the Union Message last February when he said: "First, the individual citizen must have safeguards against personal disaster inflicted by forces beyond his control; second, the welfare of the people demands effective and economic performance by the government of certain indispensable social services."

The Department of Health, Education, and Welfare has been created to discharge these responsibilities of the Federal Government. These responsibilities may be broadly defined as those functions which serve the health of the Nation without affecting the doctor-patient relationship in medical practice.

Public Health and Research

The first area of concern is public health—prevention of disease; improvement of standards of sanitation in all areas, including food and drugs; and assistance and consultations to local communities in establishing and maintaining health services. The achievements of government at all levels cooperating with voluntary groups in advancing public health in these fields are too well known to recount.

Another appropriate area of government function is research. Although the achievements of private and voluntary organizations and groups in research have been phenomenal, the increasing scope of research, its cost, its basic and indispensable role in modern medicine make it a field in which government support is sought.

Rehabilitation

Another area in which the Congress has assumed an obligation for medical care is in the rehabilitation program—the restoration of the disabled. This is one of the areas in which private and voluntary medical services have worked closely with government agencies with success, and without prejudicing the principle of voluntary and private medical practice in a service administered by a government agency.

This type of service is a development in democratic society for the community care of those who are unable to provide essential services for themselves. This aspect of our problem is increasing and is becoming one of the underlying issues in the present situation. Because of tremendous advances in medicine, people are living longer and the incidence of chronic disease is increasing. The implications of these facts, and the problems they pose, are well understood.

Medical Education

There remains another area where the pressure of need is compelling a review of all possible methods of solution; that is the area of medical education, where the financial crisis is growing. A recent estimate, based on data accumulated by the Association of American Medical Colleges, shows that medical schools need approximately \$20 million a year to meet current inadequacies. The medical profession has begun to contribute substantial sums (nearly \$1 million to date) to the National Fund for Medical Education, organized to meet this emergency. In May, the fund reported that in addition to this money, corporate gifts amounting to \$570,882 had been received with an additional \$300,000 in sight. At best, only 10 percent of the amount needed is now available.

There must be a renewed drive for voluntary support of medical education and increased support by local governments, for these

problems of medical education cannot go unanswered.

The importance of government responsibilities in these areas is considered of such moment by this Administration that a position for a Special Assistant for Health and Medical Affairs has been set up in the Department of Health, Education, and Welfare.

A Partnership

In closing, let me quote again from Dr. Bauer (1): "We can solve our difficulties if all contribute by sound thinking, by looking forward, not back, and by constant striving toward an ideal that we shall never reach, because we shall steadily increase that ideal."

We already have patterns of cooperation and joint action set by years of close partnership between government, the people, and the medical profession. We can see the results of this partnership in every phase of our national health. We need only to push forward together to achieve a better health care for the people of the United States.

We have the resources. We have the will. We shall surely find the way.

State and Territorial Health Officers' Conference

The 1953 annual conference of the Surgeon General of the Public Health Service and Chief of the Children's Bureau with State and Territorial health officers, State mental health authorities, and representatives of State hospital survey and construction agencies will be held from November 4 through November 7. Open sessions will be held in the auditorium of the Health, Education, and Welfare Building, Washington, D. C., November 5 and 7, beginning at 9:30 a. m. The remainder of the conference will be devoted to executive sessions and committee meetings.

THE CHILD

Educational Films

Educational films on child life are used as a group device for stimulating discussion of family relationships, child development, and the principles of mental health. Dr. Esther E. Prevey reports in the May 1953 issue of *The Child* that such films have been popular in the family life education program of the Kansas City, Mo., public schools.

About 100 groups of parents meet regularly there with parent-education leaders. When parents analyze the fictional family problems they see on the screen, they can talk freely without revealing some of their own problems. To get the maximum help from a selected movie, skillful leadership is needed to encourage and channel the informal group discussion.

Group leaders in Kansas City are guided by a memorandum on the use of films when they direct group discussion. For planning future meetings, they also record helpful information on a film evaluation sheet.

Dr. Prevey mentions two film lists on sale by the Superintendent of Documents, Government Printing Office, Washington 25, D. C. These are: "Mental Health Motion Pictures" (National Institute of Mental Health, National Institutes of Health, Public Health Service, U. S. Department of Health, Education, and Welfare; 124 pp.; 30 cents); and "Motion Pictures on Child Life" (Children's Bureau, U. S. Department of Health, Education, and Welfare; 61 pp.; 40 cents).

Social Casework in Camp

Mrs. Adelaide Z. Palumbo suggests that the trend is apparent that workers in health, education, social work, and camping are teaming up in children's camps. Those who

have worked together in privately owned camps and in organizational camps—the group workers, caseworkers, nurses, psychiatrists, psychologists, and education and recreation specialists—have found that camping is an untapped natural resource for dealing with the "whole child" and his family relationships.

Camp staffs do not yet include social workers, either group workers or caseworkers, although a camp gives service to the child much as does a child guidance clinic, a casework agency, or a neighborhood center. But caseworkers have already had some experience in placing children in camps because family agencies, children's agencies, and health agencies have been sending children to camp for years. Opportunities are present, too, for social workers to work in some camps as counselors, supervisors of counselors, and camp-intake and followup workers.

The children's camp lies within the competence of social workers and offers additional practical experience to work with children, which would be difficult to gain elsewhere. Significant trends in this direction are evident from developments such as these: A recognized school of social work has offered its first course in camping; a vacation association has created the first fellowship for advanced study in social agency camping. Social workers who are planning to work with families and children in casework, group work, or psychiatric agencies would do well to investigate the opportunities for experience offered by those camps which are authorized to give accredited field experience to social work students.

The Child is issued 10 times a year by the Children's Bureau, U. S. Department of Health, Education, and Welfare. \$1.25 a year (\$1.50 foreign mailing), 15 cents a copy, from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C.

Sex Differences in the Trend of Mortality From Certain Chronic Diseases

By GENE KAUFMAN and THEODORE D. WOOLSEY

Differences in the trends of mortality among men and women for cardiovascular-renal diseases, ulcer of the stomach or duodenum, diabetes mellitus, and hernia and intestinal obstruction are examined. A similarity between the pattern of trends for the various age-sex groups in ulcer death rates and in cardiovascular-renal death rates is noted, and the implications of this similarity are discussed.

IN ANALYZING the trend of mortality from the major cardiovascular-renal diseases during the period 1920 to 1947, Moriyama and Woolsey (1) found pronounced differences in the trends for men and women. There was a marked contrast in the direction of the trends for white men and women between ages 35 and 65. Death rates for the major cardiovascular-renal diseases increased considerably among white men in these ages, while the corresponding rates for women were declining.

Various hypotheses have been suggested to

explain this phenomenon. Some of these are: differential effects of changing dietary habits upon the two sexes; differential effects of worry and personal tensions; differential effects of exercise or lack of exercise; changing patterns of urban and rural residence; and differing effects on the aging generation of men and women, which when young passed through the stress of World War I and the influenza pandemic of 1918-19.

While the explanation cannot be finally determined without a great deal of careful investigation, some light may be thrown on the subject by looking for other causes of death which exhibit a disparity in trend between the two sexes similar to that found for the cardiovascular-renal diseases. For this reason, death rates by age and sex for ulcer of the stomach or duodenum, diabetes mellitus, and hernia and intestinal obstruction are presented here for the two 6-year periods, 1921-26 and 1942-47.

The selection of 2 of these 3 causes of death for investigation was made because of the association which is known to exist between death rates for these diseases and 2 factors which may have something to do with the observed trends for cardiovascular-renal mortality. If one factor, tension and worry, played an

Formerly associated with the Division of Public Health Methods, Public Health Service, as a biostatistician in 1951-52, Mr. Kaufman is now with the Office of the Comptroller of the Army, Department of the Army, Washington, D. C., as a statistician and program progress analyst.

Mr. Woolsey, a biostatistician in the morbidity and health statistics branch of the Division of Public Health Methods since 1947, specializes in survey methods for the measurement of illness in the general population. He has participated in studies of mortality for the Division of Public Health Methods and in the past for the National Office of Vital Statistics, Public Health Service.

important part in the trends seen in mortality from chronic diseases of the heart, arteries, and kidneys, a similar pattern with respect to sex differentials might reasonably be expected to show up in the mortality for ulcers. On the other hand, diabetes death rates are known to be related to overweight. Consequently, finding trends of diabetes mortality which exhibited a disparity between the sexes like that seen for the cardiovascular-renal diseases would slightly strengthen the argument for overweight as an explanation of the latter. It was recognized, however, that diabetes was not an ideal selection from this standpoint. The introduction of insulin, which began to affect diabetes mortality in the middle of the 1920's, and, also, certain procedures in the assignment of primary cause of death may have modified the influence of changing proportions of overweight persons on the diabetes death rates.

Death rates for hernia and intestinal obstruction are probably not entirely independent of either of the two factors: tension and worry; and overweight (2). However, there is good reason to believe that their influence on mortality from this cause is very much less than on the two other causes of death. Hence, hernia and intestinal obstruction was chosen as a control for the other two, although "control" is not used here in the strict experimental sense.

Description of Method

The rates shown are for white men and women, ages 25-84, in the Death Registration States of the United States. (A time-series of death rates for the "registration States" refers to statistics which in a particular year are based on all States in the registration area in that year.)

The average number of deaths for each of the 4 causes of death in 3-year periods from 1921-23 through 1945-47 was first computed. This was done separately for each age and sex group shown in the table. Death rates were then computed on the basis of the estimated population for the middle year of each 3-year period. Because the trends for the entire 27-year span were observed to be essentially linear, it was concluded that a comparison of rates in two 6-year periods at the beginning and end of the inter-

val would serve adequately for studying the changes between 1921 and 1947.

The death rates specific for age and sex in the two 3-year periods 1921-23 and 1924-26 were therefore combined to obtain an estimated rate for the 6-year period, 1921-26. In a like manner, estimated rates for the period 1942-47 were computed. The age-specific rates for men and women in these two periods were then compared by means of ratios, the rate for the later period having been divided by the corresponding rate for the earlier one.

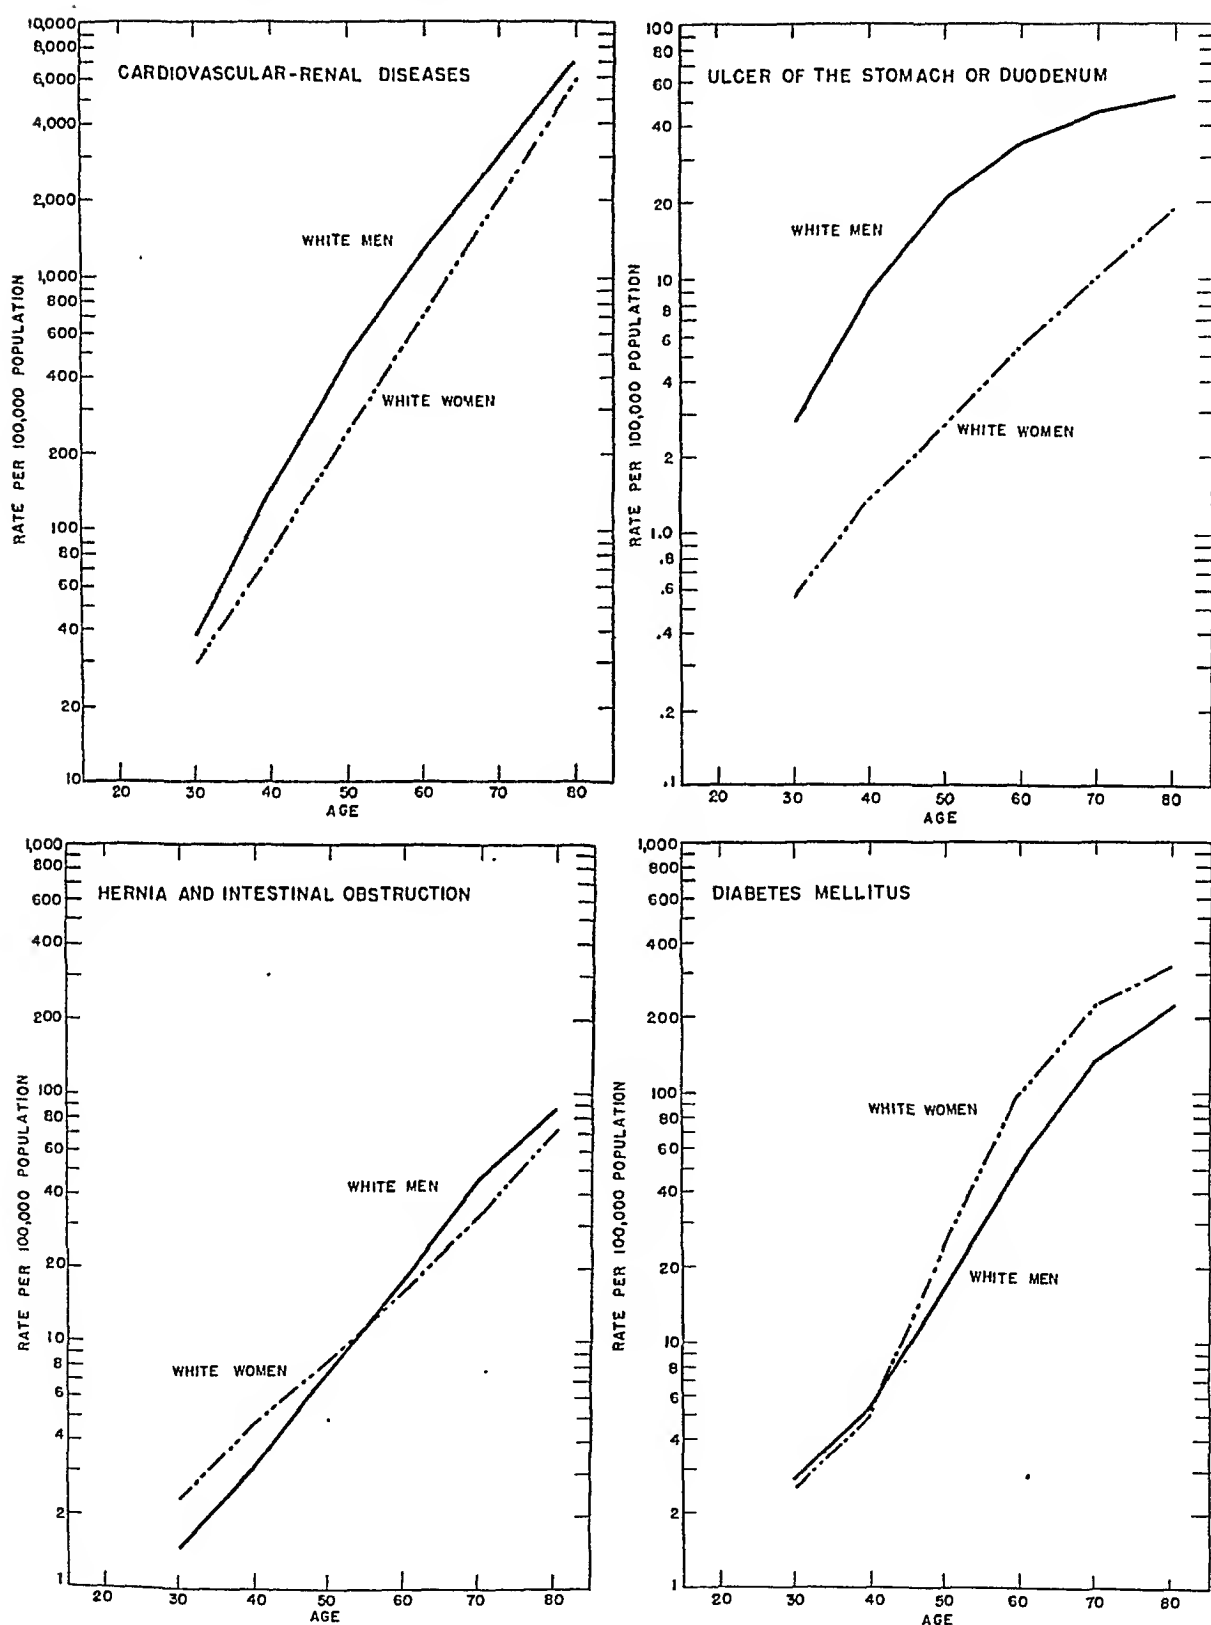

The study was restricted to the 27 years beginning with 1921 because the relative incompleteness of the death registration area prior to that time raises difficult questions concerning comparability of population groups. The death registration area did not actually cover the entire United States until 1933. However, by 1920 there were 34 States and the District of Columbia in the area which then contained 83.2 percent of the white population of the country. For a discussion of the effect of changes in the death registration area on trends of mortality for the cardiovascular-renal diseases, see reference 3.

Discussion

There are two disturbing influences that could alter the trends of mortality in the 27-year span, but neither one is believed to be capable of causing any serious distortion of the trends used in this study. One factor is the effect of changes in the number of States included in the death registration area. The other is the effect of periodic revisions of the International List of Causes of Death, which classifies mortality by cause. Increasing specificity in diagnosis and the improvement of medical knowledge of the nature of various diseases and their relationship to one another have made revision of the International List necessary.

However, the characteristics of the white population of the States in the death registration area from 1921 to 1933 differed only slightly from those of the entire country. Furthermore, the causes and groups of causes selected for examination were chosen because they were

Figure 1. Age-specific death rates for 4 diseases, 1942-47.

not seriously affected by the 1929 and 1938 revisions of the International List.

A more important consideration is the fact that the major emphasis here is on the comparison of trends for men and women. There is no reason to suppose that either of the above-mentioned factors would influence the trend for one sex in any way more or less than it would influence the trend for the other.

Age-specific death rates among white men and women for the major cardiovascular-renal diseases, ulcer of the stomach or duodenum, dia-

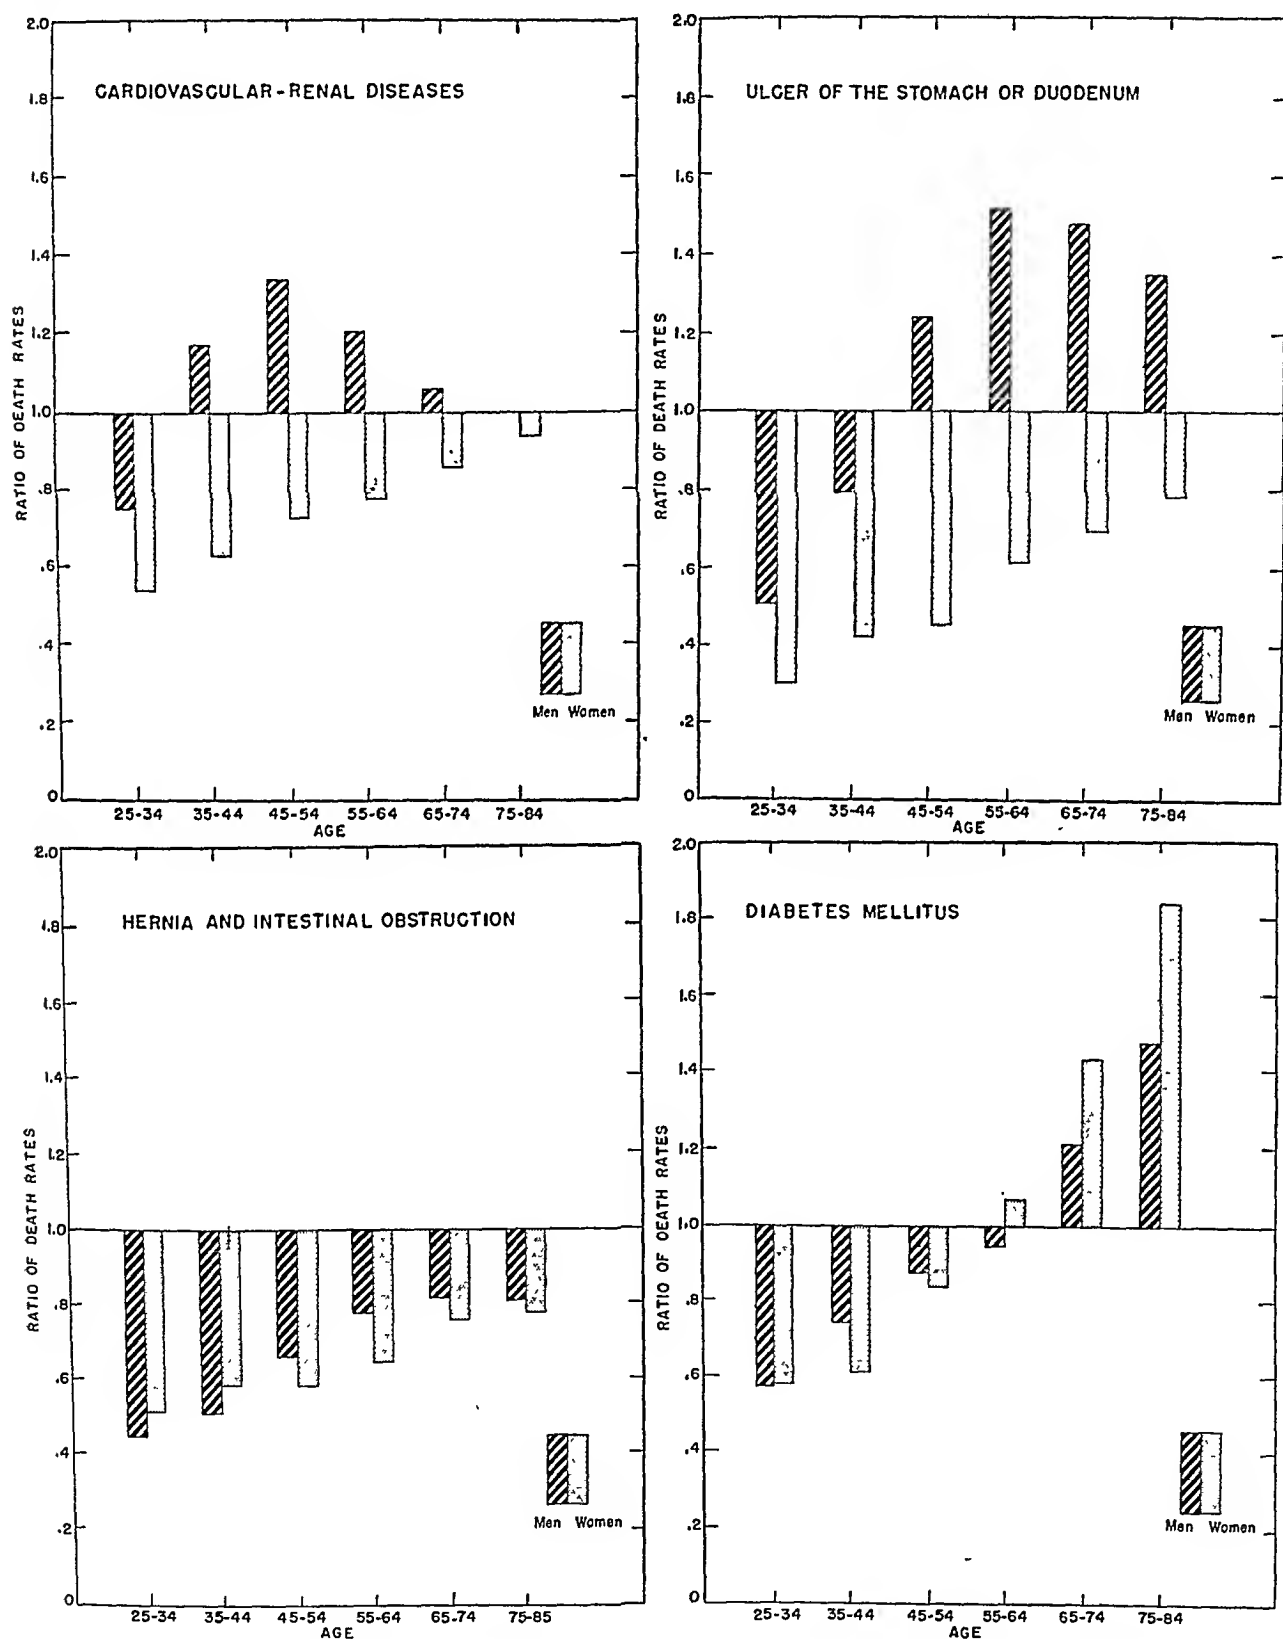

betes mellitus, and hernia and intestinal obstruction are shown in the table for the two 6-year periods, 1921-26 and 1942-47. The rates for the later period are also shown in figure 1 in which all four diseases are plotted on the same logarithmic scale to facilitate the comparison of relative differences between the sexes at the various ages. For each age and sex group, ratios of the 1942-47 rates to the corresponding 1921-26 rates are presented in the table and in figure 2. The same ratios are grouped by age in figure 3 so that the change in mortality for

Age-specific death rates per 100,000 population for 4 diseases among whites, by sex, for 1921-26 and 1942-47, and the ratio of the rates: United States Death Registration States

¹ Rates and ratios in parentheses are based on populations that do not include Armed Forces overseas.

Figure 2. Ratio of age-specific death rates in 1942-47 to corresponding 1921-26 rates, by disease.

the four disease groups among white men and women of a given age may be compared more easily.

It can be seen in figure 1 that the greatest relative excess in the male rate over the female rate for the cardiovascular-renal mortality occurs at ages 45-54. For ulcer of the stomach or duodenum, this maximum discrepancy occurs in the same age group. The largest relative discrepancy between the sexes for diabetes mellitus occurs after age 55, with women exhibiting the higher rate. It is apparent that the relative sex difference in mortality is very much greater for ulcer of stomach or duodenum than it is for the other three disease categories.

Age-Sex Patterns of Change

In both the cardiovascular-renal diseases and ulcers, the mortality among white women has been declining in the period studied, but the rate of this decline is consistently less with each succeeding age group from 25 to 85. Among men, there is a downward trend in mortality for both of these disease groups in the 25-34 age group. This downward trend changes to an upward trend in middle age, but beyond a certain age the rate of the increase declines. The greatest increase in the male cardiovascular-renal mortality is observed at ages 45-54, while at ages 75-84 there has been little or no change. In the ulcer mortality, however, the peak rate of increase among men is seen to be at ages 55-64. At later ages it decreases significantly, but the ratio of mortality in 1942-47 to that in 1921-26 does not drop back to 1.0 in the 75-84 age group as it does in the cardiovascular-renal group.

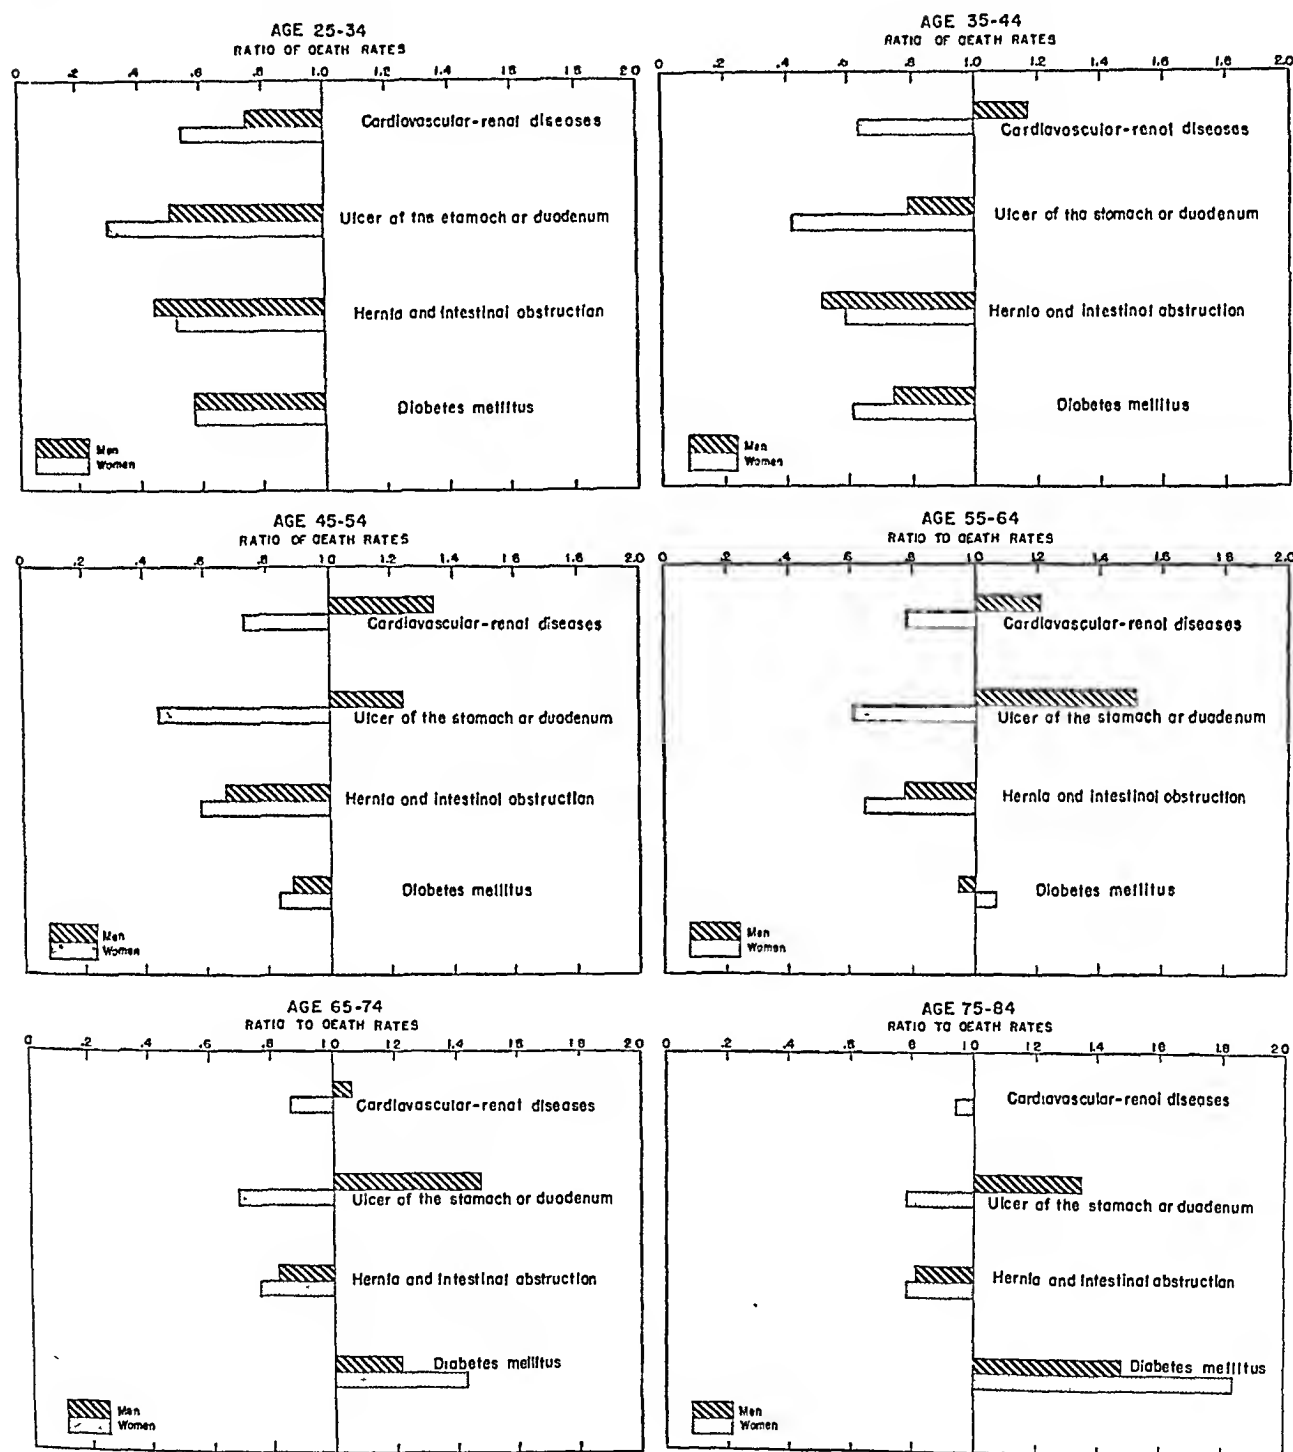

The pattern of change by sex and age for hernia and intestinal obstruction is quite different from that for the cardiovascular-renal diseases and ulcers. The pattern for diabetes is again different. Hernia mortality for both sexes has declined in all age groups although to a lesser extent in the older ages. With the exception of the first two age groups, 25-34 and 35-44, female mortality has decreased more rapidly than male mortality, but the difference between the trends for the sexes is very much less marked than in the cardiovascular-renal

diseases and in ulcers of the stomach or duodenum.

Diabetes mortality dropped about 40 percent in the 25-34-year age group during the 27-year span, but the picture with each succeeding age group appears less favorable. The mortality among the aged from diabetes is known to be heavily weighted with deaths of persons succumbing with the disease rather than from it. Although there has been an increase in the number of deaths from diabetes, the death rate of diabetic patients has definitely improved. As Dublin and Lotka point out (4), the probability of diabetes being diagnosed has greatly increased, and consequently, it is not at all surprising that the number of death certificates on which diabetes is mentioned has increased. Hence, the apparently unfavorable trend beyond age 65 is probably the result of the increasing life expectancy of diabetic patients. It is the sex differential in trend, rather than the trend itself with which this study is concerned, and here it is seen that after age 55 the trend for women is less favorable than that for men. Below age 55 the trend for men has been less favorable in 2 of the 3 age groups.

The pattern of change by age and sex for hernia and intestinal obstruction or for diabetes is not at all similar to that for the major cardiovascular-renal diseases. However, the similarity in the pattern of change for cardiovascular-renal and ulcer of the stomach or duodenum death rates is striking. This resemblance may be purely coincidental in the sense that the factors responsible for the changes in cardiovascular-renal mortality may be quite different from those producing the changes in the ulcer death rates. It is also possible that the same factors are responsible in both trends but that these factors have nothing to do with the etiology of the diseases. For example, there might have been an increasing opportunity for men to obtain a diagnosis of an ulcer or a heart condition—an opportunity which, for some reason or other, women were not getting. The evidence presented here by no means constitutes proof, nor does it even create a strong likelihood that tension and worry are the cause of the relatively unfavorable mortality among men of the later working ages.

Figure 3. Ratio of age-specific death rates in 1942-47 to corresponding 1921-26 rates, by age group.

However, this evidence should be taken into account in choosing the hypothesis for further investigation. More specifically, the similarity between the trends for cardiovascular-renal and ulcer mortality makes the investigation of the relationship between psychosomatic factors and

the cardiovascular-renal diseases a particularly promising possibility.

It must be emphasized once more that the differences between the rate of change in mortality for the sexes is of concern here rather than the magnitude of the rate of change itself.

Owing to the procedure employed until 1949 in assigning the primary cause of death for statistical purposes (5), the death rate did not always measure accurately the trend in the inherent risk of death from a given disease. This was particularly true of diabetes, since the former procedure for the selection of primary cause resulted in the assignment of many deaths to diabetes in cases in which this disease was listed by the physician as merely a contributory cause. An investigation conducted by the Metropolitan Life Insurance Co. in 1935 indicated that "53 percent of 3,519 deceased diabetic policyholders, for whom the facts were known, died from degenerative conditions of the heart, kidney, or arteries, 13 percent from infectious diseases, 4 percent from cancer, and 4 percent from tuberculosis" (4, p. 339). Yet, if diabetes had been mentioned on the death certificate in these cases, the death would have been classified as a "diabetes" death in the official death statistics for at least half of the cases. However, there is no obvious reason for supposing that

this factor would tend to operate differentially on the mortality for either sex.

Closing of Two PHS Hospitals

Two Public Health Service hospitals—one at Cleveland and one at Fort Stanton, N. Mex.—are in the process of closing.

Closure of the Fort Stanton facility, a tuberculosis sanatorium, will be completed when its patients are transferred to other Service hospitals. Curtailment of operating funds for Service hospitals was the reason for the decision.

At Cleveland, the 190-bed general hospital has discontinued admissions. When its present patients, mostly veterans, have been discharged or transferred, an outpatient clinic will be established in downtown Cleveland. Emergency hospitalization for Service beneficiaries will be provided by contract arrangement at local hospitals.

Come-up Time Method Of Milk Pasteurization

By DENZEL J. HANKINSON, Ph.D., R. B. READ, M.S., WARREN LITSKY, Ph.D., and ROBERT R. BROWN, M.S.

CONVENTIONAL milk pasteurization treatment recognized by State and Federal statutes includes the vat method (143° F. for 30 minutes) and the high-temperature, short-time method (161° F. for 15 seconds). The high-temperature, short-time method has gained in popularity in the larger milk plants because of reduced space requirements and ease of application of regeneration (heat exchange from hot to cold milk). One disadvantage of the high-temperature, short-time method is the difficulty in accurately measuring and establishing the holding time at the short interval of a few seconds.

One solution to this difficulty is the elimination of the holding time, and hence the holding tube, by increasing the temperature to the point where only the "come-up" time will insure adequate pasteurization. This is the time required to heat milk to a given temperature. Studies at Cornell University in 1941 (1) indicated that this approach offers some possibilities.

In order that an adequate margin of safety may be established, standards should be based on a shorter come-up time than is possible with commercial milk heating equipment. Furthermore, since it is believed that any new definition of pasteurization should be based upon studies

with pathogenic bacteria, equipment that would permit such studies was designed. Basically, the equipment consists of a stainless steel pressure tank and small-bore stainless steel tubing. The tube is heated by high amperage, low voltage alternating current connected to the tubing at three or more points. This arrangement is illustrated schematically in the chart. Dimensions and operational data are as follows:

Capacity of pressure tank	5.0 gal.
Flow rate	5.75 to 11.5 gal. per hr.
Flow velocity	10 to 20 ft. per sec.
Reynolds number	3,500 to 7,000.
Air pressure required	30 to 120 lb. per sq. in.
Length of heating tube	2 to 10 ft.
Diameter of heating tube	0.065" i.d. × 0.125" o. d.
"Come-up" time, total	0.1 sec. to 1.0 sec.
Estimated time from final heating to collecting vessel (at 20 ft. per sec.)	0.025 sec.
Temperature rise, max.	170° F.
Rate of heating	170° to 1,700° F. per sec.
Operating voltage (a. c.)	0 to 15.
Operating amperage	0 to 1,200.

Results of preliminary studies have indicated that phosphatase is destroyed and that there is a 100-percent kill of a 24-hour culture of *Escherichia coli* within the range of 176° to 185° F. at heating rates varying from 170° to 1,700° F. per second. Flavor observations on milk heated to 200° F. indicated quality at least comparable to high-temperature, short-time pasteurization. Studies on pathogenic bacteria will be initiated after satisfactory operating ranges are established with the phosphatase test and with heat-resistant test organisms.

This method of heating in continuous flow, by which rates of flow and temperatures can be readily controlled, should permit the accumulation of reliable data on thermal destruction of enzymes, heat-resistant test organisms and, more important, on pathogenic bacteria, all of which are necessary before acceptance can be obtained for any process of importance to public health. Other applications could be found for the equipment in studying heating effects on fruit juices, wines, and other fluids in which controlled heating is required.

If these studies indicate that come-up time pasteurization is effective at temperatures less

Dr. Hankinson is with the department of dairy industry, Mr. Read and Dr. Litsky, the department of bacteriology and public health, and Mr. Brown, the department of electrical engineering, of the University of Massachusetts, Amherst, Mass. This investigation was supported by a research grant from the National Institutes of Health of the Public Health Service and is a contribution of the Massachusetts Agricultural Experiment Station.

than 200° F., it should be possible to apply the process with existing high-temperature, short-time equipment. The necessary alterations would be (a) elimination of the holding tube and (b) raising of the "cut-out" temperature for the flow diversion valve. The health inspector would no longer need to check both temper-

ature and holding time, only the pasteurizing temperature.

Applications for Cancer Research Grants

Applications for new grants-in-aid for cancer research will be accepted before October 1, 1953, by the Committee on Growth, National Research Council. The grants will be effective July 1, 1954.

The Committee on Growth is acting for the American Cancer Society, which upon recommendation of the committee awarded approximately 250 grants totaling more than \$1.7 million during the past year. In addition to clinical investigations on cancer, the scope of the research program includes fundamental studies in the fields of cellular physiology, morphogenesis, genetics, virology, biochemistry, metabolism, nutrition, cytochemistry, physics, radiobiology, chemotherapy, endocrinology, and environmental cancer.

Investigators now receiving grants will be individually notified regarding renewal applications. Application forms and additional information may be obtained from the Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

Public Health Today— The Nation's Best Investment

By LEONARD A. SCHEELE, M.D.

PUBLIC HEALTH is a human institution. Unlike eternal truths, it is not "the same" yesterday, today, and tomorrow. Instead, it is dynamic, subject to change, and constantly changing. Even as we meet here this morning, "today" is rushing to become time past; and "tomorrow," to become time present.

Public health cannot afford to be the same today as it was yesterday, or as it will be tomorrow. For while we are thinking about public health today—while the clock ticks away the next half hour:

Forty people in the United States will die from cardiovascular diseases.

In the same 30 minutes, another 12 will die from cancer.

Five more will die in accidents.

That is the toll which these causes alone exact every half hour today—and will exact every half hour tomorrow.

If these facts are at once dramatic and sobering, consider this: For more than 1,750,000 Americans, this half hour will be the same as the last, and the next, and all the rest this year. These are the people of all ages whose diseases, injuries, or impairments disable throughout time. To many of them, death is not as difficult to contemplate as the ticking of the clock into the hours and days of invalidism ahead.

The Surgeon General's presentation was part of a symposium on "public health yesterday, today, and tomorrow" at the 22d annual meeting of the Southern Branch, American Public Health Association, in Atlanta, Ga., April 23, 1953.

Spur to Action

A consciousness of needless death and suffering has always given public health workers a sense of urgency in their planning and daily operations. We have, however, lost—or are losing—some of that strong drive, for our very successes have eased the spur in many of our programs.

Plainly, it is more difficult to feel the urgency of diphtheria immunizations in school health work today than it was years ago when the first active immunizing agents were developed and diphtheria outbreaks were an ever present spur. In malaria control, it is more difficult to retain a strong motivation for tracking down a dozen or so indigenous cases in a wide, sparsely populated area than it was barely 5 years ago to conduct a vigorous DDT program in the many communities with high malaria rates.

Some of you may recall the plea of William James that society develop a "moral equivalent for war," in order that man may exercise his aggressive drives without destroying himself. To paraphrase that proposal: In our public health work, we need a psychological equivalent for epidemics. Without some such spur, we run the risk of ignoring the need for vigorous action against the major health problems of our times, and of sinking into desultory performance of our customary activities. The public, observing the apparent ease with which old threats to life and health are controlled and being insufficiently aware of present threats, can be excused for questioning the necessity of its substantial investment in public health.

The whole array of protective measures against communicable diseases is so woven into the average American's life that he takes the benefits for granted. Epidemiological investigations, sanitation, licensing of biological products, and quarantine, for example, operate day by day with very few citizens, relatively speaking, being aware of their influence. Even case-finding, immunization, and treatment activities reach directly only a small proportion of the total population. To many people, public health work seems rather dull routine.

In the perspective of time past, time present, and time future, however, public health measures have had spectacular results. The average length of life in this country has increased 5 years since 1940; 8 years since 1930; and 19 years since 1900. A population gaining in longevity and general well-being finds it easy to overlook the indispensability of public health work, even in fields nearly conquered. In the light of the Nation's health gains, however, public health is our best investment.

Economics of Public Health

According to the most recent estimates, there are between 35,000 and 40,000 public health workers in official health agencies in the United States. Of these, 28,000 are professional and technical personnel providing some type of full-time local health service to 70 percent of the total population in the continental United States, roughly 106,000,000 people.

Although the Nation's investment in public health and related services has increased since World War II, expenditures for the promotion of health and the prevention of disease and disability still comprise a small proportion of the total health and medical care expenditures. Public health budgets also are small in comparison with budgets for hospital and medical care.

The American public is spending about \$14 billion annually for all types of civilian health and medical services. Expenditures for the conservative services—prevention of disease, promotion of health, and medical rehabilitation of the disabled—amount to only 6 percent of the total. The total expenditure for the conservative services, from all sources, is thus well under \$1 billion annually.

The implications are clear. Unless the health conservation services are sustained, unless health research is sustained, hope must be abandoned for any substantial reduction of the enormous burden that hospital and medical care imposes on all people—often when it is too late to bring the individual health or even life.

Public health and related services are relatively inexpensive. Public health progress has been achieved, in fact, through consistent search for, and development of, relatively low-cost techniques.

It is not so much the low cost of public health as it is its enormous returns in human and economic values that makes it a profitable investment. The results, however, do not show up as rapidly or as discretely as do the profits from investment in new products, for public health is dealing primarily with the human organism in its varied environments. It may take a decade or more to evaluate the economic gain from some important forward move in public health. Hence, in assessing public health today, we have to look back to yesterday.

Costs and Savings

Indeed, it seems but yesterday in these southern States when the most conservative estimate placed the economic cost of malaria alone at half a billion dollars a year. The intensive DDT program which lifted this burden from the south cost about one tenth of a single year's economic loss. There are few citizens today who do not credit malaria control with its contribution to the great economic advance of the southern States in the past decade. The campaigns against hookworm and pellagra belong to an earlier period, but these public health investments also have played a major part in the economic progress of the south.

Reductions in deaths and disability due to tuberculosis and syphilis are saving untold millions in dollars and in days of productive work. At the same time, improved infant and child health is assuring that a larger proportion of Americans will become productive members of our society.

Control of industrial health hazards, developed from continuing research and applied in

many of the Nation's industrial establishments, protects the majority of workers in the United States from occupational diseases. Prevention of accidents in industry, through safety devices and education, has reduced dramatically the death rates due to industrial injuries. The savings in productivity and compensation costs as a result of health and safety services in industry are incalculable. Some large industries, for example, have reduced the man-days lost from nonoccupational illness by 50 percent, with a concurrent decrease in sickness and accident payments of 35 percent.

Vocational rehabilitation programs, which include medical and hospital services when required, are returning more than 60,000 Americans to productive occupations annually, at a total cost of less than \$33 million. Before rehabilitation, the total annual earning of these people is about \$16 million. The first year after rehabilitation, their total income is \$116 million. A recent study shows that the cost of rehabilitating 376 families in West Virginia was less than the \$225,000 they had been receiving annually in public assistance. No longer dependent on public funds, these families are now earning about \$500,000 a year.

There are gaps in our current public health methods, it is true, but these gaps point up the tremendous importance of research. Since World War II, the United States has launched the most intensive medical research offensive in the history of our country or any other. This campaign is acquiring powerful momentum. The flow of findings predicted 5 years ago is now appearing. If continuity of medical research is maintained, substantial progress toward effective means of dealing with the chief killers and cripples of today is assured for tomorrow.

The potential gains to the Nation in better health for our people and in economic savings are stupendous. The investment required to maintain the current research effort and to extend it into unexplored fields, like the investment in public health and related services, is small when placed beside the Nation's expenditures for hospital and medical care, and still smaller when placed beside the costs of illness

and needless death in terms of lost productivity and dependency.

The Job Today

The investment in public health, though small in comparison with other expenditures, is substantial. Are we making the investment yield the best possible returns?

Many responsible health officials believe that we cannot answer that question without much more careful study of our programs and practices than is the general custom. Public health is a part of, and is influenced by, the great social and economic forces which operate in any dynamic civilization. It functions best when its leaders are alert to the changes occurring and when they take the initiative to keep public health practice responsible to the changing needs of the people.

We have a responsibility to see to it that the jobs given us to do are done with maximal efficiency; without needless duplication and expense, but with full attention to health needs. That is a large order in this day of rising prices and personnel shortages.

The major shifts in the causes of death and disability are familiar to all of us. The chronic diseases are becoming more and more significant as the population ages and the toll of acute infectious diseases is reduced.

Long-term disability due to chronic diseases is a heavy burden to the sufferer and a tremendous economic cost to the Nation. The chronicity and disabling effects of tuberculosis and syphilis have given public health workers striking evidence of this fact. Notable success against these two infectious diseases has been achieved during the past 10 or 15 years. However, tuberculosis deaths still cost the United States annually 1 million years of future working-life and \$350 million for hospital and medical care. Paresis in male patients alone costs an estimated annual loss of \$112 million in income.

In assessing our needs for personnel and funds, we must scrutinize our practices in every program and be prepared to concentrate our forces upon the most effective techniques. We must abandon techniques that careful evaluation studies reveal to be nonproductive. Many

public health practices which we have conceived as universally essential and universally applicable may have very limited value in dealing with the health problems of today as our social and physical environment changes. The basic skills of public health workers are, however, adaptable; what is wanted is the most effective utilization of those skills combined with the most effective utilization of the new instruments and agents flowing from scientific research and development.

Our past successes in public health have led many of us to believe that "more of the same" will accomplish results and that the public will continue to increase support on that basis. A popular song gives us the answer: "T'aint necessarily so!" Our task today, therefore, is to learn quickly how to spend better the funds for which we are responsible, whether they are derived from Federal, State, or local taxes, or from public subscription and private donations.

Chronic Disease Prevention

At the present time, a major strategic goal of public health is to strike at the roots of chronic disease by preventive methods. Preventive knowledge and methods in the field of chronic disease are such, however, that the practicing physician and the hospital have the major share in achieving this strategic goal of public health.

A basic problem in public health today, therefore, is to devise means whereby the skills of the private physician, the public health staff, and the hospital may become increasingly united for the prevention of disease and its disabling effects, and the promotion of health.

Our public health experience in syphilis control has given us valuable guidelines as to what is needed to bring about such effective utilization of resources. Medical science has provided both efficient laboratory tests to detect infection and remarkably effective therapies that can be administered by the general practitioner in his office, as well as by the outpatient department. Public health has developed effective case-finding and followup procedures, as well as other supporting services valuable to the physician. As a result, we can expect a continued decline in syphilis if the united efforts of public health

department staffs and private physicians are not relaxed.

This victory was not won overnight. It has taken more than a quarter of a century of co-operative research, of trial and error, of patience and persistence to achieve the present hopeful position in syphilis control. Even now we cannot say that we have all the answers, that there will be no further scientific or administrative advances in syphilis control. But we have developed methods which other programs may profitably emulate or adapt.

We have made a beginning in tuberculosis control, also; but case finding and therapy in this field, useful as they have been, have not attained a demonstrated efficiency comparable with that in syphilis control. Other chronic disease control programs, such as heart disease and cancer, are still in experimental stages. Although there are a few promising developments here and there about the country, effective preventive programs in these fields await new findings in basic and applied research.

The Community and Public Health

Responsible citizens in every walk of life have an intellectual interest in medical research and an intellectual concern that its vital mission be accomplished. But it is the public health services in the local community that command the emotional interest and concern of every citizen. The adequacy or inadequacy of local public health services has an immediate impact on each family, each individual.

More than ever before in history, public health today is the product of the local community. Unquestionably, the pioneer movement to stimulate local initiative in the prevention of disease is the most significant contribution of the public health profession to the Nation's welfare. The pattern of local health service has been developed by the profession and sometimes has been offered to communities for adoption with relatively little consideration of the tremendous social changes in this country, and of the shifts in population, in patterns of community life, and in health problems.

During the past 5 years, the United States Congress, after careful study, has not accepted proposals for specific, increased Federal aid to

local health units. This fact should stimulate the public health profession to analyze critically the lag in the development of full-time local health units.

The Congress represents and is responsive to the will of the people in health matters, as in other matters. There has been no lack of congressional interest in public health, and there is no lack today. The factors which operate to retard the development of local health units are many and complex. Let us consider briefly a few of the principal influences.

Since the end of World War II, the Congress has been faced with enormous financial demands upon the Federal Government. Nationwide concern has mounted, and with it has come a demand for increased State and local responsibility and independence in many domestic enterprises, including public health. Parallel with the increase in national and personal income, as well as in prices and taxes, there has been a growth and extension of Federal grants-in-aid to the States. The present system of Federal aid to the States is complex and involves many fundamental questions of governmental functions and fiscal responsibility. It is indeed a major problem in Federal, State, and local administration.

Federal-State Relations

Recognizing the seriousness of the problem and the necessity for rational solutions, the President of the United States has proposed—and legislation has been introduced in Congress—to establish a temporary Commission on Governmental Functions and Fiscal Resources whose major responsibility would be to study and make recommendations to Congress on the entire field of Federal activities in aid to State and local governments. Under the proposed legislation, the commission would be composed of 25 members: 15 to be appointed by the President and 5 each by the Senate and the House of Representatives. The commission would be expected to submit its report and recommendations in March 1954.

In a message to Congress on this subject, President Eisenhower, commenting on the national problem of Federal-State relations, said: "To reallocate certain of these activities between

Federal and State Governments, including their local subdivisions, is in no sense to lessen our concern for the objectives of these programs. On the contrary, these programs can be made more effective instruments serving the security and welfare of our citizens."

This is a statement of policy to which every responsible public health worker will subscribe. We must not wait, however, until the proposed commission has made its recommendations. We must begin now our studies of how our programs can be made more effective. As long ago as 1945, the Public Health Service pointed out that a larger share of the costs of basic health services should be borne by State and local governments. In general, this has occurred; but the major increase in State and local health expenditures has been in the fields of hospital and medical care.

I would urge the physicians, the health officers, and the citizens of our towns, counties, and States to work toward providing more financial support for the worthwhile old and planned new programs. Everyone should understand that the total financial obligations of the Federal Government, the current effort to bring the Federal budget into balance and ultimately to lower taxes, may well make it necessary to reduce Federal grants-in-aid to the States for public health work. Such a reduction should not be reflected in lessened service. The elimination of unnecessary and low priority projects, increased State and local appropriations, and greater voluntary support should more than balance any loss of Federal grants.

The continuing role of the Public Health Service will be to help the States with studies and demonstrations, or pilot programs, and technical leadership. We should all remember this basic principle of our democracy: Initiative and major action are the province and responsibility of the citizens and the States, free from any Federal paternalism that might destroy initiative in the public interest. We can expect that the Commission on Governmental Functions and Fiscal Resources will provide official agencies with an agreed, proper base for future Federal-State relations and Federal financial grants in the health field.

State and Local Responsibility

There should be substantially increased State and local activities in public health services—prevention of disease, environmental health, promotion of family and individual health, and medical rehabilitation of the disabled. This philosophy was expressed by the Hoover Commission when it reported: "The health of the Nation demands maximum employment of present scientific knowledge to control disease, and of research to find new methods for the prevention of disease. . . . The Nation's future can best be protected by using every means to prevent disease, rather than by providing unlimited hospitalization to treat it."

Until more State governments and legislatures and more local communities have adopted this philosophy, until they become zealots in its application, we can expect little progress in the further development of local health services. Public health workers as salesmen must also critically evaluate the product they wish to sell, in terms of the specific health needs and resources of specific communities.

It would be difficult to say, for example, to what extent our public health practices have been influenced by the truly remarkable advances in the prevention and treatment of acute communicable diseases during the past decade. Are our demands for laboratory procedures and public health nursing services in this field realistic? Are we providing services, once valuable, but no longer necessary? Improved technology in food production, processing, and distribution also challenge many of our standard sanitation techniques devised to protect us in earlier days. In the meantime, many serious needs remain unserved. Yet, we frequently base our estimates of costs and personnel required for local health services on the standard techniques that were defined 20 or 30 years ago.

Program Appraisal

The shortage of professional personnel in all categories is still acute. This statement, I realize, is growing a little shopworn. Thousands of speakers have made it from hundreds of platforms since the beginning of World War II. If we are not careful, it can become a dangerous

sedative to lull our awareness that we are doing so little to meet the personnel needs.

Our public health economists are the first to tell us that the available criteria for measuring "shortages" of personnel are far from specific. At best, such measurements afford us only a means for detecting the uneven distribution of health personnel. We have not yet developed sufficient scientific data on the effectiveness of specific techniques or on the functions and the performance of the different categories of professional workers to permit a completely realistic appraisal of our needs.

A few significant studies have been completed in the fields of hospital nursing and dental care. Others are in progress on the utilization of physicians' time in office and hospital practice. These point inevitably to the conclusion that many of our difficulties in staffing could be overcome by more efficient utilization of personnel in "scarce" categories, by increased use of less scarce personnel in related professions, and by increased use of well-trained, nonprofessional personnel.

During the past year, the Public Health Service attempted to develop a study of the amount and kinds of nursing service required to meet the minimum needs of local health departments. We found that studying the needs of a single type of service is not enough. Nor is it enough to study the needs for other types of personnel. We must have broader studies, aimed at determining the types of organization that will be most effective in meeting the health needs of different types of communities. On this basis, staffing requirements can be assessed efficiently.

Many local health organizations as now constituted cannot cope with today's problems—with the chronic diseases and impairments, with the health needs of the aging, with the chemical environment, and similar problems of contemporary society. Newer programs have been initiated to deal with some of these problems, but they do not always fit into the traditional structure of local health organization.

If public health tomorrow is to be a more effective instrument for service to the community, we must be vitally concerned today with appraisal of our current programs and

practices. We must be vitally concerned that the methods we propose are adaptable to the needs of different types of communities. Local health organization is indispensable and it must be strengthened—if tomorrow's health is to eclipse that of today. But public health must learn new ways of organization as well as new operating techniques in order to develop the kind of local health service that will meet tomorrow's needs.

Conclusion

Public health today is a part of public health yesterday and of public health tomorrow. Yet, tomorrow public health workers of all categories will be facing many of the same routine tasks. There will be the usual backlog of work, with additional tasks arriving every hour. There will be the same problems of staffing and recruitment; the same questions, seemingly unanswerable, about how to do today's job without

enough people and money. There will be little time to step back and think.

Somehow we must find time for reflection. Public health today is in a period of transition: a period in which we may see a realignment of the sources of financial support and of the functions of many organizations engaged in public health and related services. Yet, this can be one of the healthiest periods in the history of organized public health services. For if the public health profession responds to the demands of today with full exercise of the scientific method in which we have been trained, rather than with emotional attachment to the tasks of the moment, we can vastly improve our operations; bring the influence of preventive medicine and environmental health to bear upon related services; and extend the tested techniques and skills of public health into many fields still awaiting cultivation. This task is at once the task of public health today—and tomorrow.

Public Health Service Staff Announcements

Elisabeth Boeker, Public Health Service nurse officer, is the first nurse to be sent to Iraq under the Point IV technical aid program. Miss Boeker will work with Iraqi nurses and other health aides to assist in developing public health nursing services in that country. She will advise the Iraqi Ministry of Health on nursing matters. In Basra she will help organize the nursing section of a new local health department and train public health nurses.

Margaret E. Benson has been appointed chief of infectious and tropical disease nursing of the Public Health Service Clinical Center at the National Institutes of Health. Miss Benson has served in various staff nursing and instructional capacities at the Minneapolis General Hospital

and the University of Minnesota School of Nursing. Since 1951 she has been special consultant to the Division of Nursing Resources, Bureau of Medical Services, Public Health Service.

Meral Loewus, a Public Health Service nurse officer, has been assigned to the Technical Cooperation Administration Mission to Iran where she will direct nursing education at the Nemazee Hospital of Nursing in Shiraz. The hospital, scheduled to open next year, is being built by the Iran Foundation, and the mission is helping provide staff members until their Iranian counterparts can take over. Miss Loewus will work with Iranian nurses in setting up the new school of nursing. Until recently, she was associate professor in the department of nursing at Montana State College.

Community

Fly Control Operations

16 mm., sound, black and white, 12 minutes, 1952.

Audience: Sanitarions, entomologists, public health personnel, and students engaged in or interested in community fly control.

Available: Loan—Public Health Service, Communicable Disease Center, 50 7th St. NE., Atlanta 5, Ga. Purchase—United World Films, Inc., 1445 Park Ave., New York 29, N. Y.

A successful fly control project as carried out in a typical town is shown in this film, designed to educate the residents of a community in fly control and to gain their support in the project.

The film presents a basic plan of attack that can be used to control flies in any community—education, sanitation, and chemical control.

These three measures are developed in the film by showing the procedures carried out by visiting State fly control specialists, local public health and municipal officials, and residents. The community is surveyed to estimate the number of flies present. The main fly breeding sites—exposed garbage, animal shelters and waste, industrial waste, and insanitary privies—are located. Residents are shown how they can aid in eliminating some of the fly breeding sites. Help is given city officials in solving the more expensive municipal problems of fly control.

Fly control supervisor carries education program to schools.

Community fly control supervisor advises mayor's committee on major municipal problem (open garbage dump).

Citizens' response to educational program—keeping animal waste in containers in privately owned animal shelters.

Insecticides are used for immediate relief and as a supplementary measure in the difficult problem areas, but basic sanitation is emphasized as a necessary factor in the permanent control of flies.

These measures, the film points out, will control fly problems but will never completely eliminate them. Routine vigilance must be continued indefinitely by making periodic fly counts, by keeping a check on possible breeding sites, and by using insecticides to combat occasional small outbreaks.

Fly problem site (stockyards) treated with residual spray.

Swimming Pool

Sanitation

35 mm. filmstrip, sound, color, 8 minutes, 1952

Audience: Stole training officers, sanitarians, and others interested in desirable swimming pool characteristics and operational procedures.

Available: Loan—Public Health Service, Communicable Disease Center, 50 7th St. NE., Atlanta 5, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

Rapid gravity filters.

Cleaning pool.

This filmstrip shows some of the physical characteristics and the operating procedures basic to swimming pool sanitation.

Planning and construction: details size considerations, ratio of deep to shallow water area, overflow gutters, desirable provisions for recirculation type pools, units of the recirculation system, and several different filter methods.

Operation: includes provisions for operation such as dressing rooms, scheduling of sanitary operations, emergency preparations for breakdowns, and bathhouse maintenance.

Half a Century of International Control Of the Venereal Diseases

By THEODORE J. BAUER, M.D.

IN INTERNATIONAL negotiations to develop acceptable quarantine regulations, with which the international health movement was primarily occupied for many decades, venereal disease was of little importance. It was cholera and plague, smallpox, yellow fever, and typhus which engaged the principal attention of governments in their dealings with one another on health questions. Until after 1910, emphasis in international discussions of syphilis was often placed upon its social rather than its medical aspects, partly, perhaps, because of the poverty of preventive and therapeutic knowledge.

By the time the Health Organization of the League of Nations came into being, however, knowledge of the diagnosis and treatment of this disease had grown enormously. And as broader collaboration in health matters developed among nations, syphilis came to be recognized as a widespread and serious health problem. The Health Organization established an expert committee on syphilis, and from this group stemmed much of the useful work sponsored by the League in studying and standardizing certain venereal disease control procedures and techniques developed in the first decades of the 20th century.

In a somewhat different area, the International Union Against the Venereal Diseases also

began its work in the years just after World War I. At this time, many nations began campaigns and programs against venereal disease, employing varied methods and approaches. The International Union has attempted to foster these programs and to generate support for venereal disease control nationally and internationally.

Both of these organizations, the League and the International Union, participated in a movement to provide venereal disease control services for merchant seamen. The result of this movement was the Brussels Agreement of 1924, a landmark in international venereal disease control and still an effective instrument for providing venereal disease treatment facilities for seamen.

Since World War II, the keystone of international venereal disease control has been the venereal and treponemal disease program of the World Health Organization. The modern concept of international health efforts, that of assisting nations to improve health services and conditions internally, has been given broad application in the venereal disease program, which includes training of personnel, provision of demonstration teams, exchange of scientific knowledge, and mass application of antibiotic therapy in areas of high treponemal disease prevalence.

Antiquity of Syphilis

One of the classic controversies of medical history centers about the origin of syphilis: Whether it was brought to Europe from the New World at the close of the 15th century or existed there in antiquity. Whichever theory is correct, syphilis apparently was present in Europe

Dr. Bauer is the medical officer in charge of the Communicable Disease Center, Atlanta, Ga., and former chief of the Division of Venereal Disease, Public Health Service. He is a member of the Expert Committee on Venereal Infections and Treponematoses of the World Health Organization.

at least by 1495. An epidemic of the disease in malignant form is usually said to have swept the continent at about that time, striking first in France, Spain, and Italy, and spreading quickly to Germany and Switzerland. Holland, Greece, and England knew it in 1496; Hungary and Russia in 1499. It is said to have ranged to the Far East early in the next century (1, 2).

Some writers believe that instead of a virulent syphilis racing across Europe after 1493, one or several infectious diseases, perhaps in combination with syphilis, were confused with and designated as the latter, thus giving rise to the "epidemic of syphilis" theory so often cited (3).

If the epidemic of about 1500 was indeed syphilis, the disease began to change within the following 50 years and has not since assumed the same violence and rapid fatality. Probably because it did not compare in virulence with such diseases as cholera and plague, syphilis did not figure prominently in later discussions of quarantine regulations designed to prevent the spread of disease from country to country (4-6).

Collaboration in Health

Nevertheless, in the 19th century particularly, debates and negotiations among nations on the subject of quarantine indirectly affected the development of international venereal disease control measures.

The 19th century was a time of progress in shipping and transport and consequently of growing trade and travel. Nations were drawn into closer and more diverse relationships, creating common problems calling for cooperative action. Yet, machinery through which national spokesmen could debate or act together on technical matters was lacking. In this situation, nations turned to the international conference. "When a problem became particularly acute," says Boudreau (7) of this period, "a government took upon itself the responsibility of calling an international conference . . ." The French Government called the First International Sanitary Conference in 1851, primarily to thrash out problems of quarantine and to seek unity in the prevention of cholera and plague. This conference represented the beginning of cooperation among nations in the field of health

and sanitation. In the next half-century, a score of conferences dealt with typhus, smallpox, and yellow fever as well as cholera and plague, and in 1907 the Office Internationale d'Hygiène Publique was established as a permanent international health office, concerned chiefly with enforcement and revision of the international sanitary conventions (6, 8, 9).

Once established, the principle of collaboration in health matters never died. Eventually, it was applied to the problem of venereal disease.

Approaches to VD Control

Before 1910, many countries confined their syphilis control efforts to regulation or repression of prostitution. Internationally, likewise, when venereal disease was discussed it was often closely identified with broad social issues rather than with health per se.

Yet, the importance of syphilis as an international health problem began to emerge at least toward the end of the 19th century. In 1899, an International Conference on the Prophylaxis of Syphilis was held at Brussels; in 1902, a second conference on the same subject, also held at Brussels, recommended among other things free treatment for all persons infected with venereal disease and distribution of leaflets emphasizing its dangers to persons entering the armed forces. Various groups, for example, the League of Red Cross Societies, the International Labour Office, and the International Union Against the Venereal Diseases, later held meetings which approached venereal disease as either a medical or a social problem or both.

The latter organization, the International Union, merits a special word as a voluntary organization with a continuous record of service. After World War I, many countries began campaigns against venereal disease; approaches and methods varied, however, and results were uneven. Speaking in 1928 of the disparity in modes of attacking the venereal disease problem, Professor A. Bayet of Brussels, first chairman of the International Union Against the Venereal Diseases, said (10): ". . . some countries . . . concentrate on the social effects . . .; others concentrate on individual treatment, aiming above all at the cure of the patient himself; others place their trust in laws and regulations, and others, without having any definite

programme, do what they can here and there without any unified plan."

This diversity in methods of attacking the venereal disease problem led to the foundation of the International Union Against the Venereal Diseases. At a series of conferences organized in 1921 by the League of Red Cross Societies to discuss venereal disease, the need became apparent for establishing a forum where varying viewpoints could be aired and a measure of uniformity sought in national approaches to venereal disease control. Founded in 1923, the International Union has sought since its earliest days to aid countries represented in its membership in developing sound principles of venereal disease control. This organization has also performed useful service in publicizing venereal disease control and in stimulating public support of control efforts (10).

League of Nations

With creation, following World War I, of the Health Organization of the League of Nations—with greater resources and broader functions than the Office Internationale d'Hygiène Publique—potentially effective machinery was established for a sustained global attack on health problems. The Health Organization began operating in a world where international health involved many questions other than quarantine. Among the problems faced by the young organization, for example, was that of standardizing many of the new "biologicals" and the procedures which advances in the medical sciences had produced (8).

Responsive to these new factors, the Health Organization of the League of Nations undertook early in its history to establish international standards for serums, biological products, and serologic reactions. Standardization was needed not only in performing serum tests for syphilis but also in interpreting and recording test results. The Health Organization of the League of Nations arranged conferences of experts in 1921, 1922, and 1923. The latter meeting and subsequent gatherings in 1928 and 1930 were working laboratory conferences, which evolved many valuable rules of serologic testing.

Standardization of antivenereal disease drugs was also part of the Health Organization's program, which embraced both arsenicals and penicillin. Provisional standards for the latter were established in 1944 (8).

Syphilis therapy also was studied. By the time the Health Organization came into being, arsenical treatment had gained wide acceptance among physicians. Various schemes and dosages were employed, however, and as Vonderlehr and Heller (11) have put it, "Almost every doctor who attained a scientific reputation in the treatment of the venereal diseases had his own plan for use of the arsphenamines." Beginning in 1928, through the agency of a Commission of Experts on Syphilis and Cognate Subjects, the Health Organization undertook an extensive inquiry into methods of treating syphilis with the arsenicals. More than 25,000 case records from clinics in Germany, Denmark, France, the United Kingdom, and the United States were analyzed. Results of the study, re-

ported in 1934, engendered widespread interest among health administrators and syphilologists.

The Brussels Agreement

The most specific accomplishment in international venereal disease control before World War II was the Brussels Agreement of 1924. The moving forces behind this convention, designed to provide venereal disease treatment facilities for merchant seamen, were the Health Organization of the League of Nations, the Office Internationale d'Hygiène Publique, the International Labour Office, and the International Union Against the Venereal Diseases. The agreement calls for maintenance of venereal disease treatment services for seamen and watermen in the ports of signatories. This occupational group, seamen and watermen, moving from port to port and particularly subject to exposure to venereal infection, had long been looked upon as an important factor in VD epidemiology.

The Brussels Agreement was an attempt to deal with this problem in a straightforward manner. Signed on December 1, 1924, by 1938 the convention was ratified or adhered to by 56 nations, dependencies, special ports, or island groups. In practical terms, its purposes have been effectuated somewhat more broadly than the number of its adherents would indicate. For example, the United States is not a signatory; but, after passage of the Venereal Disease Control Act of 1938, foreign seamen have been permitted to obtain treatment for venereal disease in clinics organized under the act, and the clinics themselves have been included in the International Treatment Center List provided for by the agreement (12, 13).

VD Control Before World War II

In a narrow sense, the record of international venereal disease control before World War II shows but few enterprises of substantial importance. Probably most valuable were the Brussels Agreement and the trailblazing done by the League of Nations in cooperative studies of syphilis serology and treatment. Beyond these specifics, however, lies the maturing of the whole concept of cooperative attacks on disease. In its modern form this concept involves the building up of an effective program

of health and disease control in each nation of the world. This approach was first demonstrated by the Rockefeller Foundation, which has worked effectively since 1913 toward developing cooperative action in the health field (14, 15).

To implement international cooperation as it applies to venereal infections, the early years of the 20th century produced the diagnostic and therapeutic processes which make possible the medical control of syphilis—demonstration of *Treponema pallidum*, development of the serologic test, use of the darkfield procedure in diagnosing early syphilis, and the enormous contribution of Ehrlich, salvarsan. There are, of course, a host of other factors—social, political, ethical, medical—which influence the international health movement. But those are far beyond the scope of this paper.

Principles for WHO Program

In the recommendations of the Interim Commission of the World Health Organization to the First World Health Assembly, held in Geneva in 1948, venereal disease control was among the programs assigned top priority. In selecting priorities, three principles guided the Commission (9): The worldwide or regional importance of the problem; the possibility of effective international action; the increased urgency of the problem as a result of war.

While there were no statistical guides by which the extent of the global venereal disease problem could be precisely assessed, data were adequate to establish the high prevalence of this group of infections and the aggravation of the problem as a result of the war. There was ample cause to believe that an international venereal disease program could be successful. Newly introduced methods of treatment, particularly penicillin, had removed many of the drawbacks of older forms of therapy; furthermore, the Interim Commission considered that, on the basis of past international experience in the field, renewed action against venereal disease was feasible. Thus, venereal disease control fitted well into the WHO plan of concentrating its initial efforts on "impact" programs. The First World Health Assembly accepted the priorities recommended by the Interim Commission, and authorized establish-

ment of expert committees in the priority areas (8).

WHO's venereal disease control program has been broadened since 1948 to encompass non-venereal treponematoses (yaws, pinta, bejel). At first, the Expert Committee on Venereal Disease, mindful of its terms of reference, had recommended against bringing bejel and related spirochetoses within the scope of WHO's venereal disease control program. Although the committee recognized that these diseases merited the attention of WHO, it felt that because of the "predominantly nonvenereal nature of these conditions" (16) they should constitute a separate activity of the world organization. Later, however, noting the "demonstrated uniform response of various treponematoses" to penicillin (13), and other technical and administrative considerations, the committee gave its approval to the broader program. The Second World Health Assembly (1949) decided that an expert group on treponematoses should be established under the program projected for 1950. Following the favorable attitude of the Expert Committee on Venereal Disease as to combining treponematoses (in addition to syphilis) with the venereal disease control program, the Executive Board of WHO approved the merger of the two expert groups. The enlarged committee held its first meeting under its broadened terms of reference in August 1952.

Criteria for Broadened Program

The content and accomplishments of WHO's venereal disease and treponematoses control program are described in WHO publications and elsewhere, and no attempt will be made here to analyze them in detail. However, because this program stands at the center of today's international attack upon venereal infections, a few of the chief premises on which the program functions will be summarized:

1. WHO's approach to venereal disease control is one of public health. At its first session, the expert committee (17), while recognizing the "vast social implications of venereal disease," suggested that WHO concentrate on the public health and medical aspects at least "until definite plans on . . . social aspects . . . now under consideration by the United Nations

and other international organizations become available."

2. One of the objectives of WHO's venereal disease control program is to help member countries establish and develop permanent control structures within national health administrations. Emphasis is placed on underdeveloped areas of high venereal disease prevalence.

3. Assistance in training venereal disease control personnel is supplied through fellowships and demonstration services and through support of training institutions in areas where facilities are limited. Demonstration teams and other phases of WHO's training program in venereal disease control are conceived as beginning points from which not only national venereal disease control programs but also broad public health programs can ultimately develop (13).

4. Efficient serologic testing for treponematoses is a prime requisite of an effective venereal disease control program. WHO's interest in serology is epitomized by the establishment of a Subcommittee on Serology and Laboratory Aspects (of the Expert Committee on Venereal Infections and Treponematoses) which is actively pursuing the ideal of worldwide standardization of serologic procedure, technique, and reporting of results in serum tests for treponematoses. Both the parent group and the subcommittee have emphasized the advantages of the cardiolipin and lecithin antigens in serologic testing. Through the cooperation of the Expert Committee on Biological Standardization, international reference preparations of these antigen components have been deposited with the Standards Department of the State Serum Institute, Copenhagen, and a standard description of them has been included in the International Pharmacopoeia. Several countries in Europe have begun to produce these substances, and there are plans for similar steps in Southeast Asia and in the Americas (in addition to the United States, where cardiolipin and lecithin antigens were first developed) (17, 18).

5. Penicillin therapy is in general use in WHO-sponsored programs of treponemal disease control. While the problem of penicillin production and distribution was separated from the venereal disease program by the First World Health Assembly, the expert committee has

watched the subject with great interest and concern. In fact, at its second session in 1948 the committee observed that in its opinion (16), "... the limited availability of penicillin [was] the outstanding restricting factor in venereal disease control in the world today." The economic commissions of the United Nations and WHO have worked together to stimulate production of penicillin, and the antibiotic is becoming somewhat more accessible for worldwide use. A Section on Antibiotics has been created within the WHO Secretariat, reflecting the importance with which this subject is viewed within the organization (13).

6. One of the great needs of the world in venereal disease control is the exchange of scientific information on venereal disease among professional workers. To aid in meeting this need, WHO has prepared a number of technical documents from data collected from many parts of the world. Another manner of meeting this need is through international meetings of experts and other workers. For example, in 1950, an International Symposium on Syphilis was held in Helsinki, Finland, through the cooperation with WHO of the Finnish and French health administrations. In March 1952, the First International Symposium on Yaws was held in Bangkok, in an effort to draw together the experience and thinking of professional workers on a disease which exists widely in Africa, Asia, certain of the Pacific Islands, and parts of the Americas.

7. The maritime aspects of venereal disease control have been studied by WHO from its earliest days. At its first session in 1948, the expert committee considered the view expressed by the Economic and Social Council of the United Nations that diplomatic conventions in technical fields should be replaced by health regulations adopted by the World Health Assembly. In 1949, at its third session the committee, having noted that delays are unavoidable in developing such regulations, pointed out the importance of the Brussels Agreement as the "sole practical instrument for venereal disease control between countries" (13, 17).

A particular segment of the maritime venereal disease problem has been attacked by the International Anti-Venereal Disease Commis-

sion of the Rhine. After discussion between WHO and the governments of Belgium, the Netherlands, France, Germany, and Switzerland, the Commission was established in 1951 to coordinate venereal disease services of these five nations for the benefit of the Rhine River boatmen and their families—a floating population of some 45,000 persons—and to establish diagnostic and treatment facilities in the principal ports of the river. An extension of the Commission's work is the Port Demonstration Project, established in Rotterdam to study venereal disease control among seafarers.

8. As units of a global structure, regional health organizations have been established to serve the needs of particular areas. The regional system of WHO was completed in 1951. There are today six regional offices covering Africa, the Americas, the Eastern Mediterranean, Europe, Southeast Asia, and the Western Pacific. The Regional Office of the Americas has been established in the Pan American Sanitary Bureau in Washington.

PASB and WHO Projects

Actually, the PASB has a far longer history in international health than WHO. The first health agency to function over a wide area for many governments, it antedates the Office Internationale d'Hygiène Publique by several years, having been formally organized by the Pan American Sanitary Conference in 1902. It functions today both as WHO's regional office and independently as the operating agency of the Pan American Sanitary Organization (8, 9).

A number of WHO-sponsored or -aided venereal disease control projects have been and are being conducted in the Americas. A yaws-eradication program in Haiti, for example, is being conducted under an agreement between PASB (as WHO's regional office), United Nations International Children's Emergency Fund, and the Haitian Government. Numerous South American countries have some kind of WHO-aided venereal disease control projects in progress, for example, demonstration and training projects in Ecuador and Paraguay, a training center in Venezuela, and laboratory training programs in Guatemala and Brazil.

(Right) Director of Health at Sarajevo and leader of the Yugoslav-WHO-UNICEF antiepidemic syphilis campaign in Bosnia, examines boy's mouth for syphilitic lesions.

A number of other cooperative venereal disease control operations have been conducted in Mexico, Central America, and South America, through bilateral planning between the United States and other individual governments. And during World War II, the Inter-American Cooperative Health Program was initiated among the American Republics not only to provide medical and public health services for war workers but also to supplement and extend long-term disease control programs. Functioning through the Institute of Inter-American Affairs and the governments concerned, this program included VD control operations. At present, the Institute is co-operating with the Mexican Government and the Pan American Sanitary Bureau in a VD control program along the Mexico-United States border (19).

The PHS and the International Program

The Public Health Service entered the international venereal disease control picture through the League of Nations clinical studies

of syphilotherapy. Requested to participate in these studies, the Public Health Service undertook to assemble 10,000 case records from syphilis clinics in the United States, to analyze them, and to forward the records to the League for further analysis and comparison with data from other countries. Incidentally, at the time the League studies were begun, the Service decided to utilize the same sources of data in the United States for a more intensive investigation of the results of treatment of syphilis in this country. The participants in this inquiry—leading syphilis clinics—were the first members of the Cooperative Clinical Group, which developed some of the most comprehensive statistical and clinical studies of syphilis treatment on record.

The United States venereal disease control program, through its successful application of public health techniques to the venereal disease problem, has influenced the structure and content of WHO's antivenereal disease activities. In 1949, a seven-member Syphilis Study Commission of WHO toured venereal disease control

installations in this country (a) to evaluate methods in use in the United States and the importance of these methods in national and international programs, and (b) to study control methods, particularly penicillin treatment in syphilis. The Commission reported the organization and methods in the United States to be a helpful guide in planning future programs in other parts of the world, subject, of course, to adaptations to meet local conditions and problems.

Standardized laboratory procedures in the United States program and methods employed in compiling and analyzing statistical data were approved. Certain features of training and utilization of personnel were also viewed with favor, for example, special training in venereal disease control for medical officers assigned to this field, and performance by specially trained nurses, health educators, and investigators of a major part of epidemiological, educational, and technical work (20).

Undoubtedly, the experience in the United States with penicillin has hastened acceptance of this form of therapy in the international program. The WHO Syphilis Study Commission thought that the drug used in a control program is less important in diminishing the amount of venereal disease than the ready availability of treatment facilities plus an active case-finding program. Nevertheless, it recognized that the rapidity and nontoxicity of penicillin therapy makes this antibiotic of great value in syphilis control.

Results of WHO's Program

One of the most significant undertakings of WHO in treponemal disease control, in terms of permanent progress, is the training phase of the program. Personnel are being indoctrinated in essentials of public health practice which will serve both specialized treponemal disease campaigns and generalized health programs. For the private physician in contact with epidemiological and treatment demonstrations, there is opportunity to learn some of the attitudes and substance of preventive medicine—particularly important in areas where physicians receive little of these in their medical training.

Some valuable lessons in the methodology of mass attacks on disease are emerging. Clark (21) has pointed out the contribution to epidemiology made by the endemic syphilis program in Bosnia, Yugoslavia. Reynolds and Guthe (22) have summarized conclusions on case finding and treatment reached in WHO's early programs of mass penicillin therapy. These and other experiences indicate that in mass treatment programs a very high percentage of the population involved must be reached for examination if results are to be satisfactory. Experience in Haiti has given some excellent leads as to how this high level of coverage may be obtained. Where reliance is placed on voluntary clinic attendance, even when bolstered by a public appeal campaign, less than half the population will be reached. When, in addition, mobile clinics are used in strategic areas, the percentage rises to 70. Ninety-percent coverage in Haiti was achieved only when a house-to-house survey was employed.

Towering above all other results, real or potential, of international treponemal and venereal disease control is the prospect that the massive prevalence of these diseases may be cut down and possibly eradicated in large areas. Both in terms of humanitarian objectives and of economic improvement of the areas involved, this prospect has very broad ramifications indeed.

It has been pointed out that treatment alone has never eradicated a disease on a global scale; neither has vaccination nor environmental sanitation. But history abounds with instances of disease controlled by public health methods, and WHO's experience with mass treatment of venereal and treponemal disease encourages the belief that control and possibly eradication of these infections can be achieved.

This experience shows that infectiousness in treponematoses can be significantly reduced by mass use of penicillin in aluminum monostearate. In the Bosnia program, cases of secondary syphilis were found at the first control examination to be about 10 percent of the number found at the beginning of the campaign. At later examinations, this number was further reduced. While results are less spectacular in

other campaigns, significant reductions in infections cases have occurred in programs in Haiti, Indonesia, Thailand, and Iraq. Up to January 1953, well over 9,000,000 persons had been examined and over 3,000,000 treated for treponemal disease in intensive campaigns sponsored by WHO and often substantially aided by UNICEF (22).

A single mass treatment campaign in an area is not sufficient to master permanently the venereal or treponemal disease problem in that area. Successful public health programs are usually protracted affairs. In treponemal and venereal disease, there must be a continuing effort to decrease the number of infectious cases, and resurveys are necessary to prevent recrudescence. Many factors—extent of the disease, completeness of case finding, opportunities for reintroduction—must be considered before the question of how many mass surveys can be answered for an area. Infectious cases must be brought down to the point where the local case-finding and treatment operation is adequate to deal with remaining pockets of infectious cases. Clearly, the more mature and complete the local public health organization, the earlier it can assume full responsibility for the local disease situation.

This fact helps to illuminate the wisdom of WHO's approach to venereal and treponemal disease control: to aid, to the extent of its resources, in the immediate diminution of disease in areas of greatest need, and at the same time to assist in building permanent public health structures especially through training of native personnel. This kind of attack, well supported and continuous, makes bright the hope that effective worldwide control of venereal and treponemal disease can be accomplished.

U. S. Birth Statistics, January–April 1953

In April 1953 there were an estimated 292,000 live births. This is the first time in about a year that births were not higher than the corresponding monthly figure of the previous year. The birth rate on an annual basis for this April—22.5 per 1,000 population—was also somewhat lower than a year ago. In 1952, however, April births had been close to the all-time record for this month.

For the first 4 months of 1953, the total number of births remained high. During this period, births occurred at an annual rate of 24.4 per 1,000 population, and totaled an estimated 1,262,000. This is 23,000, or 2 percent, more than was estimated for the same period last year. These estimates allow for under-registration of births.

Estimated total live births and birth rates for the United States, 1940–50

NOTE: Data based on births adjusted for under-registration.

Since the end of World War II, more children have been born every year than in any wartime or prewar year. From an estimated 2,858,000 births in 1945 the total soared to 3,817,000 in 1947. After dropping to a slightly lower level for the next 3 years, the birth total reached a new high in 1951, and broke the rec-

ord again in 1952 with an estimated 3,889,000 live births.

Based on registered births alone, 58,000 more couples had a first child in 1951 than in 1950, according to preliminary estimates. This 5-percent increase in first-born children was largely a sequel to the marriage upswing that began in June 1950, at the start of the Korean War. Births of second-born children increased

Estimated total live births and registered live births, and birth rates in the United States, 1940–52, and January–April 1952 and 1953

¹ All rates on an annual basis. For 1940 and 1950, rates based on enumerated population residing in the United States as of April 1; for 1941–46, based on estimated midyear population including Armed Forces overseas; for 1947–49, 1951, and 1952, based on estimated midyear population excluding Armed Forces overseas; for January–March 1952 and 1953 based on quarterly estimates of the population excluding Armed Forces overseas.

² Preliminary estimates.

moderately (2 percent over 1950), while increases in third and fourth births were more substantial—9 percent and 13 percent, respectively—continuing a steady rise that has been going on since the end of World War II.

Prepared by the National Office of Vital Statistics, Public Health Service.

Incidence of Reactions To Antirabies Horse Serum

By THOMAS S. HOSTY, Ph.D.,
and FRANK R. HUNTER

THE REAWAKENING of interest in the development of hyperimmune rabies serum has made available a new approach to the prevention of rabies in man. Several groups of workers are now, or have been, exploring the use of serum as an adjunct to the classic vaccination procedure or possibly even as an outright replacement of vaccination (1-3).

During a recent outbreak of rabies in Birmingham, Ala., two children died from rabies, despite prompt and intensive vaccination with 14 Semple treatments. The incubation time was 17 days in one child and 19 in the other. Such short incubation periods allow very little time for the development of immunity. The Alabama State Department of Public Health laboratory in Birmingham, therefore, made available, first, hyperimmune antirabies rabbit serum and, later, a hyperimmune antirabies horse serum concentrate, to supplement vaccination.

This report deals with the use of the horse serum concentrate, which was provided by Lederle Laboratories with the request that the incidence of serum sickness following its use be assessed. The horse serum concentrate was used only on patients having face, neck, arm, and hand bites, the patients having been skin-tested before administration of the serum. Serum was not used if the bite occurred longer than 72 hours prior to the time serum could be given. The dosage was 0.25 ml. per pound of body weight given intramuscularly, followed in 24 hours with at least a 7-course treatment of Semple vaccine unless a shorter course was indicated by the condition of the biting dog.

Dr. Hosty is director of laboratories of the Alabama Department of Public Health. Mr. Hunter is director of the department's branch laboratory in Birmingham.

Serum Reactions

Reactions to antirabies horse serum concentrate in 32 patients are presented in the table. Eight of the patients had attacks of serum sickness of varying intensity. Only three of these reactions were severe and two were moderate. The latter two reactions were on a mother and daughter. If the three slight reactions are discounted, the reaction rate is 15.6 percent, a figure which compares favorably with reported reaction rates following the use of rabbit serum and is far less than reported rates following the use of sheep serum (3). If this reaction rate is maintained with more extensive experience, the use of antirabies horse serum in the presence of a negative skin test would not be contraindicated.

Ten of the patients were bitten by dogs proved rabid. The presence or absence of virus in the submaxillary glands of the dogs, however, was not determined except for patient 32. In this instance, rabies virus was demonstrated in an LD₅₀ titer of 10⁻⁴. Four additional patients were bitten by dogs in which rabies was doubtful. In one instance the biting dog was not found, and in two instances the animals were killed and the brains found negative for Negri bodies. In the latter two cases, no animal inoculation was done. In one other instance, Negri bodies were found by one laboratory but not by another. Animal inoculation in this case, however, was negative. Of the patients bitten by dogs proved rabid, 7 had face bites; 2, finger bites; and 1, leg bites. Of those bitten by doubtful rabid animals, 2 had face bites; and 2, finger bites.

Discussion

Experimentally the use of antirabies serum has a good foundation (2, 3). One adverse report which has appeared is not based on recent experimental evidence (4). It is not possible, of course, to draw a definite conclusion as to the value of serum on the basis of this limited study. It is safe to say, however, that there are no serious contraindications to its use and that it may indeed have done some good.

In view of the fact that 7 patients with face or neck bites and 2 with finger bites from rabid

Data on 32 patients treated with hyperimmune rabies serum of horse extraction

Patient	Age (years)	Weight (pounds)	Location of bite	Nature of bite	Animal rabid	Number of days Sample vaccine given	Serum dosage (ml.)	Reaction
1-----	8	87	Face-----	Severe-----	No-----	9	20	None.

24-----	8	60	Face-----	Severe-----	No-----	2	15	None.
25-----	28	160	Neck-----	Mild-----	Yes-----	14	40	Mild. ¹
26-----	8	60	Thumb-----	Moderate-----	Yes-----	14	15	Mild. ²
27-----	4	32	Lip-----	Mild-----	No-----	7	8	Mild. ³
28-----	31	128	Fingers-----	Moderate-----	Doubtful-----	14	32	Moderate. ⁴
29-----	8 (mo.)	20	Face-----	Mild-----	Doubtful-----	14	5	Moderate. ⁵
30-----	2	31	Forehead, eyelid, and leg.	Moderate-----	Yes-----	14	8	Severe. ⁶
31-----	26	134	Two fingers-----	Mild-----	Doubtful-----	14	33	Severe. ⁷
32 ⁸ -----	6	40	Nose-----	Mild-----	Yes-----	14	10	Severe. ⁹

¹ Slight urticaria 10 days later.² Slight rash at site of injection 11 days later.³ Slight redness and itching around injection area 8 days after, lasting 2 days.⁴ Rash 4 hours after injection. Rash reappeared after 5 days, lasting 5 days.⁵ Urticarial rash 5 days after injection, lasting 5 days.⁶ Fever, nausea, and vomiting fifth through ninth day.⁷ Severe urticarial reaction with swelling, fever, pain, nausea. Cleared in 11 days.⁸ Virus isolated from submaxillary gland of dog, LD₅₀ titer of 10⁻⁴.⁹ Rash and swelling after third day. Cleared in 5 days.

dogs were treated with a low potency vaccine, as measured by the Habel test, and that Sellers (5) has shown that the risk of infection is 72 times greater in face bites than in leg bites and 5 times greater in hand bites than in leg bites, it may be assumed that these patients were at great risk. Certainly patient 32 was exposed to infection because of the large amount of virus present in the submaxillary gland. None of the patients have to date developed rabies.

At present, it is premature to rely on serum treatment alone. If its use, however, permits a reduction in the number of vaccine treatments

from the usual 14 to perhaps 7 or less, this would in itself be a distinct advantage, since a shorter course of vaccine treatment should reduce the risk of postvaccination paralysis. Serum is also advantageous in cases in which the biting dog cannot be found immediately. Its use would allow time for a thorough search for the dog before vaccine treatment is initiated. When vaccine treatment is indicated only on the theory that any animal bite, no matter how trivial, can produce rabies, judicious use of serum might permit elimination of vaccination and at the same time offer the patient mental

relief. Finally, in the presence of severe face and hand bites, simultaneous use of serum and vaccine should materially reduce the danger of infection, if, in fact, the serum alone were not efficacious. The prolonging of the incubation period through the use of serum gives more time for active immunity to develop from the vaccine.

Conclusion

Further experience is needed to determine the value of antirabies serum. At present, however, it should be considered as another worthwhile tool in the prevention of rabies and should be used wherever indicated.

ACKNOWLEDGMENT

The authors wish to acknowledge the assistance of Dr. George A. Denison, county health officer, Birmingham,

Ala., in making this study, and of Dr. M. Schaeffer, director of the virus laboratory, Communicable Disease Center, Public Health Service, and Dr. Hilary Koprowski, Lederle Laboratories, in preparing the report.

Municipal Sewage Treatment Plant Construction

A total of 515 communities in the United States were awarded contracts in 1952 involving an expenditure of \$137 million for construction of municipal sewage treatment plants, according to a recent report released in May by the Public Health Service. Of these contracts, 314 were for new plants costing \$78,419,556; and 201, costing \$58,789,133, were for additions, enlargements, or replacements of existing plants.

The report compares the 1952 rate for this type of construction with the annual rate of from \$450 million to \$500 million estimated to be required over a 10-year period to bring the pollution caused by municipal wastes under reasonable control. The 1952 total of \$137 million is less than that for any year since 1948. It also falls short of the long-term average of \$141 million for the period 1915-50.

The report is available in the Division of Water Pollution Control, Bureau of State Services, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C.

During the first quarter of 1953, \$31 million was invested by 119 municipalities for sewage treatment projects. Of these, 61 contracts were for construction of new sewage treatment plants; 48 were for enlargement or improvement of existing plants, and 10 were for construction of interceptor sewers.

OCCUPATIONAL HEALTH

Radiation Exposures

In the July (and final issue) of *Occupational Health*, Duncan A. Haladay summarizes the potential health problem from exposure to radiation. For many of the biological effects of radiation, there is a threshold dose below which no permanent damage will occur, he writes. For certain effects, such as the production of mutations, shortening of the life span, and possibly carcinogenesis, there is no lower threshold.

"Animal experiments and such data as we have on humans indicate that moderate radiation doses will increase the normal radiation rate," Mr. Haladay points out. For this particular effect, all radiation exposures are additive. "Calculations of radiation doses from various sources, such as the industrial and medical use of radiation, indicate that it is possible for an average person to be exposed to biologically significant amounts of radiation."

Mr. Haladay, an engineer with the Occupational Health Field Station of the Public Health Service at Salt Lake City, advises "all health departments to obtain data on the location of sources of radiation in their areas, on the levels of radioactivity in air and water, and on control and protective measures employed." Such baseline information, he concludes, would permit an intelligent appraisal of the extent of the present and future problems which the use of radiation may create and would permit the responsible agencies to determine their future course of action.

Other items in the July issue include articles on:

"Occurrence of Radon in Non-Uranium Mines in Colorado" (by P. W. Jacoe). The finding of appreciable quantities of radon in mines located several hundred miles from the nearest known deposit of uranium-bearing ore might indicate the possibility of undiscovered ore bodies nearby.

"Industrial Medicine Services in Italy" (by R. Vigliani). The number of industries in Italy which have their own medical services is increasing, although there is as yet no law compelling every industry to organize a medical service in its factories or establishing the rights, duties, or professional training of factory physicians.

"Occupational Health—A Joint Industry and Public Health Responsibility" (by Charles D. Yaffe). Industry in recent years has come more than halfway to meet the health agency in shouldering the responsibility for occupational health work.

"Occupation and Health" (by Seward E. Miller). Health hazards are reviewed in selected industries, such as chromate-producing, and in certain occupations, such as arc-welding in the steel shipbuilding industry.

Suspension Notice

Publication of *Occupational Health*, a monthly since 1940, has been suspended with its July 1953 issue as the result of reduction in appropriations. However, *Public Health Reports*—which in recent issues has presented papers on air pollution, human relations in industry, occupational and environmental aspects of various diseases, and industrial dentistry—will give increased attention to technical topics in occupational health. Official agencies, professional organizations, and teaching institutions not now receiving *Public Health Reports* should inquire of the Public Health Service as to their eligibility for official or free subscriptions. Other groups—and individuals wishing personal copies—should purchase subscriptions. *Use the subscription blank on the inside back cover of this issue.*

Recent issues of *Occupational Health* are available at 10¢ a copy from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C.

Elements of a Coordinated System Of Vital Records and Statistics

By HALBERT L. DUNN, M.D., Ph.D.

THE TEEN-AGER who needs a birth certificate to prove he is old enough to work and the demographer who needs global data to forecast world population are both served by the vital statistics system. Whether they are served well or badly depends on the functioning of a multitude of complex mechanisms—the local, State, Federal, and international units that make up the vital statistics system. These units collect and preserve vital records, perform essential services to the public in relation to the records, and produce the tabulated data that form the body of vital statistics.

Problems of Coordination

The most important problem facing the diverse mechanisms that make up a system of vital statistics is how to function as a coordinated whole. The individual units in the system may be likened to pieces of a mosaic. How can they be fitted together to form a complete picture, without blank spaces and overlapping? How can the methods and procedures of these

diverse units intermesh to produce a smooth-working, coordinated system?

“Coordination” is a much-abused word that should be defined at the outset. In this paper it does not mean the kind of coordination that implies a coordinator. The units that make up the vital statistics system are autonomous and will no doubt remain so. Any coordination that applies to these units must be the kind that develops through voluntary agreement on objectives, approaches, procedures, and the share of the total job that is appropriate to each.

The kind of coordination considered here is independent of organizational structure. It does not come by decree from above, and is not necessarily advanced by concentrating power in a centralized authority. For even though all record-collecting and statistical agencies might conceivably be centralized under a unified command, there would still have to be faced the original problem of coordination—of meshing the goals and procedures of statistics producers with those of statistics consumers, of relating the far-flung operations to the specialized needs of people outside the system for data on specific subject matter.

Agreement on Objectives

The problems of developing a coordinated system of vital records and statistics, therefore, should be approached primarily in terms of getting voluntary agreement by all the component units. What are the common objectives? Does each unit visualize the vital statistics system as a whole, not just as a miscellaneous mixture of little parts? In terms of the system as

Dr. Dunn is chief of the National Office of Vital Statistics, Public Health Service, and has been in charge of this unit, which was originally in the Bureau of the Census, since 1935. For the 12 years ended June 1952 he was secretary-general of the Inter American Statistical Institute and is now consultant to its executive committee. This paper was presented before the annual meeting of the American Statistical Association at Chicago, Ill., on December 27, 1952.

a whole, does each unit know where its own job begins and where that of the others leaves off? Are the right organizational pieces in the right places? In sharing the total job, have gaps been left?

Coordination is not a single problem. To obtain a fully complementary system of vital records and vital statistics, at least four distinct problems must be solved.

First, there is the matter of developing a proper working relationship among the various agencies producing vital records and vital statistics at each level of government—local, State, national, and international. We might call this intralevel or horizontal coordination. Much concern has been expressed, for example, about State and Federal governments in which various units allegedly publish noncomparable, unnecessary, or overlapping data that fail to meet much of the data needs of consumers. Criticism of this type in other fields of statistics led to the creation of the division of statistical standards in the U. S. Bureau of the Budget and to various other recommendations by commissions and other investigating bodies.

The second problem is to coordinate the objectives and practices of the local, State, national, and international vital statistics agencies. This interlevel coordination is of particular importance since vital statistics are produced in a vertical, step-up process, in which records or data move straight up from the smallest geographic divisions to the largest. For example, good vital statistics at the State level depend on records produced in local subdivisions; good national vital statistics depend on comparable material from 57 independent registration areas, and so on. Because of the massive vital record problem in this country, much work and effort have been directed toward vertical coordination, and considerable progress has been made in developing uniform standards, definitions, certificate forms, tabulations, and other procedures.

Orientation to Subject

The third problem is orientation of vital statistics to the broad variety of subject matter which they help to illuminate. Intersubject coordination is concerned with the use of vital statistics in relation to other data on the social, health, economic, geographic, and other char-

acteristics of populations. Special studies would give the answers to most of the problems in this area, and certainly the vital statistics system, operating at all levels of government, has the potential resources to conduct studies along many fronts. What studies are most needed? Which particular office is in the best position to carry it out? How can the study be so planned and conducted that its results will be applicable not only to the office that made it but to all other offices and agencies with similar problems? Certain types of studies are more appropriately made at the national level. A conspicuous example is a national health survey, machinery for which might be developed as a means of obtaining morbidity data from the general population to serve a variety of health needs. The skills incorporated in such a mechanism could be made available, upon request, to State agencies and nonofficial health organizations.

The fourth problem has to do with the coordination of various data that relate to the same individual, regardless of where these records were originally created and placed on file, so that the major events in his life may be linked and related to one another. Of necessity, such records are filed, if at all, where the event occurred, so that if he moves around much, his records may be scattered all over the United States and even in foreign countries. One office has his birth certificate, another his marriage license, while still others have his military, social security, and work records. His clinical records are scattered among the files of all the hospitals and physicians that have ever treated him. To pull copies of these records together, for the individual's own use, or for health control purposes, or for longitudinal studies, has become extremely difficult. Because of the political implications of attaching an identity number to the individual, and because of the substantial technical problems involved as well as differences of opinion as to the utility of such records, little is being done along this line.

Basic Terms Defined

It might be well to define our basic terms before discussing the elements that make for coordination:

"A coordinated system of vital records and

statistics" involves agencies at all levels of government that are responsible for the registration, collection, processing, and interrelation of vital records and the production of vital statistics derived from them. It includes mechanisms for improving methodology, for promoting internal consistency, efficiency, and economy, and for broadening the usefulness of vital records and statistics.

"Vital records" are certificates of death, fetal death, birth, legitimation, legal change of name, marriage, annulment of marriage, divorce, immigration, and naturalization.

"Vital statistics" are the statistical by-products of vital records.

"Related statistics" include population and morbidity statistics.

Immigration and naturalization records are included in the definition of vital records because they are recorded in much the same way and are used for similar purposes, even though historically they have not been handled by the same branch of government that handles other vital records.

Many other public records on individuals are officially collected and maintained—such as those of military service, social security, and professional licensing. As circumstances warrant, these might be considered for possible coordination with vital records.

It will be noted that morbidity statistics are classed as related statistics rather than as vital statistics. By historical accident both morbidity and vital statistics are often produced by the same government agencies, but their fundamental nature is quite different. Morbidity statistics are, of course, closely linked to vital statistics by a common classification for sickness and cause of death. But the legal and personal uses of morbidity records are extremely limited—most people, in fact, never see their own sickness records. Even though morbidity statistics may be part of the workload of a vital statistics agency, they are not an intrinsic part of the vital statistics system.

Elements of a Coordinated System

The importance of vertical coordination has already been mentioned, and the accompanying table is a first attempt toward mapping a distribution of the responsibilities of the several levels

of government with respect to vital statistics. In presenting my personal viewpoint as to where the primary responsibilities lie, it is not my intention to suggest a limitation of activity or functions of any of the units. Certainly there is room for constructive thinking on each of the elements at all levels of government.

Each person operating in a vital statistics office—whether at the local, State, national, or international level—tends to think of his own particular problems as discrete in nature, and his own office as a sovereign body. The time has come, however, when it is necessary for all those who hold responsible positions in units of the system to reexamine what they are doing with reference to the system as a whole in terms of the impact on the users of the records and of the resultant statistics. Perhaps the great advances of the future will come largely from a better concept of the system as a whole and a realization of the true functions, responsibilities, and potentialities of its parts.

In a dynamic field like vital records and vital statistics, which must continue to change in response to the needs of an ever-changing world, it will never be practical to set final goals. The 10 elements described below and summarized in the table are not to be regarded as final goals. They are proposed rather as basic components of the "next stage" in developing a coordinated system of vital records and vital statistics.

Completeness, Accuracy, Timeliness

The first element is completeness, accuracy, and timeliness in the registration of vital events. Behind these words is a never-ending struggle to obtain and secure the active cooperation of several hundred thousand official and semipublic personages who fill out certificates—physicians, hospital personnel, midwives, coroners, funeral directors, and others. To get in this country a reliable statement of the cause of death, for example, requires the understanding and cooperation of some 210,000 practicing physicians, who need instruction and reinstruction with every revision of the International Classification of Diseases, Injuries, and Causes of Death. To achieve satisfactory birth registration in two-thirds of the States has taken a full half-century of patient effort with physicians and

Elements of a Coordinated System of Vital Records and Statistics

ELEMENTS	Local responsibility	State responsibility ¹
1. Completeness, accuracy, and timeliness of vital records (except immigration and naturalization).	Primary responsibility for accurate and timely collection.	Primary responsibility for developing and maintaining State and local procedures in collection, and for consultation.
2. Preservation and protection of vital records, and service to the public.	Participation with State vital statistics office.	Primary responsibility for methods used, results obtained, and services rendered.
3. Focus of coordination: Definitions, classifications, laws, certificate forms, interstate and international procedures, and consistency control of vital statistics.	Participation with State vital statistics office and application of approved methodology.	Participation with NOVS in development of standards; primary responsibility for the application of methods and for consistency within the State.
4. Training and education of personnel.	Training programs for local purposes.	Inservice training of State and local personnel; participation in national training programs and academic training.
5. Vital records of American citizens abroad and of naturalized citizens at home and abroad.	Collaboration with State programs.	Collaboration with national agencies; and representation of local use requirements in national programs.
6. Annual and cyclic vital statistics (including life tables).	Production of local statistics; collaboration with State programs.	Primary responsibility for production of State and local vital statistics, including methodological research.
7. Special studies via vital and social statistics.	Local studies.	Planning and execution of State and local studies.
8. Population statistics and population estimates.	Participation with State on methods of research and collection of data.	Participation with Bureau of the Census and NOVS on methods research and collection of data.
9. Morbidity statistics, including morbidity reporting and health surveys.	Administrative responsibility for local morbidity reporting and local health surveys.	Primary responsibility for morbidity reporting and health surveys. Participation with Public Health Service on methods of research and development of standards and procedures.
10. A national vital statistics index (when and if established by law).	Participation with State vital statistics office.	Participation with Federal agency in developing standards and methods for establishing, and primary responsibility for implementing State portions.

¹ Includes Territories and independent registration cities (New York City; Boston; Washington, D. C.; Baltimore; and New Orleans).

midwives, as well as continuous education of the general public. The battle in the remaining States should be won within the next decade.

The drive toward complete and accurate registration was given a decisive impetus early in World War II, when defense plants and public agencies of all kinds insisted on proof of citizenship and other pertinent facts. As a re-

sult, State and local offices were swamped with demands to produce certified copies of records. This led to two permanent gains—a new public awareness of the value of complete and accurate registration, and more efficient procedures in State and local offices to cope with the increased public dependency on vital records.

Registration is primarily a local responsi-

and the Locus of Responsibilities for These Elements

National responsibility	International responsibility	ELEMENTS
Conduct of special studies aimed at improving methods, consultation service on request.	Establishment of general principles to meet international needs.	1. Completeness, accuracy and timeliness of vital records (except immigration and naturalization).
Conduct of methods research, maintenance of exchange of information, and consultation.	Establishment of general principles to meet international needs.	2. Preservation and protection of vital records, and service to the public.
In collaboration with States, primary responsibility for standards and practices.	Primary responsibility for international coordination of practices.	3. Focus of coordination: Definitions, classifications, laws, certificate forms, interstate and international procedures and consistency control of vital statistics.
Establishment of training programs and centers, participation in international programs and collaboration with schools of public health.	Establishment of training programs and related activities.	4. Training and education of personnel.
Establishment of a Federal focus for vital records involving, among others, the Immigration and Naturalization Service, State Department, and NOVS.	Responsibility for the coordination of vital record practices between nations.	5. Vital records of American citizens abroad and of naturalized citizens at home and abroad.
Primary responsibility for production of national vital statistics, including methodological research.	International statistical publications and exchange of information on statistical methods between nations.	6. Annual and cyclic vital statistics (including life tables).
Responsibility for developing special studies of national significance and collaboration with States.	Responsibility for special studies of international significance.	7. Special studies via vital and social statistics.
Production of population data a primary responsibility of Bureau of the Census. Small area estimates should be produced in collaboration with NOVS and States.	Promotion of national censuses having the degree of consistency essential for international needs.	8. Population statistics and population estimates.
Primary responsibility for national public health surveys and national morbidity reporting standards, in collaboration with State health departments.	Promotion and implementation of a worldwide morbidity reporting mechanism and promotion of national health survey mechanisms.	9. Morbidity statistics, including morbidity reporting and health surveys.
Primary responsibility for developing standards and methods to be used, and maintenance of consistency control in its operation.	Responsibility for developing and promoting standards and methods to be used consistent with international needs.	10. A national vital statistics index (when and if established by law).

bility. A late State registrar put this point most aptly: "The local registrar knows the new baby of the Jones family as Johnny Jones; the State registrar knows him as a certificate and a number; and the National Office [of Vital Statistics] knows him as a statistic." Only at the local level do vital records reflect real people, living in real places. If the record is to be complete, the local registrar must be on the job. If

hospital, physician, funeral director, or midwife fails to fulfill responsibilities, it is the local registrar who, with tolerance and patience, must explain, persuade, and follow up until the person mends his ways.

This is a difficult and important task, carried out by part-time workers usually paid on a "per certificate" basis. It takes understanding on the part of the local registrar, and considerable

devotion to a cause. This does not come of its own accord. To develop such a group of local registrars is a prime responsibility of the State vital statistics office. It means carefully prepared manuals of instruction for the local registrar. It means field visits by the staff of the State office and consultation between them and the local registrar. It means occasional conferences of local registrars and formalized periods of instruction. But most of all, it means the creation of an awareness of the importance of the task. Everyone does a job better when he knows why it is important and how it fits into a larger pattern of services.

Preservation and Protection of Records

Preservation and protection of vital records and service to the public have long been a major responsibility of the State registrar. Huge concrete and steel vaults are located in almost every State to house the precious documents and to protect them from fire and flood. Toughness of paper, durability of ink, and protection against mildew and mold are matters of constant concern.

Protection of records also involves safeguarding them against alteration or theft. In the old days when practices were looser, it was not unknown for a person who was permitted to search the bound volumes of certificates to rip out and carry away one of these important documents. Imagine the temptation it would be to a souvenir collector if the birth certificate of one of our American Presidents were under his itching fingers, with no one watching!

Unwarranted disclosure of facts on certificates might embarrass or damage individuals. The registrar must therefore restrict access to records to persons who can demonstrate "a direct, tangible, and legitimate interest" in the specific record. At the same time he must minimize red tape in providing certifications to those who do have such an interest. It may be assumed that everyone wants ready access to his own record or to a certified copy, so that he may present it to the various public and private agencies that require it as a condition of employment, old age pensions, and other benefits. At the same time he may want the record withheld from individuals or agencies such as the press,

the courts, and law enforcement agencies. The framing of laws and regulations that will protect the confidentiality of the record and at the same time keep it accessible to those with a legitimate interest in it is one of the knottiest problems in the registration field. Whether a common ground can be found on which the many conflicting interests can meet is now being explored by the American Association of Registration Executives, the organization of State registrars.

Focus of Coordination

The third essential element is a focus of coordination, including definitions, classifications, model laws, certificate forms, interstate and international procedures, and control of consistency of national vital statistics.

The coordination of vital records and the maintenance of satisfactory consistency in the national vital statistics are responsibilities which must be focalized in a single national agency having the authority and means to implement them. Prior to 1946 the national focus was the Bureau of the Census, which served mostly as a statistical focus. In that year, when the Congress transferred the national vital statistics activity to the Public Health Service—in line with the fact that State and local jurisdiction of vital statistics resides in health agencies—the policy was made clear that the Federal agency should also serve as a focal point in resolving difficulties and inconsistencies in registration practices.

After years of trial and error, the National Office of Vital Statistics came to the realization that the way to serve as a focus of coordination is to engage in cooperative agreements resulting from joint planning. The answer to the need for a national focus of coordination has emerged through the development of the Public Health Conference on Records and Statistics. The conference is a permanent organization, recognized by the Association of State and Territorial Health Officers as a body competent to deal with problems in the field of vital and health statistics. It is supported jointly by the States and the Federal Government, with a secretariat furnished by the National Office of Vital Statistics. Its decisions are its own and are entered into by

agreement, after opportunity for free discussion has made joint planning a reality.

In large measure the promotion of agreement on procedures and related matters is the responsibility of the national focal point of coordination. But it is interesting to realize that a similar mechanism for coordination on a world-wide scale is now emerging through the action of the World Health Organization, which has urged all nations to set up national committees on vital and health statistics. The establishment of such committees in many nations of the world, with the aim of bringing about direct participation by national technicians in the technical problems of an international nature, has launched yet another mechanism to promote better coordination. The first international conference of national committees on vital and health statistics has been scheduled for the fall of 1953.

All these recent developments lay heavy emphasis on participation and consent of all parties concerned, for the coordinating responsibility should not be exercised arbitrarily or unnecessarily. In essence, this means that each higher level of responsibility and authority should justify the need for introducing uniformity into a particular procedure before this right is surrendered by the technicians who operate closer to the people concerned. Unless this precaution is observed, the system as a whole will lose its flexibility and adaptability. Complete uniformity in all vital record and vital statistics activities is neither necessary nor desirable. Custom-tailoring in basic patterns, with flexibility to adapt the procedures community by community to fit special circumstances, is often the only way to meet registration problems.

At the same time the National Office of Vital Statistics cannot relinquish authority for control over the consistency of national vital statistics. Vital statistics of a country have little value unless they are internally consistent. In production of national vital statistics by the use of the statistics produced by State offices, the requirement of consistency becomes all-important. Agreements are not enough. Consistency in practices is so vital that the degree of consistency must be checked adequately and

continually, and alternative procedures must be available for use if consistency is not maintained.

Training and Educating Personnel

The fourth element of a coordinated system is to provide means of training and educating personnel. Vital statistics offices at all levels are handicapped by a severe shortage of personnel with sufficient academic and practical training in the techniques of vital registration and vital statistics. Training is a matter of deep concern to all levels of government. It is carried out through in-service training programs when these are practicable, through formal courses in public health schools, and through organized seminars designed to teach practical skills. The Point IV program at the international level is an effort directed at developing knowledge and skills through grants-in-aid, training centers, consultation, and other means.

Citizens Abroad and Naturalized Citizens

Vital records of American citizens abroad and of naturalized citizens at home and abroad should become an integral part of a coordinated system of vital records and statistics, if it is to be effective as a whole. A conservative estimate of the number of American citizens outside the United States during 1952 would be over 1,500,000. While abroad, many of them marry, have children, obtain divorces, or die. Records of these events are made and filed according to a multitude of foreign laws and practices; certain other records may be made—by various Federal and State agencies—when the citizen or his family comes back. But there is no single national focal point of coordination, no single custodian of such records. Considerable confusion and hardship result, for example, when a family returns from a tour of duty overseas and attempts to settle down in an American community. Are the children citizens? Are they of school age? If the parents have no records to prove such facts, where can they get them? Similar problems plague naturalized citizens, and families that have adopted children born overseas. Undoubtedly, Federal legislation will be required to straighten out this problem. While details remain to be worked

out, those who have studied the matter are in general agreement that coordinating and custodial responsibility must be vested in a single Federal agency.

Annual and Cyclic Records

Means for coordinating the planning and production of annual and cyclic vital statistics are a sixth essential element of a coordinated system. Most of the cyclic production is on an annual basis, but for many series the cycle may be shorter—for example, the “disease year” for polio and other diseases—or longer, as for the variety of series based on the decennial census. The objective is not only to produce these series at maximum efficiency but to shape the output of facts so as to enrich their significance and value to society. While the National Office of Vital Statistics has primary responsibility for this type of coordination, it must work closely with State and international agencies, including consuming agencies as well as producers.

Special Studies

Means for coordinating the planning and parceling out of vital statistics special studies are a seventh element of a coordinated system. In its historical development, vital statistics organizations have emphasized massive, overall statistics—based on all birth certificates or all death certificates, and so on. A way must be found to obtain greater balance and variety by replacing this approach, wherever practical, with sampling statistics and special studies. Instead of including every item on all certificates, desired supplementary items might be added in only one or two States, or for short periods of time. Through these and other types of studies on limited groups, a broad variety of sample data could be assembled from which to interpret the massive data. Studies undertaken in one area should be designed so that results will be applicable in many other areas. By a planned distribution of the work among statistics agencies at all levels of government, the significance of the total output could be greatly increased.

Population Estimates for Small Areas

An eighth essential element is the provision of population statistics and population esti-

mates for small areas. Adequate population data for computation of vital statistics rates are indispensable to the vital statistics field. The production of national population census data and estimates is a responsibility of the Census Bureau. Since the greatest use of both health statistics and vital statistics is made at the local level, population estimates must also be made available for small areas as well as for the country as a whole and for the States. The lack of adequate estimates of population for small areas has recently brought about an active and aggressive movement of State registrars and public health statisticians to promote a mid-decennial population count in 1955, but the prospects of achievement appear dubious.

Resources should be found to approach the problem of developing new procedures for estimating the population of small areas. This would seem to require a cooperative program on the part of the States, the Bureau of the Census, and the National Office of Vital Statistics to explore the potentialities of school census material and every other available source of relevant data.

Morbidity Statistics

Morbidity statistics, including morbidity reporting and health surveys, are closely related to vital statistics, though not an integral part. As mentioned earlier, they are linked to vital statistics through a common classification for sickness and cause of death. In addition, both morbidity and mortality data are needed for case-fatality rates.

Sampling studies and health surveys are also closely related to vital statistics. It is necessary for both sickness statistics and those of birth, death, marriage, and divorce to relate such events to the way people live. In the future, vital statistics must be concerned to an increasing degree with sampling studies designed to broaden interpretation of the data. In particular, study should be made of the population type of survey mechanism, which offers a means of filling the gaps in our knowledge and, at the same time, holds forth the possibility of broadening the interpretation and usefulness of existing reservoirs of clinical, hospital, and health data.

Cross-Indexes

In the long run, a coordinated system of vital records and statistics might well take advantage of the values inherent in cross-indexing the conglomeration of vital records that are created for each individual throughout his lifetime. Such an index, operating on a national scale, may ultimately be needed not only to serve the record needs of our mobile population, but also to facilitate the longitudinal and followup studies required for medical research and public health. Fear has been expressed by some persons that such an index might serve repressive purposes, but many others feel that the strength of our democratic institutions gives sufficient security to the individual. To bring a national index into being would require, of course, a Federal enabling act, a national focal point, and a series of complementary State laws and regulations.

Conclusion

These then are some of the elements which deserve consideration in the formulation of a coordinated system of vital records and statis-

tics. But whatever the number of elements, however defined and located, there is no solution to the complex and enormous problems posed to the producers and users of vital records unless considerable uniformity can be introduced into the methods, forms, and definitions used by localities, States, nations, and the international agencies. Great strides have been made in development of a focal point which would work consistently for the coordination of vital records throughout this country.

In the immediate future lies a much more intensive campaign to improve the coordination of vital statistics through the extensive development of special studies and health surveys aimed at broadening the interpretation and significance of vital statistics in relation to other types of social and health information.

Perhaps most important of all is to stimulate the creation of a concept of a coordinated system of vital records and vital statistics. The concept of such a system must be developed as a whole, and it must be a concept to which all involved can wholeheartedly subscribe and which—primarily—will satisfy the needs of its millions of users.

Assistants to the Secretary Appointed

Georgia France McCoy of Oklahoma City, Okla., has been appointed assistant to the Secretary of the Department of Health, Education, and Welfare.

Since 1949, Mrs. McCoy has held administrative and research positions in the department of physical medicine and rehabilitation at the New York University-Bellevue Medical Center in New York City. Recently she was executive administrator of a gerontological service at the medical center.

Mrs. McCoy has had many years of public service in administering social work activities.

Donald M. Counihan has been appointed assistant to the Secretary of the Department of Health, Education, and Welfare. He will serve as legislative liaison officer.

Mr. Counihan received his law degree from Marquette University in 1946 and engaged in private practice in Milwaukee prior to serving as administrative assistant to U. S. Representative Charles W. Kersten of Wisconsin in 1947 and 1948. In private practice in Washington, D. C., before his recent appointment, Mr. Counihan is a member of the American, Wisconsin, Milwaukee, and District of Columbia Bar Associations.

Investigation of Jute Imports As Potential Plague Source

By EDGAR W. NORRIS, M.D., LEWIS B. SCHNEIDER,
LELAND J. HANCHETT, M.D., CHARLES E. KOHLER,
and WILLIAM F. BUREN

SEVERAL plague outbreaks along the west coast of South America over the past 20 years have been traced to infected fleas found in shipments of jute bags from India (1,2). It has been demonstrated also that infected *Xenopsylla cheopis* fleas can survive and transmit their infection after being trapped in bags for 30 days or more under optimum conditions of temperature and humidity (3). Since the United States imports from India approximately 350,000 tons of jute products annually, the possibility of plague introduction through this medium seemed to warrant investigation.

Between August 1949 and March 1951 the quarantine stations at San Francisco, Calif., and San Juan, P. R., conducted systematic examinations of all jute imports to determine whether or not evidence could be found of flea infestation. At San Francisco studies were conducted also to determine the survival rate and the longevity of *X. cheopis* under conditions as they prevail in the baling and shipping of jute products.

Methods Employed

At San Francisco shipments of jute from India consist principally of bolts of hessian cloth in large bales and arrive at weekly or bi-weekly intervals. Through the cooperation of

Dr. Norris is medical officer in charge, and Mr. Schneider is quarantine inspector, of the San Francisco Quarantine Station. Dr. Hanchett is medical officer in charge of the San Juan Quarantine Station, and Mr. Kohler and Mr. Buren are sanitarians assigned to the Communicable Disease Center activities in San Juan, P. R.

the importers random bales were selected. The wrappers were removed and random bolts of the jute cloth were taken out for examination. The wrappers and the jute cloth were unraveled, shaken, and brushed over a white bed sheet. These brushings were assiduously searched with high-power magnifying glasses for insects or parts thereof, and the inspectors were constantly alert to detect any insect movement. To test the keenness of the inspectors' perception, on several occasions known numbers of dead fleas were scattered about in the jute debris which had been searched previously with negative results. Upon reexamination of this debris the inspectors recovered all of the fleas which had been deposited.

Three hundred and seventy-six examinations were made of wrappers and samples of jute cloth aggregating 152,000 yards taken from 880 random bolts removed from 179 random bales. Any insects or particles suspected of being parts of insects were collected and delivered for identification to F. M. Prince, entomologist, at the Western Branch Communicable Disease Center Laboratory. No fleas, alive or dead, were found nor were any parts of fleas identified by microscopic examination.

At San Juan the jute imports consist principally of manufactured bags or gunny sacks. The examinations there included a microscopic search for fleas in all of the material shaken and brushed from the bags. The brushings were thinly spread over white paper which had been coated with a film of castor oil and tacked to light plywood for ease of handling. The low-power objective of a wide-field microscope was employed, using a very bright focusing light to illuminate the field. The examinations and identifications were made by an entomologist. The wrappers of 67 bales and a total of 4,994 bags were examined. One hundred and eighteen insects were found, of which 89 were alive, but all were identified as being of genera and species indigenous to Puerto Rico; none of these insects were fleas.

Observations on Vitality of *X. Cheopis*

In the study of the longevity and survival rate of *X. cheopis* under actual conditions of

processing and overseas shipment, conducted by the San Francisco station, the fleas were furnished by the Western CDC Laboratory. On September 15, 1949, 30 live, well-fed, noninfected *X. cheopis* were placed in each of two 9- by 14-inch cotton bags, which then were securely closed. One bag was placed between layers of jute about midway in a bale, and the second was placed under the first layer of jute. The bale was then wrapped, pressed in an electrically powered baler, sewed, and bound with flat metal strips. It was loaded in a cargo hold of a vessel of the Pacific Far East Line bound for Manila, Hong Kong, and Okinawa, and return. When this vessel returned to San Francisco 49 days later, November 3, 1949, the bags of fleas were removed and examined at the laboratory. From one bag 29 fleas were recovered and from the other, 28 fleas; all were dead. The 3 missing fleas were presumed to have escaped before the bags were tied prior to shipment.

On November 10, 1949, 150 live, well-fed, noninfected fleas were placed in a small cotton bag containing a small amount of wood shavings. The bag was secured, placed in a cardboard container and encased in a wooden box. This was placed in the hold of a vessel of the Matson Navigation Company bound for the Hawaiian Islands. Upon return of the vessel to San Francisco on December 3, after a voyage of 23 days, the box was removed and 146 fleas were recovered; all were dead. Four of the original 150 fleas were unaccounted for. Upon microscopic examination, the bodies of the recovered fleas did not appear to be undernourished, and it is believed that death was not due to starvation.

On December 15, 1949, 100 well-fed, noninfected fleas were put in a wooden box in which two freshly cut apples were placed to supply moisture. This box was shipped on a round trip to the Hawaiian Islands in the hold of a vessel, and 22 days later, upon return to San Francisco, 100 fleas were recovered from the box; all were dead.

Effect of Extreme Pressure on *X. Cheopis*

Tests were performed also at San Francisco, through the cooperation of the Western CDC

Laboratory and one of the importers, to determine how much the pressure of the baling process may contribute toward the mortality of the fleas trapped inside the bales. Three cotton bags each containing 25 *X. cheopis* were placed at different levels inside a bale of jute wrappers which was then compressed under a pressure of about 8,000 pounds—less than the pressure normally employed in the commercial baling of hessian cloth. That experiment was performed on two occasions, November 15 and December 15, 1949, with practically the same results. At the end of 10 minutes following the application of the pressure by the electrically powered mechanical baler, approximately 33 percent of the fleas were found dead; at the end of 1 hour 50 percent were dead and at the end of 72 hours more than 75 percent were dead. These observations seem to indicate that the pressure exerted in the baling process is an important factor in reducing the chances of survival of fleas trapped within bales of jute products.

Conclusions

The variations of temperature and humidity in surface vessels, incident to changing latitudes and passage through various ocean currents, are inimical to the rat flea in the absence of its natural host. Its survival is further jeopardized when trapped in jute and subjected to the pressure exerted in the baling process. If well-nourished, noninfected fleas have little chance of survival under these conditions, plague-infected fleas should be expected to have even less chance because of the additional hazard of the bacterial process causing obstruction of the stomach. Due to this blockage, the average length of life of *X. cheopis*, after being infected with plague, is only 14.5 days under relatively favorable conditions (4).

Past experience with the tremendous annual importations of jute cloth and bags and the observations presented in this report seem to validate the statement made by the Public Health Service in 1937, that "While it may not be without the realm of possibility that, under favorable meteorological conditions, fleas with-

out a host can serve as reservoirs of plague infection, carry it over long distances and later, under favorable conditions, transmit the disease, such danger is probably insignificant in comparison with the danger from infected fleas carried by rats" (5).

To the Professional Public Health Worker

You, like the specialist in medical and other fields of science, know how important it is to be informed on current knowledge in your specialty. And, for the most part, you rely on the first-hand availability of the leading journals and periodicals in your specialty.

But as more becomes known of public health practice and research, the more complex this science becomes. There comes too the need to relate the activities of all its component disciplines—the members of the family of public health—one to the other, and each to the whole. And for each specialist there is a need to read regularly the journals devoted to unifying the family of public health. *Public Health Reports* is such a journal.

In Sanitation

By MARK D. HOLLIS, C.E.

UNTIL RECENTLY, three classic approaches have dominated the public administration of sanitation. The most primitive approach by the sanitarian was to carry a big stick. A more sophisticated approach was to speak softly and carry the big stick in a velvet glove. With the advent of epidemiology, it proved effective to speak cogently and to carry a slide rule. Today we have reached a point where public officials may expect sanitation to prevail mainly on a cooperative basis. The pressure to comply with approved sanitation practice now rises less from a fear of epidemics or of legal sanctions and more from a desire for good living and common realization of mutual interest. The activities of official health inspectors have been augmented and to a great extent reconstructed by the emergence of sanitary habits, practices, and customs in the general population and in industry.

The emergence of the modern mood in sanitation has stimulated the following comments on its development.

From Resistance to Collaboration

At the outset, it may be well to recall that advances in sanitation never have come easily. It is only human to resist change, and, to a moralist, resistance seems to be compounded when the change is beneficial. Impatient with such resistance and perhaps imbued with a

deep sense of righteousness, the sanitarian in the past tended to resort to police power rather than rely upon persuasion.

The dilemma of the early sanitarian was expressed in Lemuel Shattuek's eighth recommendation: that "Local Boards of Health endeavor to carry into effect all their orders and regulations in a conciliatory manner; and that they resort to compulsory process only when the public good requires." He commented, "In carrying a public measure into effect, the favorable opinion and cooperation of the people is desirable." But Shattuek did not feel that such cooperation was essential. Rather, he cited the summary power of the Commonwealth and its "duty to interfere" to remove a health hazard. "Public safety requires it—human life demands it," he wrote (1).

Sir Edwin Chadwick, the author of the modern sanitary awakening, was deposed from office for his zeal (2). His determination to clean up London created such a storm of opposition that the *London Times* commented in 1854, "Aesculapius . . . in the form of Mr. Chadwick [has] been deposed, and we prefer to take our chance of cholera and the rest than be bullied into health—England wants to be clean, but not to be cleaned by Chadwick."

So much has the attitude toward sanitation changed that today the public appeals to the professional sanitarian and the public health official for advice and guidance. As to sanitation of interstate carriers, a direct responsibility of the Public Health Service, there has been a distinct gain in cooperation even within the past 5 years. For example, the Joint Com-

Assistant Surgeon General Hollis is deputy chief of the Bureau of State Services and chief engineering officer of the Public Health Service.

mittee on Airline Sanitation, composed of representatives of the Public Health Service, the airlines, and catering companies, has found that commercial interests are eager to establish and comply with the committee's recommended sanitary requirements. These are now advanced almost to the point of formal publication. Progressive leaders of the restaurant trade have shown a similar spirit. Several railways have provided dining car supervisors, trained in sanitation practices, to conduct inspections to meet and even supplement Public Health Service requirements. Progressive railways go well beyond the essential requirements of dining car sanitation. Such efforts permit a public inspector to become more of a guide, teacher, and counselor and less a detective or policeman.

An increase in private assumption of responsibility for sanitation certainly does not warrant the abdication of State responsibility. Nevertheless, evaluation of health department sanitation services in the future may well consider how much of the activity conducted at public expense might be conducted by private enterprise with greater efficiency and economy. The Public Health Service's evaluation of the big stick policy has led to placing primary and major emphasis upon education and technical guidance. All the Service handbooks on sanitation practice and standards stress the technique, the purpose, and the advantage of sanitation rather than legal requirements and penalties.

The fall of Chadwick did not terminate the assumption of summary power by State authorities, nor did it quench the zeal of other sanitarians who fought for public health reforms, with or without power to install them. Meanwhile, experience has demonstrated what the prophetic Shattuck assumed that "the favorable opinion and cooperation of the people is desirable." We have learned to appreciate how much enforcement is an extravagant waste of time that might be spent more productively on guidance. We have come to understand the frustrations in a policy that condemns the sanitarian to repeated inspection of chronic violations. And we have come to see that the development of a cooperative program of sanitation standards, education, and compliance will

reduce routine inspections and enforcement actions by health officials and improve sanitary conditions.

This transition in policy did not occur overnight. It had its origin in the first stirrings of modern sanitation. We are not even near the end of the passage. Still it seems that a century of public health practice has brought to adolescence if not to maturity the ideal of sanitation imposed by self-discipline and cooperative action.

Institutions for the Modern Mood

In response to this changed situation, we have developed relatively new health institutions. These institutions appear to be genuine mutations in the social evolution of public health, if their development can be said to resemble the origin of species. Not only are they genuine mutations, but they were to be expected. Social history accepts the fact that the modern corporation, the cooperative association, the trade unions, and the industrial unions were born to meet emergent economic needs, and that interstate authorities, regulatory commissions, and associations for trades, professions, and governments were formed within the past few generations to meet specific administrative needs. The necessity for such new institutions today may seem obvious, but few are able to discern such a need when new social forms and institutions are in embryo.

The field of public health in the past century has had other mutations. We have seen the development of the professional organizations of medicine, sanitary engineering, nursing, and dentistry, the formation of boards of health and departments of health, the growth of public hospitals and health centers, and a proliferation of research institutions, clinics, laboratories, and insurance systems. These institutions have resulted from a broadened appreciation of health practice. The recognized domain of health work has become so broad that today's employees in public health agencies and the professions named above account for but a small part of the total economic activity devoted to protecting and improving the health of the community.

Since the beginning of the public health

movement, there has been a valuable auxiliary force of volunteers, from Florence Nightingale to a host of national and community voluntary associations. Voluntary organizations today play a most useful role in securing popular understanding of public health programs, and for supplementing private health services with experiment and research.

In addition to such voluntary public and professional organizations, we have a major category of those who are public health servants largely by association. They are not always conscious members of the open conspiracy to improve public health. Much of the important activity in fields bearing directly on public health is under commercial management which is often unaware of the full importance of its health role, because it operates primarily with technical or economic objectives. Such management is neither indifferent nor hostile to public health. It is simply for the most part not primarily directed toward health goals. The gain to health is coincidental if not accidental. Nevertheless, no one will deny the contribution of such enterprises as soap, paper, pesticide, cement, or steel production to the elevation of health conditions. In the large sense, nearly everyone is in business for our health. Usually, where economic and technical enterprises have come in direct contact with the public health profession, as in the milk and food industries, managerial cooperation with health authorities has been predominantly sincere and effective. In the control of pollution in water and in atmosphere some of the most practical and effective support is found among enlightened managerial figures who believe that what is good for the community is best for private industry.

A Meeting Ground

In this situation, it was to be expected that institutions would emerge to provide a common ground where various elements, whether engaged directly or obliquely in public health work, would meet to work out a common program. The need for such a meeting place has been intensified by the extraordinary specialization and compartmentalization of health work.

The need for a meeting ground was suggested also by the fact that, in this complex, specialized society, the business of bringing together strangers who ought to meet in a common interest has in itself become something of a specialty.

Consequently, allied interests have developed such institutions as the National Sanitation Foundation, the National Safety Council, the Public Health Committee of the Paper Cup and Container Institute, the Chemical Products Labeling Committee, the 3-A Committees on Sanitary Standards for Dairy Equipment, and many others. While there are many variations in their structure, it is clear that these organizations are a new breed. Not purely public, private, professional, or commercial, their distinguishing characteristic is that they represent a joint effort to blend the public interest, prevailing legal requirements, the best scientific judgment, and sound commercial practice in the economic activities that bear on sanitation.

The Public Health Service finds itself involved with such organizations in several ways. Representatives of the Service work with representatives of commercial interests and others on multilateral committees organized by such responsible agencies as the National Research Council. We also form bilateral joint committees with industry, such as the one which is drafting a recommended code for poultry sanitation. And we serve as consultants to unilateral industry committees such as the committee which is developing sanitation standards for the baking industry. With so many possible permutations of such arrangements, each of these organizations is free to determine what operating structure best serves its purpose. The chances of successful cooperation among the allied interests would seem to require joint contribution of funds or services from the respective public, legal, scientific, and commercial interests. For this reason, and because of its association with the Committee on Food Equipment Standards, the National Sanitation Foundation is a good example of the cooperation that seems likely to characterize a great part of sanitation activity in the future.

Like these other organizations, the National Sanitation Foundation was an organic response

to a social challenge. The men who have assisted its growth declare that they have been the instruments of this response, rather than the authors.

The need for a common meeting ground for the allied interests in this phase of sanitation was not obvious to all. Nevertheless, it was a genuine need, a popular need. This need could not have been satisfied by existing agencies in public health, working by themselves alone. The overburdened health departments too seldom have time to look up from their heavy tasks to see new opportunities ahead. And professional organizations cannot seek to meet the needs of industry any more than a trade association can presume to serve a profession. But an independent organization like the National Sanitation Foundation can combine these interests. Such organizations make it easier for representatives of industry, the professions, and public agencies interested in a particular phase of public health work to combine their energies and to achieve common objectives, such as uniform equipment standards for the food service industry. Their services may be broadened even further to the extent that labor and consumer organizations take part in their future activities.

Uniform Sanitary Standards

The need for consistent standards for food equipment gave the National Sanitation Foundation its first concrete and specific enterprise. Similarly, professional societies and public health agencies have made many useful contributions to resolving the need for standards in this field. A great deal of progress has been achieved by the milk industry and health agencies working through such groups as the 3-A Committees on Sanitary Standards for Dairy Equipment. Similar joint action has been taken by those associated with the Baking Industry Sanitation Standards Committee. Also, many individual food equipment companies have been working with public health agencies directly to develop sanitary standards for their respective products. The Foundation was founded in response to a feeling among members of the food industry that a broad approach

was required to progress specifically against variations and gaps in municipal regulations and their interpretations. The available machinery for resolving the variations and filling the gaps in such regulations did not satisfy the needs of the responsible interests concerned. For the purpose of accelerating the solution to some of these difficulties by practical, democratic, and reasonable means, a cooperative body was formed on invitation by the National Sanitation Foundation.

This body, the Joint Committee on Food Equipment Standards, represented five national professional sanitation organizations and the Public Health Service. Included were the International Association of Milk and Food Sanitarians, the National Association of Sanitarians, the Engineering Section of the American Public Health Association, the Conference of State Sanitary Engineers, and the Conference of Municipal Public Health Engineers. The committee was organized following the Foundation's first National Sanitation Clinic, a 1948 meeting in Ann Arbor. More than 400 guests of the Foundation met in this clinic to discuss food sanitation. Participants in this meeting included authorities from local, State, and Federal Government agencies, from commerce and industry, and from universities and professional associations. They recommended development of standard practices and equipment criteria, and simultaneously the establishment of a testing laboratory that would serve industry, government, professionals, and the public.

The fact that the National Sanitation Foundation is supported by contributions of funds from industry and services from government, professional associations, and the university world puts it at the fulcrum in such a balance of interests in sanitation.

The activities of the Joint Committee have been described elsewhere (3). It is sufficient to note here that the series of standards for the food industry which were worked out by the committee in consultation with industry, government agencies, and professional societies are being published by the National Sanitation Foundation. New equipment which meets these standards will be authorized by the testing laboratory to carry the Foundation's NSF

insigne, as an aid to all concerned with appraising equipment design and construction. Thus, the doubts and problems of the industries and the regulatory agencies both should be materially reduced, because there is every ground for confidence that as much cooperative effort will go into the application of these standards as went into their creation.

The first standards published apply to soda fountain and luncheonette equipment (4). Standards for food service equipment followed (5), and standards for spray-type dishwashing machines are next in view. The dishwashing machine standard, based largely on research conducted since 1944, has been delayed pending further study. All such publications are a welcome and useful supplement to other efforts to raise sanitation levels, such as the operating codes recommended by the Public Health Service.

Since manufacturers and health authorities joined in drawing these standards, it is expected that they will be acceptable to every city and State health department and that they will resolve differences among local health ordinances governing such equipment. This achievement is indeed a milestone in the progress of health services.

The Means to an End

But the significance of this movement does not lie with the standards so much as with their purpose—to contribute to health by improving the American environment. Standards are not an end in themselves. They are merely a means to improve living and working conditions.

Organizations like the National Sanitation Foundation, by such practical devices as these publications, may labor aggressively and experimentally for progress in public health. With a university background, they can be both informed and impartial. They may contract freely, as private institutions, to work on a specific problem proposed by a responsible source. At the same time, they should be bound by professional and official associations to seek the public advantage.

Through its laboratory and insigne, the Foundation aims to encourage acceptance of

the Joint Committee standards. The laboratory will furnish experimental evidence to evaluate equipment. The seal will identify equipment that equals or surpasses basic standards. Such a seal of itself does not assure the sanitary use of equipment. Its significance depends upon the reputation of the forces behind it. This is true of every symbol, from a common trade mark to the American flag.

As the activity of the National Sanitation Foundation laboratory expands, its seal will gain in significance. But the value of such a seal fundamentally will be reflected by its use by industry and by regulatory agencies. No system of laboratory examinations, legal penalties, or other enforcement techniques, however careful, is as effective as free agreements honored among mutually contracting parties.

Private institutions like the Foundation are especially free to encourage experiment with public health methods, including educational activities. They can undertake activities which meet deeply felt needs of community action programs in public health. The potential educational power of such cooperative organizations is one of their most promising aspects.

There is still, after a century of public health work, a serious need for community campaigns of health education which a public or professional agency cannot ordinarily satisfy. A governmental agency is obliged to be conservative in education activity, in deference to the principle that government is the servant of the people and not their schoolmaster. Professional organizations by their nature are more concerned with the special interests of their members than with general needs of the public.

Private organizations, however, if sufficiently endowed, can encourage a bold and experimental approach in educational services.

If there is an element of rivalry and competition in such educational programs, all the better. If the community is to have its money's worth from health education, citizens ought to enjoy an opportunity to compare the relative performances of different kinds of organizations and institutions. In competition of this kind, it is unlikely that the public will be the loser.

The major value of these new institutions,

however, is not that they may be more zealous, dynamic, and enterprising than professional or official bodies. These virtues are welcome, but they are but a supplement to their prime function—to provide a common forum and instrument for allied interests in the field of sanitation. Should they contribute further to stimulating comprehensive sanitation activities (6), helping the social forces of the Nation to put a new face and a new heart into American neighborhoods, they will more than have fulfilled their promise.

Summary

In summary, there has been a need for institutions which will accelerate agreement and action on progressive sanitation measures among the many allied interests in this field. The organizations formed by these allied interests have already encouraged cooperative action among governmental, professional, and industrial organizations. They have helped to achieve a uniform approach to sanitation design and construction of equipment. As they de-

velop, they can help also to satisfy some of the needs for health education and research. The competitive aspects of this situation should be healthful in every sense of the word.

Dining Car Sanitation Award

The Erie Railroad has been awarded a special citation by the Public Health Service for being the first major line whose dining cars have all been awarded the Certificate of Sanitation under the cooperative inspection program of the railroads and the Public Health Service.

To achieve the Certificate of Sanitation a dining car must receive a rating of at least 95 percent by a Public Health Service dining-car inspector. The inspection is based on a check of 128 separate items involving both basic construction of the car, particularly the kitchen and the pantry, and maintenance of sanitation. The standards for dining-car sanitation were established several years ago by the Public Health Service in cooperation with representatives of the railroads.

The citation was presented June 3 at a special ceremony in Jersey City.

The Value of Good Service Statistics In a Modern Health Department

By EVELYN FLOOK

WHAT ARE service statistics? Why are they needed? How are they produced, and how should they be used? What is their value to a health officer or to a health program director?

Every public health worker is apt to define service statistics differently and according to his own particular experience and interest. A useful definition is this:

"Service statistics in public health are numerical measurements of services rendered to individuals and to the community through public health programs."

That definition, developed by the Working Group on Service Statistics of the Public Health Conference on Records and Statistics, represents a composite formulation of operating statisticians associated with local, State, and Federal health agencies (1, 2).

Service to People

Perhaps the most important concept concerning service statistics is that they should reflect

Miss Flook is public health adviser in the Division of State Grants of the Bureau of State Services, Public Health Service. This paper is based on a talk before the statistical and clerical section of the Southern Branch, American Public Health Association, at the Branch's 22d annual meeting in Atlanta on April 23, 1953.

For the past 2 years, Miss Flook has been chairman of the Working Group on Service Statistics of the Public Health Conference on Records and Statistics.

service to people and not attempt merely to measure volume of activity of the health department staff. There is a fine distinction between the traditional activity counts—enumerations of nursing and clinic visits for various purposes or of sanitary inspections of different types of establishments—and the kind of statistics which focuses attention on numbers of persons served and types and amount of service received. With the traditional counts, quantitative evidence is being accumulated to describe how each public health worker spends his time—how much effort is being expended for each separate program. With the latter type of statistics, information is being collected on the results of that effort.

"Measurement of results" then, is the key to what we want to achieve with service statistics. The term "service yield indices" is an apt phrase. Just as a farmer finds it necessary, if he is to know whether he is operating at a gain or loss, to reckon the number of bushels of wheat or bales of cotton he gets per acre in return for the labor and expense of production, so the public health worker must calculate the service being rendered to the community in relation to the need for service.

Discussing operational statistics from the viewpoint of a local health administrator, Mattison (3) notes that "it is remarkable, with a few outstanding exceptions, how little really useful information has been available to us health officers in the past in the way of quantitative relationships between morbidity, mortality, population characteristics, and public health services."

Service statistics, to be meaningful, must be related to such baseline data as population by age groups; morbidity, natality, and mortality information; information concerning the health needs of special groups; information about health facilities, services, and personnel available under public, voluntary, and private auspices; information concerning housing, sanitation, and the nutritional and general economic status of the community; and information reflecting expenditures. True measurements of accomplishment cannot be arrived at by counting units of service alone. Quantitative relationships must be established between the services rendered and the health problems to be solved.

In reviewing data for administrative planning, Mattison also points out that unfortunately the one thing usually missing from the kinds of data usually collected in a local health department "was any cross relationship of services to population served or even associations of differing population patterns with differing specific mortality or case rates. Nor are the sanitation inspection figures usually related to the total need in terms of numbers of institutions of the various types inspected and results attained in securing abatement of violations for any particular inspection unit" (3).

For Program Guidance

Service statistics are needed as guides for the three main segments of health department administration: program planning, program operation, and program evaluation. The science of public health has developed to the point where it must be selective in its undertakings if it is to move forward consistently toward a goal of "positive public health" for all.

Intelligent evaluation, stemming from objective data, is the touchstone of progress for any health department. If the public health dollar is to accomplish the maximum good, it must be spent in the area of maximum need. Our efforts must be addressed to the most serious health problems, program emphasis must be shifted as the problems change, and, in each instance, methods used must be those producing the best results. To obtain assurance, there

must be continuous program evaluation and re-direction of planning when necessary.

Like other problems in contemporary society, public health problems are in a state of constant flux. The character of health needs has changed along with changes in the social and physical environment and improvements in the standard of living. Fifty years ago when the local public health movement began, many parts of this country were faced with epidemics of serious proportions; with outbreaks of such infectious diseases as diphtheria, smallpox, typhoid fever, and malaria; and with high maternal and infant death rates. Public health workers naturally turned to preventing and controlling epidemics, to curbing the infectious diseases, to insuring a clean and wholesome physical environment.

Over the years, however, the character of public health problems has undergone considerable change. While many communicable diseases have been virtually conquered, the volume of chronic and long-term illnesses continues to grow. The health of mothers and children has undergone constant improvement, but we are only beginning to look at the needs of the aging group in the population. Various safeguards have been developed to protect the physical environment, but the increased use of chemicals and other new substances creates hazards unknown or unappreciated in the past and in many instances still not fully comprehended.

Good service statistics help keep a modern health department modern. They help define the health problems of the community at any point in time. They help measure both the extent of a program and its effectiveness in relation to the problems. By thus appraising programs and charting paths of action, they furnish a basis for future program planning. If properly used, they can be a sensitive barometer of need for more or less attention to any given problem, in any particular location, at any special time or for change in methods or techniques. Just as it is wasteful to continue the performance of outmoded public health practices long after the need for them has passed, so also is it disastrous to discontinue prematurely the fight against a public health problem. Eternal vigilance is essential if gains already

made are to be maintained. Only then can new problems be attacked in orderly process.

And what place do good service statistics have in program operation?

Service statistics should, for the most part, be a byproduct of administrative operation of a program. Maintenance of records, and compilation and interpretation of statistics, should be an integral part of program management. Only a few examples of the many uses of service statistics for program management need be mentioned. Reports of clinic attendance might suggest changes in clinic policy, dates, hours, or location in order to adjust services to needs. Such reports may also be considered as leads to the effectiveness of home nursing visits. Total clinic visits related to physician time can be used to evaluate clinic policies. Broken appointments and failures to respond to recommendations are signals for closer scrutiny of operations to discover "soft spots." Summaries of program activities provide a basis for determining personnel needs and for justifying specific types of expenditures.

For the guidance of program operation, the value of periodic analysis of individual case records should not be overlooked. Case records of individuals served by the health department constitute the best source of service data in a well-conducted department. A comparison of performance as revealed in the record against the department's stated plan and criteria of service permits a critical appraisal of the adequacy of actual performance. It is an excellent tool for supervision.

Compilation of service statistics by periodic case record analysis is less expensive and more valuable than the accumulation of a vast quantity of uninterpreted data, which is still a wide practice among public health agencies. To illustrate:

If all known tuberculosis cases are analyzed once a year to determine how many are patients in the hospital, how many are patients at home, the sputum status of those at home, and the number of tuberculous individuals at home who were last examined more than a year before, attention is being focused on a specific problem and the health department's success, or lack of it, in keeping individuals under supervision.

If, in addition, records of all new tuberculosis cases are examined to determine the stage and age of the case, attention will be drawn to the success of case finding.

A summary of this type of data provides appropriating bodies with a better understanding of the health department program and its needs than does the traditional count of visits, inspections, admissions to broad categories of service, and so forth. In order to demonstrate the advantages of related statistics, it may be necessary to furnish both types during the transition period, although that is questionable. Public officials ask for evidence of health department effort in terms of gross volume because that is the variety of information they have become accustomed to receiving. There is nothing mysterious about the more searching kind of statistical information, and there is no real reason why it could not be substituted for straight, unrelated counts.

Good Service Statistics

What characterizes good service statistics?

First, they must be developed in line with clearly defined program objectives. Sound statistics do not just happen. They are based upon previous determination of the precise kind of data needed for each purpose. Each item of information must be significant for the specific purpose it is designed to serve, and the exact purposes to be served have meaning only in relation to what a program is designed to accomplish.

Second, the information accumulated must be valid and readily available. The units of measurement to be used should be determined jointly by the program directors and the statisticians prior to beginning their collection. Such program personnel as physicians, nurses, nutritionists, social workers, health educators, and statisticians should take part in developing plans for the collection of information needed.

Third, good service statistics should be limited to a scope and volume commensurate with reasonable cost, time, and effort of production. Collection of statistics—no matter how good—as an end in itself should be discouraged.

Let us consider a few concrete examples of good and not-so-good service statistics. Mere

counts of activities, without being related to the need or demand for a service, add little to knowledge of the problem or to program planning. For instance, in regard to immunization, it is the level of immunization in the community that is important. Counting the number of immunizations given at specified places falls far short of providing that essential knowledge. But the more valuable service statistics—those measuring services to individuals—are based on counts of the patient load according to: whatever breakdowns (age, sex, race, residence, and so forth) are significant; and the categories and amount of service received, grouped so that service is related to the particular health problem. As another example, more useful information on maternity services can be obtained by relating antepartum, delivery, and postpartum services to the women who were delivered of babies within a specified period of time than by using unrelated counts of the three types of services.

Shown in the box below is a pattern of service statistics for a tuberculosis screening activity which relates activity to the problem, specifically, the number of persons screened to the population concerned. Visualize these statistics on a descending scale, as illustrated, with each indented entry a fraction of the preceding one.

By such relationship of information, the number for whom rechecks were recommended, the percentage of tested individuals who had evidence of tuberculosis and the number of diagnoses confirmed by private physicians provide a

guide to the validity of the test. The number for whom rechecks were recommended and completed is an indication of the adequacy of followup. Reporting on this basis makes possible good comparison of services between various reporting areas and between selected periods of time.

Use of Information

Even though we accept in principle the importance of having good service statistics in a modern health department and apply sound criteria for accumulating meaningful statistics, tabulation of such data does not in itself provide for its optimum utilization. To be of real value, information should not only be useful, it must be actually used. We are fortunate in having available a few guide lines to use of statistical data as well as to production.

The periodic review of individual case records has already been mentioned. Case record analysis should be made regularly, but it should be limited to stated times: quarterly, semiannually, or annually. This reduces handling and permits more thorough analysis of each service.

Perhaps the most orthodox method of presenting statistical data is in the form of summary tables or reports. Reports should be prepared only to fulfill definite purposes. The frequency with which they are prepared must be determined locally, depending on the use to be made of the information assembled. Caution is urged against more frequent tabulations than are justified by actual use. Compilation of service statistics on a calendar-year basis is usually most satisfactory for comparison with baseline data. Where statistics are used for fiscal purposes, compilation on a fiscal-year basis should supplement, but not substitute for, calendar-year data. Narrative analyses and graphic presentations are important adjuncts to statistical tables in the interpretation of numerical measurements of service. Such interpretation includes correlation with baseline data, with expressions of needs for services, and with program objectives.

More extensive use should be made of special, short-term studies, aimed at answering specific questions, as a device for reducing the number and complexity of routine reports. Routine re-

Pattern of Service Statistics

ports should concentrate on minimum essentials for reflecting program activities and should avoid overrefinement of data. Special studies permit more critical analysis of a selected segment of a program for a limited period of time and do not overburden the staff indefinitely with a vast amount of details.

Some types of service statistics which might be obtained through special studies are: determination of levels of immunizations; evaluation of specific new services or program techniques; changes in behavior resulting from health department activity; determination of reasons for lapses in attendance at clinics or for failures to complete immunizations; comparison of effectiveness of individual interviews versus group conferences; and time and cost studies.

Summary

Several points may be suggested, then, for the guidance of public health workers concerned with numerical measurement of public health services:

Service statistics should reflect service to people. They should not attempt merely to enumerate volume of activity of the health department staff.

Service statistics are needed by modern health departments for program planning, program operation, and program evaluation.

Full value cannot be derived from service statistics unless they are related to baseline data. Organized methods are needed for bringing together the several groups of data so that quantitative relationships can be established between

the services rendered and the health problems to be solved. The acid test of service statistics is whether they portray results of public health effort.

Good service statistics must be developed in accordance with clearly defined program objectives. In scope and volume, they should be limited in terms of cost, time, and effort of production commensurate with the need they must meet and the uses to which they are put.

Frequently, preparation of recurrent statistical reports can be simplified by substituting special studies for routine collection of complex mass data.

Health Education via Television

By JOSEPH GORDON

WHILE THE CONTROVERSY over education via television continues in the press, in periodicals, in educational journals, and around many a conference table, a modest number of TV stations working with medical and other health agencies have unpretentiously launched regularly scheduled health video programs. Most of these programs have been dedicated to promoting better health habits and attitudes in the individual as well as in the community which the TV station and the health agency serve.

How well these objectives are being met remains to be evaluated, but favorable audience response to current programs is a good indication that health education over TV fills a definite need for the citizen.

In 1951, in an effort to evaluate the status of health education via television on a nationwide basis, some 110 questionnaires were sent by the Baltimore City Health Department to all active TV stations over the country. Of the 64 questionnaires returned, 28 television stations which were not carrying regular public health education programs indicated they would carry such a program provided it were sponsored by a health agency. Sixteen TV outlets replied

that they then carried sporadic health telecasts throughout the year in conjunction with special health drives; but only seven stations were producing regular periodic health programs. It is surprising that, with this interest evidenced by TV stations, so few health agencies have grasped the opportunity to utilize this new and effective dimension for health education.

Why are many health departments, medical societies, and other health agencies not taking advantage of the opportunities afforded by TV for health education?

Is it because of a lack of aggressiveness on their part?

Is it because of their skeptical attitude toward the value of television as a medium of education?

Is it an unfamiliarity with a technique which resembles that of motion-picture production?

Or is it essentially because the costs of production are believed to be excessive?

Whatever the answer, a delineation of the Baltimore City Health Department's experience in television is offered here with the hope that it may help to refute some of these unwarranted conjectures and that it will encourage those who wish to utilize television as an aid to promoting better health.

Background

Baltimore's program (1-3), a 15-minute weekly series bearing the title "Your Family Doctor" rests on a triangular foundation. It is jointly sponsored by the Baltimore City Health Department, the Medical and Chirurgical Faculty of Maryland (the State medical society), and WMAR-TV, a local television station. This triple bond gives the television series its

Joseph Gordon has been director of the bureau of health information, Baltimore City Health Department, since 1950. From 1947-50, he was with the Baltimore County Department of Education at Towson, Md. A graduate of the University of Rhode Island, he attended Columbia and Johns Hopkins Universities for graduate work in education and public health. He was formerly head of the science department at the Stonington (Conn.) High School.

strength. The city health department is responsible for planning and programing. The medical society makes available consultants who act as advisers or guests on the program. And the TV station donates as a public service the air time and the technical personnel for telecasting.

"Your Family Doctor," the weekly program, was inaugurated on December 15, 1948. There have been only three cancellations since then, and these were due to election commitments.

Participating in this first telecast were the mayor of Baltimore, the president of the Medical and Chirurgical Faculty of Maryland, the chairman of the council of the faculty, the city health commissioner, "Dr. John Worthington" played at that time by the former director of the bureau of health information in the city health department, and Dr. Worthington's "office nurse," played by a public health nurse.

The program opened with the mayor's special remarks on its aim and his acknowledgment of the efforts of the physicians of Maryland and the television station in making the TV health series possible. The president of the State medical society spoke about the importance of the family doctor in protecting and promoting personal health and the role he plays as teacher and family counselor. The commissioner of health described the kind of telecast to be presented each week. The "doctor" and his "nurse" gave a short dramatic presentation in the setting of the "doctor's office."

Purpose and Authenticity

"Your Family Doctor" is designed to promote interest in and understanding of personal and community health. Its prime functions are to increase the public's knowledge of the basic practices for keeping well; to encourage consultation with the individual's family doctor when there is any doubt about illness; to present public health problems and their local application to the community; and to inform and familiarize the public with the activities of the local health department. In essence, "Your Family Doctor," through the medium of "Dr. Worthington," attempts to join, with skill, education and entertainment in the encouragement of good healthful living.

Overall responsibility and supervision of program production (4, 5) rests with the director of the bureau of health information in the city health department. Programs are selected on the basis of timeliness and need by a television committee composed of the commissioner of health, the assistant commissioner of health, key city health department administrators, the scriptwriter, the studio producer-director, and the director of the bureau of health information, who acts as chairman of the committee. Besides the selection of program topics, the committee designates well-known authorities as specialist advisers for each program.

The following procedure insures the authenticity and accuracy of each program:

A preliminary conference is held to decide on the information to be presented. The method of presentation is discussed and decided on. The conference is attended by the specialist adviser, the scriptwriter, the studio producer-director, and the director of the bureau of health information.

After the preliminary conference, a script is prepared and submitted to the director of the bureau of health information for his approval.

The director of the bureau of health information and the specialist adviser critically examine the script. They check on the accuracy of each statement and for the possible omission of essential facts.

Final approval is given, and copies of the script are prepared by the bureau of health information for distribution to the studio and the cast. The participants memorize their lines, in this way avoiding the possibility of misrepresentation.

Cast and Properties

The part of Dr. John Worthington, the central character of each weekly presentation, is portrayed by a staff member of the city health department who has had professional acting experience. "Dr. John Worthington" was chosen as the name of "Your Family Doctor" because he was one of Baltimore's first health officers, appointed during the yellow fever episode of 1792.

Other members of the cast are recruited from the television studio and from Baltimore the-

atrical groups. Persons with dramatic experience are preferred as actors, but often staff members of the city health department volunteer their services. All participants contribute their talents without charge.

Properties are assembled by the television studio and the bureau of health information. Property items (props) have been contributed to the programs by the Johns Hopkins University and Hospital; the University of Maryland Medical School and Hospital; the Baltimore city and county departments of education; the Public Health Service and the Food and Drug Administration of the Department of Health, Education, and Welfare; the Armed Forces Institute of Pathology in Washington, D. C.; and numerous voluntary health agencies.

Cost of Production

Scriptwriting is the main item of expenditure. Scripts are written by a studio staff member for a fee of \$20 for each script. Having a studio member write the scripts has been a workable and satisfactory arrangement since the scriptwriter is then familiar with television techniques and the available studio property items.

During 1951 and 1952 an additional outlay of \$10 a program was made for the services of a professional actor who portrayed "the family doctor." The writing and acting expenses for this period totaled \$1,560 per year. An additional \$200 a year is estimated for the production of props—photographs, charts, diagrams, drawings, postage, transportation, and incidentals. Stencils and paper for script reproduction are estimated at \$100 a year. The total annual cost to the health department, excluding the services of staff members of the bureau of health information, was \$1,860 a year. This sum, in the light of approximate expenditures for other health educational media, films, exhibits, leaflets, and posters, is not excessive: Rather, it is a small sum when it is compared with the costs of commercially sponsored programs and when one considers that the health message reaches thousands of persons of all ages more easily and personally than any other medium of mass communication. The outlay can be greatly minimized by writing the pro-

gram within the health department and by drawing on a staff member of the department for the regular weekly appearances.

The Telecast Format

Each health telecast follows a standard format which on occasion is varied to meet the needs of the program. In general, the following time sequence is typical of the standard program format:

Opening scene (30 seconds). A "live" or filmed dramatic sequence to catch audience attention.

Standard titles (30 seconds). Superimposed over opening scene whenever appropriate.

Body of program (10 to 12 minutes). This may take any form: a health drama, a series of experiments, an illustrated lecture, a film, or any combination of these.

Guest specialist (usually 2 to 5 minutes, but time varies according to subject). Outstanding personalities are frequently invited to appear on "Your Family Doctor" in order to highlight the program and lend added authenticity. Since the program is sponsored by the city health department and the State medical society as part of their health education program, their teamwork makes it possible to obtain such personalities. Guests in the past have included members of the Johns Hopkins University and Hospital, the University of Maryland and the University Hospital, the city department of education, the voluntary health agencies, the American Red Cross, the State and city medical societies, the health department, and other municipal agencies.

Ending. Each program ends with "Learn to do your part in the prevention of disease."

Range of Subjects

A summation of the health subjects covered in the series is given in the accompanying table. Included under the communicable disease control classification are 9 programs on tuberculosis and 4 on respiratory ills. Other programs in this category were concerned with poliomyelitis, diphtheria, typhoid fever, measles, smallpox, ringworm, Rocky Mountain spotted fever, and hospital services and research in communicable diseases. Five programs on sanitary

Range of 230 subjects covered in weekly telecasts by broad classifications, Dec. 15, 1948–May 30, 1953

meat and milk inspection services are included in the food and nutrition group. Accident prevention covers home accidents, vacation hazards, and water safety. Special health department services include telecasts describing laboratory services, vital statistics, and special health district activities. Programs in the miscellaneous group were devoted to the work of the State medical society; the American Red Cross blood drive; the recruitment of student nurses; the activities of the Instructive Visiting Nurse Association; the work of the city's chief medical examiner; several community health drives; and a variety of ills including cerebral hemorrhage, sinusitis, allergies, appendicitis, and multiple sclerosis.

Audience Response

Prior to, and during 1950, according to WMAR-TV survey records of the television audience of metropolitan Baltimore (popula-

tion, 1.3 million), the number of viewers each week of "Your Family Doctor" was estimated at no more than 20,000 individuals. Early in 1951, this number had increased to approximately 40,000 persons. By October 1951, the viewing audience had grown to an estimated 75,000. In November 1951, a rating survey revealed that more than 85,000 people were attracted to the program. Early 1952 ratings indicated a stabilization of this figure. After a brief summer decline, an October 1952 rating gave the program an audience of 125,000 persons, exceeding that of many commercially sponsored TV entertainment programs in Baltimore.

A measure of the program's effectiveness may be derived from an abundant correspondence stimulated mainly by offering free literature on health subjects. Our correspondents speak of "Your Family Doctor" as being an invaluable contribution to the community health of Baltimore, of their friends' favorable remarks, of the aid the program gave in putting over an important bond issue for a public hospital; others frequently ask for additional information on the topic of the week.

Summary

Baltimore's program is one in which health information and education emanate from the family doctor as he deals with his patients and their diseases. Not only is the family doctor interested in promoting individual health, he is also concerned with improving the health of the community. In accomplishing these aims, "Your Family Doctor" utilizes every available source of medical material and every practical audiovisual technique. In so doing, it has enlisted the cooperation of every important health agency in Baltimore, both official and nonofficial. That these efforts are well expended is evidenced by the increasing number of viewers.

Can public health agencies afford not to consider using TV as a medium for disseminating health information to the public? Television is an additional tool in the hands of the health educator. The skill and care with which he uses it can contribute to the better health of the individual and the community in which he lives.

Training Courses in Venereal Disease Control

The Public Health Service Venereal Disease Research Laboratory at Chamblee, Ga., has scheduled refresher training courses to be given during fiscal 1954.

Two-week courses in the serology of syphilis will be given on the following dates:

1953	1954
Aug. 17-28	Jan. 11-22
Sept. 14-25	Feb. 8-19
Oct. 5-16	Mar. 8-19
Oct. 26-Nov. 6	Apr. 5-16
Dec. 7-18	May 3-14

Other courses scheduled are:

Oct. 5-16, 1953: Management and control of syphilis serology by the regional laboratory (for assistant laboratory directors and senior laboratory staff members—includes review of interlaboratory training programs, regional laboratory evaluation studies, laboratory inspection procedures, demonstration of antigen check testing, and control serum preparation.)

Oct. 19-23, 1953: Laboratory diagnosis of venereal disease (for public health physicians, laboratory directors and assistant directors).

Nov. 9-20, 1953: Preparation and standardization of cardiolipin antigens used in serologic tests for syphilis (also to be given May 17-28, 1954).

Correspondence on these courses should be sent to: Director, Venereal Disease Research Laboratory, P. O. Box 185, Chamblee, Ga.

Diabetes Mortality by State for 1950

In 1950, the death rate from diabetes in the United States was 16.2 per 100,000 population. Final figures by State, recently released by the National Office of Vital Statistics, show considerable variation in this death rate from State to State. The diabetes death rate was lowest in New Mexico, where a rate of 5.6 per 100,000 was recorded, and highest in Rhode Island, which had a rate of 35.9 per 100,000. Seven States, New Mexico, Arizona, California, Alabama, Arkansas, Tennessee, and North Caro-

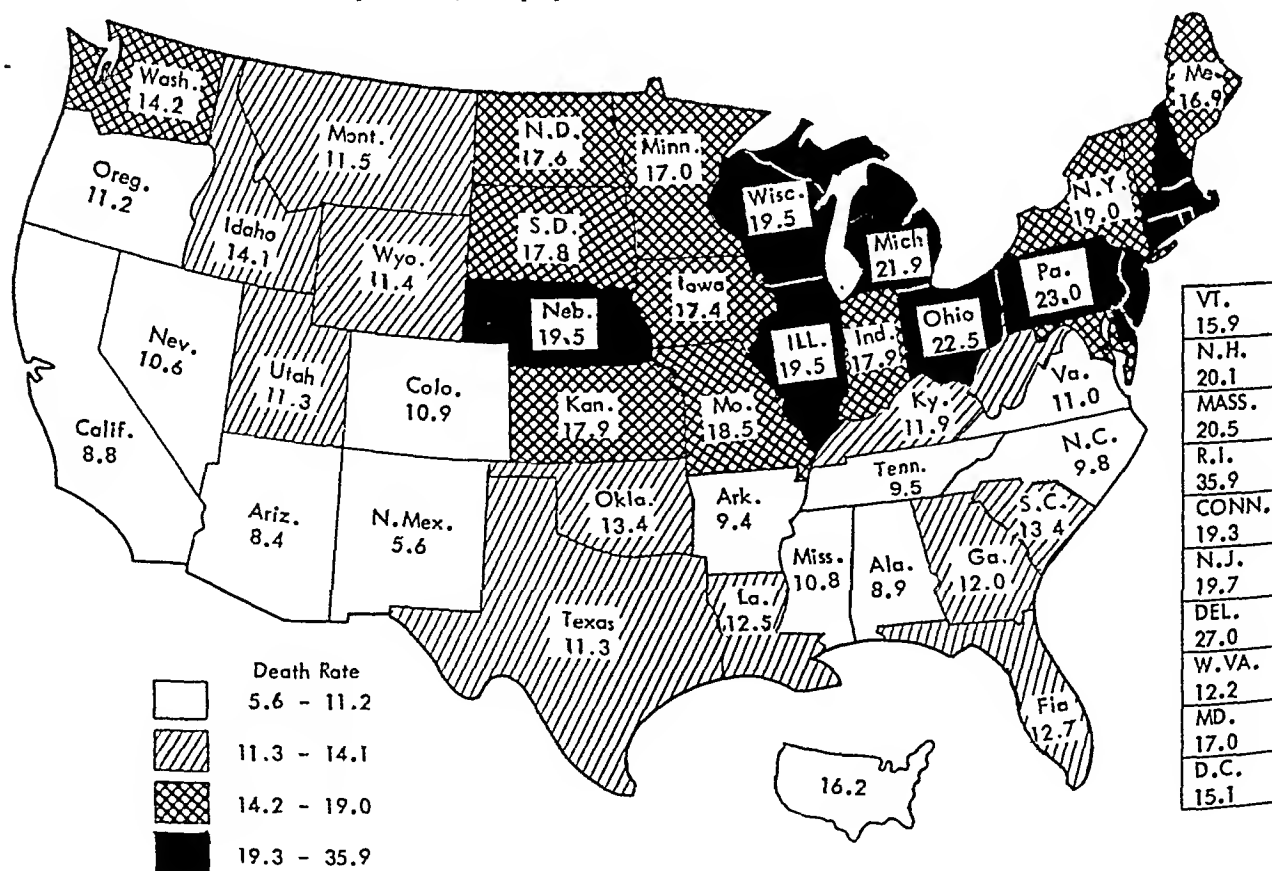

lina, had less than 10 deaths per 100,000, while rates greater than 20 per 100,000 were recorded for New Hampshire, Massachusetts, Michigan, Ohio, Pennsylvania, Delaware, and Rhode Island.

An array of the States by their 1950 diabetes death rate and division by quartiles shows a definite pattern on the map. Generally, the southern and western States have low death rates, and the northeastern and north central States have high rates.

Many factors undoubtedly influence the variation in the diabetes death rate among States and among regions. The differences may be due to real variations in the death rates for diabetes

This report was prepared by the Division of Chronic Disease and Tuberculosis, Public Health Service.

Diabetes deaths per 100,000 population in the continental United States, 1950

because of varying case fatality rates or varying prevalence rates. They are in part reflections of differences in the social, economic, and cultural patterns of the population groups, and differences in the availability of medical facilities and in methods of reporting causes of death.

Another important factor to be considered in comparing the death rates among the States is

the age, race, and sex composition of their populations. States having a high proportion of older people would be expected to have a high death rate for this disease. The rate among the nonwhite population (14.4 per 100,000 population) was slightly lower than that for the white (16.4); while for females, the rate (19.9) was considerably higher than for males (12.5).

Environmental Health Training Courses

Twenty-three training courses will be conducted during fiscal 1954 by the Environmental Health Center of the Public Health Service at Cincinnati, Ohio—15 in the various aspects of sanitation and 8 in radiological health.

These short courses are given for professional personnel from State and local health departments, water pollution control agencies, the Public Health Service, other governmental units, educational institutions, and industries cooperating with these agencies in environmental sanitation programs.

The advanced sanitation courses planned during 1953 and 1954 are:

Sept. 17-18: Fluoride analysis.
Sept. 23-25: Seminar on individual household sewage disposal systems.
Oct. 12-16: Membrane filter in bacteriological analysis of water.
Nov. 2-6: Nuisance organisms in water supplies.
Nov. 30-Dec. 11: For chemists—water pollution investigations.
Jan. 11-15: Bacteriological examination of water.
Jan. 18-22: Bacteriological examination of milk and dairy products.
Jan. 25-29: Food sanitation training.
Feb. 16-18: Phenol determination.
March 8-19: For sanitary engineers—water pollution abatement programs.
April 7-9: Bioassay of industrial wastes.
May 3-7: Membrane filter in bacteriological analysis of water.
May 19-21: Analyses of metals in industrial wastes.
June 8-11: For aquatic biologists—water pollution control.
Emergency sanitation training (will be scheduled if requests are sufficient).

In radiological health training, the basic course, which stresses basic radiation physics and survey techniques, will be presented:

Oct. 5-16, 1953	January 11-22, 1954	May 3-14, 1954
-----------------	---------------------	----------------

The intermediate course, emphasizing laboratory assay of radio elements and X-ray survey techniques, will be given:

Oct. 19-30, 1953	Jan. 25-Feb. 5, 1954	May 17-28, 1954
------------------	----------------------	-----------------

An advanced course for professional personnel concerned in particular with occupational health problems will be presented:

Feb. 8-19, 1954

The date of a short course for water works personnel will be announced later.

A bulletin describing the courses and giving further details is available upon request from the Officer in Charge, Environmental Health Center, Public Health Service, U. S. Department of Health, Education, and Welfare, Cincinnati, Ohio.

Rat-Resistant Construction Materials

In a study to determine the resistance of construction materials to penetration by rats, panels of construction materials, including aluminum, were exposed to gnawing by wild roof rats. In specially designed cages, single sheets of test materials were used as barriers between the rats and food and water. The rats, kept on reduced rations, attacked the panels in an effort to reach the bait.

The study showed that rats require a gnawing edge to make any appreciable progress in penetrating materials. They can develop such an edge on soft materials, but with harder materials they require a construction joint or a fracture as a point of attack. All but a few test materials were penetrated when a gnawing edge was exposed.

Without gnawing edges, some materials were penetrated in 1 to 8 nights. Others were penetrated in about the same length of time, but required a gnawing edge. Some of the harder materials and heavier-gauge aluminum alloys required 34 to 126 nights' exposure with a gnawing edge. The hardest grades of asbestos cement and metal base plates of sheet iron withstood up to 122 nights of exposure without penetration or serious damage.

It was concluded that none of the materials, by themselves, were absolutely ratproof, but that composition building materials in the harder grades of asbestos cement products could be made relatively ratproof by protecting construction joints or other raw edges and by protecting the material itself in easily accessible areas.

Aluminum alloys were quite easily penetrated except for the harder tempers in the thicker sheets. Aluminum sheet material used as construction facing should be protected at all raw edges, preferably by sheet iron. Although aluminum alloys shaped as door channels with-

Public Health

MONOGRAPH

No. 11

The accompanying summary covers the principal findings presented in Public Health Monograph No. 11, published concurrently with this issue of Public Health Reports. The authors are members of the staffs of the Communicable Disease Center and the Division of Water Pollution Control (Southeast Drainage Basin), Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Tarzwell, C. M., Stenborg, R. L., Nicholson, H. P., and Lynn, W. D.: The resistance of construction materials to penetration by rats. Public Health Monograph No. 11 (Public Health Service Publication No. 277). U. S. Government Printing Office, Washington, 1953. Price 20 cents.

stood gnawing exposure considerably longer than the same alloys exposed as plain sheets, they are not considered suitable replacements for galvanized sheet iron as protective door channels.

Federal Care and Treatment Of Insane Prisoners

The power of the Federal Government to provide for the detention and care of "insane" persons in its custody was narrowly construed in a recent opinion of the Court of Appeals for the 10th Circuit—*Wells v. Attorney General*, 201 Fed. (2) 556 (1953).

The Court held that the Congress has power to provide proper care and treatment for persons who become temporarily insane while in the custody of the United States awaiting trial on criminal charges, and for Federal prisoners who become mentally incompetent during the term of their imprisonment after conviction. However, the Court also held that the Federal Government has neither constitutional nor inherent power to enter the general field of lunacy and to assume to act as *parens patriae* for the permanently insane. Section 4246 of the Federal Code of Criminal Procedures was accordingly interpreted as applying only to the temporarily insane.

Accused of a Federal offense, the petitioner in the case had been found to be mentally incompetent after a period of observation at the Medical Center for Federal Prisoners, Springfield, Mo. Pursuant to statute, he was com-

mitted to the custody of the United States Attorney General until he should become mentally competent to stand trial or until the charge against him should be disposed of according to law. While in jail awaiting transfer to an institution, he petitioned for a writ of habeas corpus challenging the validity of his commitment. The District Court denied his petition. The Court of Appeals remanded the case with directions for a hearing and finding as to whether the petitioner's mental incompetency was temporary or permanent.

A dissenting opinion in the case took the view that once the Federal Government has acquired jurisdiction over mental incompetents, as in an arrest for or conviction of a Federal offense, its duty is to protect and care for them whether they are temporarily or permanently incompetent; also that the manner in which the duty is to be discharged is to be determined by the Federal Government.

This note has been prepared by the Public Health Division, Office of the General Counsel, Department of Health, Education, and Welfare.

Public Health Service Publications Issued During 1952

A listing of all Public Health Service publications released during the calendar year 1952 is now available upon request to the Public Inquiries Branch, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington 25, D. C. Entries are classified by general subject matter. Periodicals issued during the year are also listed.

Health of Workers in Chromate Producing Industry

Public Health Service Publication No. 192. 1953. 131 pages; tables, charts. 50 cents.

An investigation made by the Public Health Service relating to the incidence of carcinoma among workers in chromate production substantiates this problem. The detailed report of findings includes the origin of the study, which was requested by the chromate industry, an abstract-summary, discussion and recommendations, and an appendix giving chemical analyses methods of air-borne particulate materials.

Factors which might influence the abnormally high rate of bronchiogenic cancer among these workers are reported in the correlation of clinical and environmental findings. Other derivatives of chromate ore than those incriminated by previous investigators are considered.

Recommendations are that established industrial hygiene engineering principles be applied to all chromate plants; that workers in the chromate industry for 5 or more years be examined by X-ray every 3 months and have followup clinical examinations by local health departments; and that the morbidity and mortality experience studies among chromate workers be continued.

Public Sewage Treatment Plant Construction, 1952

Public Health Service Publication No. 291. 1953. 18 pages; tables.

The Nation's progress in reducing the pollution of its water resources through construction of municipal sewage treatment plants is summarized in this report, which reveals that a total of 515 communities in the United States awarded contracts for this type of construction in 1952. The total expenditure involved, \$137 million, is less than that expended

for any year since 1948 and falls short of the long-term average of \$141 million for the period 1915-50.

In addition to this information the report contains tables showing contract awards by drainage basin, population served, type of construction, and cost. Data are given on present and estimated future water use, and population and industrial growth. The tables also show contract awards by amount spent for the years 1948 to 1952 and the expenditures for various types of public utility construction are compared.

The accompanying text discusses the data in terms of the importance of pollution control for health and economic reasons and explains why communities are lagging in municipal sewage-treatment plant construction. A complete list of the 1952 contract awards is given in the appendix.

The Dietitian in the Hospitals of the Public Health Service

Public Health Service Publication No. 254. 1953. 26 pages; illustrated. 15 cents.

One of several publications on careers in the Public Health Service, this small booklet describes the duties and responsibilities of the dietitian in Public Health Service hospitals.

It points out that in addition to supplying the nutritional needs of the patients, the dietitian serves as a member of the professional medical team, working closely with the physicians and dentists on research projects and on special studies and experiments with patients requiring therapeutic diet treatment.

The booklet describes the work of the hospital dietary service. The commissioned corps system is explained and the qualifications and requirements for appointment in the corps are covered, as are salary, quarters, and other benefits.

Venereal Disease Clinic Directory

Public Health Service Publication No. 257. Revised 1952. 148 pages. 60 cents.

This directory is published biennially by the Public Health Service's Division of Venereal Disease to provide the latest information on clinics and other facilities available for the diagnosis and treatment of the venereal diseases.

The material included in the recently published 1952 edition has been compiled from information supplied near the end of the calendar year by health departments of the 48 States; the Territories of Alaska, Hawaii, Puerto Rico, and the Virgin Islands; and by the Division of Hospitals of the Public Health Service. The names and addresses of each diagnostic and treatment facility, the days and hours of service, as well as the fee basis for use of each facility are listed.

Summaries of premarital and prenatal laws as they pertain to venereal disease are given for each State and Territory having such laws. In addition, laboratory facilities available in each State are described.

According to the directory, 39 States and 2 Territories have premarital laws requiring blood tests and physical examinations for venereal disease; 42 States and 3 Territories have prenatal laws requiring blood tests for the pregnant woman.

Biological Products

Establishments Licensed for the Preparation and Sale of Viruses, Serums, Toxins and Analogous Products, and the Trivalent Organic Arsenic Compounds.

Public Health Service Publication No. 50. Revised December 1, 1952. 1953. 46 pages. 20 cents.

In accordance with section 351 of the Public Health Service Act regulating the sale of viruses, serums, toxins, or analogous products or arsphenamine in the District of Columbia and in interstate traffic, the

Public Health Service licenses establishments manufacturing these products in the United States and abroad. The granting of a license means that the establishment is inspected regularly as to the technical ability of the responsible personnel and as to sanitary conditions of the premises. It means that the products are manufactured under methods considered to be safe and that the finished product is tested as to safety and purity and compliance with official standards of potency.

This publication lists all establishments holding licenses and the names of the products for which they are licensed. Part II is a list of the various biological products with the license numbers of the establishments producing them, and part III is an alphabetic listing of the manufacturers.

Management of Chancroid, Granuloma Inguinale, and Lymphogranuloma Venereum

Public Health Service Publication No. 255. Revised 1953. By Robert B. Greenblatt. 66 pages; illustrated. 30 cents.

This is the second edition of the publication issued in 1943 as Supplement No. 19 to the *Journal of Venereal Disease Information*. It has been completely rewritten and revised to include the latest methods used in the management of chancroid, granuloma inguinale, and lymphogranuloma venereum since the advent of the antibiotic drugs.

The booklet describes in detail the etiology, incubation period, epidemiology, clinical signs and symptoms, clinical course, diagnosis, and treatment of these venereal diseases. Tables carry information on incidence of the diseases, as well as data on the comparative efficacy of various therapeutic methods. A special section is concerned with differential diagnosis. The bibliography is extensive and offers a comprehensive survey of the literature on the venereal diseases with which it is concerned.

Written by Dr. Greenblatt, an outstanding authority, in collaboration with several of his colleagues, this book is considered a medical reference work on chancroid, granuloma inguinale, and lymphogranuloma venereum.

Clean Water for the South

Public Health Service Publication No. 250. 1953. 6 pages; illustrated. 5 cents.

Clean Water for the Tennessee

Public Health Service Publication No. 271. 1953. 6 pages; illustrated. 5 cents.

Based on the Summary Reports on Water Pollution for the Southeast Drainage Basin and the Tennessee

River Drainage Basin, these publications are two of a series of brief discussions of the 15 technical reports on the water pollution problem in the United States.

Written in nontechnical language and planned with the State pollution control agencies as a stimulus for local action, the leaflets outline in digest form the specific pollution problems in the Southeast Drainage Basin and Tennessee River areas.

The extent of pollution damage as it affects health, industry, and recreation in each section is discussed, and the areas' and communities' contributions to the problem are outlined. Some of the cities which are now taking positive steps to combat water pollution are named as illustrations of present progress, and public support of local action to control one of the most serious threats to the Nation's welfare is strongly urged.

for the general public

Ulcers

Health Information Series No. 71. Public Health Service Publication No. 280. 1953. 1-fold leaflet. 5 cents; \$1.75 per 100.

This health information leaflet discusses what is known about the cause of ulcers and their course of development. The warning signs of ulcers are described, with emphasis on the necessity of prompt diagnosis and early treatment under the supervision of a physician. Various methods of treatment, such as rest, medicine, and diet, are outlined, and the reasons are given for their use.

Care of the Eyes

Health Information Series No. 64. Public Health Service Publication No. 113. Reprinted 1953. 1-fold leaflet. 5 cents; \$1.75 per 100.

In spite of the defense nature has provided to protect the eyes, they can still be damaged by neglect and abuse. This health information

leaflet explains that good care of the eyes begins with infants, through the protection of their eyes from bright lights and the dangers of pointed objects. School-age children should be taught good reading habits and people of all ages should practice cleanliness in the care of their eyes.

The leaflet also advises regular eye examinations by an eye specialist and explains the difference between the oculist or ophthalmologist, optometrist, and optician.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Recruitment Plan

MICHIGAN. Believing that rewarding careers in the field of health, less well known than medicine, dentistry, pharmacy, or nursing, may be overlooked by parents and teachers in counseling students of junior and high school age, professional groups are cooperating in a new recruitment plan.

The Medical Society, the Michigan Health Council, the Hospital Association, and the nursing profession have joined forces in the State to present the advantages of a career as an assistant, or associate, in one of the numerous medical service professions where shortages exist or where shortages are anticipated.

To coincide with the observance of Michigan Hospital Week, the bulletin of the health council announced that the findings of a recent survey of these professions revealed 960 medical service positions then open in the State. The bulletin named the vocational categories where immediate placement could be made. The survey, made by the Michigan Hospital Association, concluded that in 5 years, even if present needs were met, there still would be 1,890 openings for dietitians, laboratory technicians, medical record librarians, and X-ray technicians, among others.

The wide range of opportunities available in the expanding health and medical associate professions are highlighted in a brochure on career planning prepared by the Michigan State Medical Society.

Together with descriptive text and action photographs, the booklet features a comprehensive chart which outlines each of 26 vocations. The vocational outlines include educational requirements, Michigan schools offering instruction, and information sources outside the State, employment conditions, salary ranges, and opportunities for advancement and security.

Regional Legislative Conferences

FLORIDA. Six regional legislative conferences have been held to acquaint State legislators and community groups with the legislative goals of public health agencies. To assure the greatest coverage, the conferences were held in six key cities. Brief descriptions of proposed health legislation and appropriation requests and a listing of legislation in which the various health organizations had especial interest were distributed.

The conferences were guided by the Florida Public Health Association: Its executive committee provided the necessary funds; its legislative committee made the plans. Tentative dates were set in advance. Community leaders were selected as local regional chairmen in each key city.

A copy of the agenda and a list of the participating groups were sent by letter to all county health officers 2 months before the first meeting. The purpose of the conferences was explained, and the proposed dates, the names of the regional chairmen, and the counties included in each of the six regional areas were given. Each health officer was requested to act as conference coordinator for his county and to suggest the names of leading citizens to be invited to

attend. Other notices were sent to all State legislators and to various individuals and groups.

General news stories describing the conference plans were sent to all newspapers in the State 2 weeks before the first meeting. Regional news stories were sent to the papers in the regional area 1 week ahead of each regional conference. These stories quoted the regional chairmen on the importance of the meeting and repeated the time, place, location, and purpose. Two days before the regional meeting, local news stories with local names and local plans were sent to the county health officers for release in the counties within the regional area. Copies of all stories were sent to radio stations in each region, and news commentators were asked to use the information for local broadcasts.

Presenting their program goals before the regional legislative conferences were representative official and voluntary State groups concerned with public health problems. Among these, in addition to the Florida Public Health Association, were the Florida State Board of Health, the Mental Hygiene Association, the State division of the American Cancer Society, the Florida Tuberculosis and Health Association, the Anti-Mosquito Control Association, the Tuberculosis Board, the Children's Commission, the Hospital Association, and the division of vocational rehabilitation of the Department of Education.

Legislators, official and voluntary agencies, and civic groups were well represented. The estimated total attendance at the 6 regional sessions was 900 including 49 members of the Florida legislature. By the questions they asked, members of the audiences demonstrated their real interest in the public health programs and the proposed legislation.

A stylized outline map of the Americas, showing the continents of North and South America. The map is positioned on the left side of the page, with the title text to its right.

Servicio

Ten Years of Operation

of the

Bilateral Health Programs

of the

Institute of Inter-American Affairs

Excerpts from an evaluation survey
by the Public Health Service, 1953

PUBLIC LAW 369 of the 80th Congress provided that the purposes of the Institute of Inter-American Affairs "are to further the general welfare of, and to strengthen friendship and understanding among, the peoples of the American Republics through collaboration with other governments . . . in planning, initiating, assisting, financing, administering, and executing technical programs and projects, especially in the fields of public health, sanitation, agriculture, and education."

This Congressional enactment in itself recognized the contributions to hemispheric security and well-being which had come from the Institute's activities since its creation in 1942 as a corporate entity under authority granted to the then Coordinator of Inter-

American Affairs. During 1952, following upon a suggestion first advanced in 1950 by the Institute, the Public Health Service undertook to evaluate the bilateral health programs which had been developed with our good neighbors during the previous decade.

Public Health Reports publishes in this and succeeding issues excerpts from the findings and conclusions of this survey. The portions have been selected as being of major interest to professional persons in the fields of public health in three respects: first, for their intrinsic factual value as a report of an international technical assistance program; second, as a "case report" of a technical field evaluation of public health practice; and, as a review of current concepts of public health administration.

. . . from the Surgeon General's

FOREWORD

The fifth decade of this century witnessed some extraordinary advances in international collaboration in the field of public health. Although these advances were partly due to the urgencies of World War II, they have continued into this decade. There is reason to think that, when the history of these troubled times is finally written, the careful historian will see in the emergence of the cooperative health programs in Latin America a significant development in the Western Hemisphere's search for higher levels of health and stability.

The translation of an underlying cooperative spirit into effective action through a joint administrative device, the *Servicio*, marks a significant experiment in international cooperation in health. A will to work together has been coupled with a way to work together in the family of nations.

Servicio Principle

The *Servicio*, as an administrative device, has stood out as one of the special and characteristic features of the Institute of Inter-American Affairs program. The president of the Institute in 1951 described *Servicio* as:

" . . . the generic name of the administrative device through which the Institute works with the other American Republics in the execution of technical assistance or basic economic development programs. The Spanish word "*Servicio*" means service; it is also the synonym for Government bureaus in the United States. A cooperative *Servicio* is a bureau or department of a ministry of a Latin American government, such as the Ministry of Agriculture, Public Health, or Education. . . .

"Although a *Servicio* is part of a ministry, it is autonomous in many respects. Its autonomy is derived from the authority vested in the director to determine, with the concurrence of the minister, the administrative procedure to be followed by the *Servicio*. . . . The Latin American Republic is represented by the minister of the cooperating ministry, and the Institute of Inter-American Affairs is represented by the chief of field party. The Insti-

tute sends to the American Republic such technicians as are required and names as the head of the group a chief of field party. The minister and the chief of field party are co-equals in developing the administrative techniques to be followed by the *Servicio*."

The Task of Evaluation

To characterize the *Servicio* is one thing. To attempt to trace and evaluate the operation of the *Servicio* in all its multiphasic detail and significance is quite another.

The Public Health Service's report represents an initial step toward tracing and evaluating the operation of the *Servicio* in inter-American cooperative agreements. The study is the first of its kind, and is, therefore, unique. It was a shared project in which the chiefs of field party and the specialists of the evaluation team worked together in the field and later around a conference table in Washington. Their aim throughout, through the process of give and take in frank discussion, was to reach a consensus on the final report. Although time limitations prevented gathering the ideal amount of survey data, the report as a whole gives a picture of the program and sets out some guideposts. Incomplete as the study may be, it can serve as a springboard for further accomplishment in international cooperation for the advancement of health.

LEONARD A. SCHEELE, M.D.

. . . from the IIAA President's INTRODUCTION

During the decade 1942-52 many factors gave impetus to the widespread development of public health throughout the Americas. In light of the importance of public health promotion on a worldwide basis, it seemed important to make some estimate of the values inherent in the joint programs of the Institute of Inter-American Affairs, and to determine somehow, if at all possible, the particular merits of the techniques used and the value and effectiveness of programs focused, as these were, at certain defined areas of health development. It was considered necessary that the facts at least be placed in the open for others to study.

With these ends in view, the Institute determined upon an evaluation of its accomplishments in health, yes, and its failures. It wished this to be as objective as possible. It therefore suggested to the Public Health Service, which has had wide and varied experience in evaluating programs within the United States, that it undertake this task. The Public Health Service agreed to attempt the job and has produced a report unique in character and charged with solid values. The evaluation has been not a dead analysis, but a creative assessment, a guide for the future.

That such an undertaking was impossible of accomplishment on any quantitative, traditional, statistical basis was evident from the fact that the basic data concerning the underlying problems and the progress made toward their solution were lacking. This lack is indeed one of the outstanding problems in Latin America even today. It is one to which too little attention has been paid during the course of the years in the international programs. Further to complicate the problem, the Institute itself did not have basic data with which to measure truly the effect of its individual projects and their impact upon communities. The program from the beginning was an action program which under the exigencies and pressures of war did not allow for the basic studies and the establishment of measuring rods which were known to be desirable. Under war conditions, the indispensable was dispensed with.

The impact upon crude health problems which could be easily seen by the untrained eye could not be measured to the full satisfaction of the technically trained. Many thousands throughout the hemisphere feel, live, and know the deep and truly great values of this program. Recognizing that a cold routine analysis could not be made, it remained, therefore, to determine how an estimate of the accomplishments of the program could be arrived at with the greatest objectivity. It was apparent both to the Public Health Service and to the Institute that an evaluation of the accomplishments of the program would have to be limited to a comparatively quick but nonetheless expert "look-see," one which, while not exhaustive, would carry authority in the world of public health.

C. O. ROWE, Acting President.

The Evaluation Survey

The survey was a joint undertaking of the Public Health Service and the Institute of Inter-American Affairs. Representing the Service until his death in April 1952 was Joseph W. Mountin, M.D., chief of the Bureau of State Services. He was succeeded by J. O. Dean, M.D., associate chief of the Bureau of State Services. Representing the Institute was Henry Van Zile Hyde, M. D., then director of the Division of Health and Sanitation, Institute of Inter-American Affairs, now chief of the Division of International Health, Public Health Service.

The Evaluation Team

Wilton L. Halverson, M.D., director, California Department of Public Health (team director).

John J. Bourke, M.D., executive director of the New York State Joint Hospital Survey and Planning Commission.

Earl V. Bradsher, director of Welfare Administration for New York City and formerly a staff member of the Public Administration Service.

Edna F. Brandt, assistant chief nurse, Division of Chronic Disease and Tuberculosis, Public Health Service.

Mayhew Derryberry, Ph.D., chief of the Division of Public Health Education, Public Health Service.

George M. Foster, Ph.D., visiting professor of anthropology, University of California, and formerly director of the Institute of Social Anthropology, Smithsonian Institution.

Richard F. Poston, officer in charge of Western Gulf and Colorado Drainage Basins Office for Stream Pollution Control, Public Health Service.

George K. Strode, M.D., formerly director of the Division of International Health, Rockefeller Foundation.

The evaluation team was assisted by A. Joan Klebba of the Institute of Inter-American Affairs and Howard Wheeler of the Public Health Service, who contributed to the development of historical data and made extended search and analysis of file material.

Genesis and General Structure

ACTUAL LAUNCHING of the cooperative health program of the Institute of Inter-American Affairs may be said to have occurred with the activation of its first bilateral agreement, that consummated with Ecuador in February 1942.

This inauguration of the program was in effect a projection of one of the decisions reached in the Third Meeting of Ministers of Foreign Affairs of the 21 American Republics, held in Rio de Janeiro in January of the same year. In a resolution unanimously approved, the foreign ministers had recommended the use of the bilateral health agreement as an important instrument for furthering the security and prosperity of the nations of the hemisphere.

Early Activities

Convened against the backdrop of World War II, the Rio de Janeiro conference stands out chiefly by reason of its achievements in line with a mounting concern for a solid hemisphere front in the face of the Axis threat. But, less conspicuously, it was expressive also of a movement which stretched much further back: a slow and more or less sporadic advance in international cooperation in the Western Hemisphere, the beginnings of which had first become apparent in bilateral conventions for control of pestilential epidemics in the first half of the 19th century.

In the wake of these conventions, as the century was drawing to a close, had come the Committee on Sanitary Regulations, created by the First International Conference of American States, in Washington, D. C., in 1889-90. The first half of the 20th century had witnessed the emergence of the world's first international health organization, the Pan American Sanitary

Bureau, in 1902; a series of 12 Pan American Sanitary Conferences, beginning in the same year; the signing of the Pan American Sanitary Code of 1924, a provision of which made the Pan American Sanitary Bureau the central coordinating health agency of the 21 subscribing states; and a series of 6 Pan American Conferences of National Directors of Public Health, arranged by the Sanitary Bureau.

The hopes and plans of the farsighted in the field of public health were further translated into concrete measures when the foreign ministers met in Rio de Janeiro at the beginning of 1942. It could have been that the urgencies of defense accelerated an already definite movement. At any rate, the bilateral health agreement was recognized and recommended as a means for closer ties and more effective inter-American cooperation.

In the United States, Nelson A. Rockefeller had long been an outstanding figure in the field of inter-American relations. Even before the Second Meeting of Ministers of Foreign Affairs in Havana, in July 1940, he had sponsored a memorandum to President Franklin D. Roosevelt entitled "Hemisphere Economic Policy." This memorandum was to result in the creation of the Office of the Coordinator of Inter-American Affairs, under which the Institute was later to be established.

Mr. Rockefeller had intimate knowledge of the activities of the international health division of the Rockefeller Foundation. A few years after its establishment in 1913, the Foundation had begun promoting public health, the medical sciences, and the natural sciences in a number of the Latin American republics. Methods employed had included the giving of fellowships, grants-in-aid, and scholarship

grants, and the establishment of special services within the structure of host governments.

The Foundation had placed particular emphasis on the training of nationals in public health and allied fields. Many Latin Americans trained with its aid had risen to influential posts in the health organizations of their countries. They were available to help in forming the nuclei of trained personnel if and when a program of cooperation through bilateral agreements between the United States and its neighbor nations should be launched.

Out of Mr. Rockefeller's experience and firsthand observation, therefore, had come appreciation of the importance of health programs in efforts to attain higher economic levels in the countries of Latin America.

With Pearl Harbor and the subsequent inauguration of the first bilateral program, health in its relation to supply of vital war materials became a matter of immediate and grave concern in measures for defense of the Western Hemisphere. When the Institute became a corporate actuality in March 1942, bilateral health promotion was placed high on the list of major programs.

New Departure

The inauguration in 1942 of the bilateral health programs of the Institute of Inter-American Affairs marked an entirely new departure in United States foreign policy implementation. While evaluation must take into account the emergency conditions under which the programs were launched, it must also consider a purpose extending beyond solution of pressing war-created problems. The record clearly indicates a long-range objective, the attainment of which would mean inter-American cooperation as a permanent contribution to global equilibrium.

The Mechanism

Planning of the bilateral programs had been from the premise that the administrative mechanism of the existing multilateral, national, or private philanthropic organizations could not be adjusted to take care of the new foreign political-technical work seen as necessary for the solution of critical economic, food, and health problems identified as obstacles in

the way of attainment of either the immediate or long-range goals. Although the activities of the inter-American system, both governmental and private, had prepared the way for the new programs, it became apparent that a new governmental device would be necessary. Out of this need the program took form.

The mechanism devised had two major parts:

1. A corporation of the United States Government to be known as the Institute of Inter-American Affairs.

2. A unit in one of the ministries of the host government, generally called the *Servicio*, to plan and carry out the projects which would constitute the program in the host country.

These two parts of the mechanism were put and held together by the first interchange of diplomatic notes on the subject of the cooperative program, and by subsequent instruments known as basic agreements between the representative of the Institute and the minister or other designated officer of the cooperating host government.

In the early planning for the health programs, Mr. Rockefeller had made the decision that the administration of health activities should not be carried out directly by the Coordinator of Inter-American Affairs but by a subsidiary corporation. This decision was based in large part on the experience of the international health division of the Rockefeller Foundation, whose years of work had demonstrated the value of placing foreign programs on as flexible a basis as possible without loss of essential administrative control.

The Bilateral Agreements

The Institute's programs were activated from the beginning by agreements entered into with governments of the neighbor nations. After a decision was reached, in consultation with the Department of State, that the establishment of bilateral work was desirable in a given Latin American country, this fact was communicated to the United States Ambassador to that country. After a preliminary authority was given to establish bilateral work, the final authority was usually established through exchange of diplomatic notes between the United States Ambassador and the government of the country selected. This was generally followed by

so-called basic agreements made between the representative of the Institute and the minister of health or a designated officer of an appropriate ministry in the host government. Agreements were in most instances for specific periods of time. At the beginning, 2 or 3 years were usually specified. During the postwar letdown, agreements for only 1 year were made. After 1950, the term was usually 5 years, with funds committed for only 1-year periods.

The Servicio

Under the agreements, both parties provided contributions "in accordance with availability of raw materials, services, and funds," and usually agreed to the establishment of a *Servicio* in the host government.

Before the end of 1942, Dr. George C. Dunham, the first director of the bilateral health work, had supervised the successful establishment of programs in 11 countries. In order of establishment, they were: Ecuador, Haiti, Paraguay, Costa Rica, Nicaragua, Honduras, El Salvador, Peru, Brazil, Guatemala, and Bolivia. In 1943, programs were established in 7 more: Colombia, Panama, Venezuela, Chile, Mexico, Dominican Republic, and Uruguay.

Because of limitation of funds, the programs in Nicaragua, Costa Rica, and the Dominican Republic were terminated in the middle of 1947. The program in Panama was terminated in September 1945. All these programs, except that of the Dominican Republic, were reopened early in 1951.

Table 1. Number and estimated cost of special¹ and cooperative health and environmental sanitation projects in Latin America through June 30, 1951, by class of project

Class of projects	Number	Estimated cost
All projects-----	1, 665	\$103, 015, 915. 56
Special projects ¹ -----	² 125	3, 382, 965. 00
Cooperative projects-----	1, 540	99, 632, 950. 56

¹ Special projects include all projects that were financed directly by the Institute of Inter-American Affairs. These projects did not constitute a part of the country programs that were financed and executed by the *Servicios* in the host countries.

² An approximation based on numbering system used for special projects.

Table 2. Number and estimated cost of cooperative health and environmental sanitation projects in Latin America through June 30, 1951, by country

Country	Number	Estimated cost of projects
All countries-----	1, 540	\$99, 632, 950. 56
Bolivia-----	105	4, 802, 122. 52
Brazil-----	349	26, 391, 059. 19
Chile-----	44	9, 082, 780. 21
Colombia-----	75	8, 961, 382. 04
Costa Rica-----	43	1, 038, 147. 54
Dominican Republic-----	24	571, 436. 34
Ecuador-----	138	6, 860, 722. 44

Guatemala-----	38	6, 195, 365. 54
Haiti-----	89	2, 414, 260. 86
Honduras-----	69	2, 958, 580. 86
Mexico-----	125	8, 366, 374. 38
Nicaragua-----	68	1, 029, 254. 01
Panama-----	29	684, 608. 97
Paraguay-----	39	2, 987, 762. 12
Peru-----	50	5, 872, 413. 00
Uruguay-----	31	1, 415, 517. 47
Venezuela-----	97	7, 025, 249. 13

The agreements usually provided that the Institute would send to the cooperating country a small "field party" of professional and technical personnel, including usually a physician, engineer, and nurse. It was also usually provided that the chief of this field party would not only represent the Institute, but would also be the director of the *Servicio* in the host government, subordinate to the minister or other designated officer in the cooperating ministry.

Under the agreements, all work undertaken was to be broken down into projects, and before these were started a project agreement was to be signed by both the chief of the field party as representative of the Institute and by the designated officer of the local cooperating ministry. This arrangement was to encourage joint planning as well as joint financing and execution of all work undertaken.

Personnel Ratios

Servicios were staffed primarily by nationals of the countries with which the Institute was cooperating. The purpose was not only the utilization of nationals, but, through inservice training, to give national professional personnel necessary experience in the maintenance and operation of the projects, all of which by agree-

ment were to be turned over in time to the host country.

As early as February 23, 1943, the estimated ratio of United States to host country technicians in the field programs was 1:25. By the middle of 1945 there were employed 223 United States citizens (including 30 physicians, 52 engineers, 11 architects, and 36 nurses) and 12,278 national personnel (including 356 physicians, 135 engineers, 172 registered nurses, 1,495 other technical and clerical personnel, 1,202 practical nurses or sanitary inspectors, and 8,918 workmen)—a ratio of 1:55.

During the war years most of the United States physicians and sanitary engineers were assigned from the Office of the Surgeon General of the Army. As of June 1952, the number of Latin Americans working on the health programs totaled 7,134 and the number of United States personnel in the field parties and the technical pool, 119—a ratio of 1:60. Included were 462 Latin American and 15 United States physicians and dentists; 298 Latin American and 20 United States graduate nurses; 94 Latin American and 26 United States sanitary engineers; 59 Latin American and 11 United States civil and other engineers;

and 40 Latin American and 4 United States health educators.

Program Supervision

The chief of the field party was given very broad authority to carry out the program in terms of projects worked out with the minister of the host country or his designated officer. This was in pursuance of a policy of decentralization and development of local field programs under a system by which all projects for a country would be determined locally by joint agreement.

One of the advantages seen in this policy was that it would operate to allay the expressed fears of "invasion of sovereignty." Some general policy lines were kept in view even in the earliest days, however, by the frequent visits paid to the *Servicios* by Dr. Dunham and other staff members. In 1948 a "technical pool," of always less than 10 persons, was created as an additional arm of the Washington office. The president of the Institute and his immediate staff also made field trips for evaluation of accomplishments. Through analysis of required periodic field reports and of project and completion

Table 3. Number and estimated cost of health and environmental projects carried out by the co-operating host countries in Latin America and the Institute of Inter-American Affairs through June 30, 1951, by category of project

Category of project	Number	Estimated cost of projects	Category of project	Number	Estimated cost of projects

agreements on every unit of work undertaken, additional supervision and evaluation of operations were provided for.

Funds

From the creation of the corporation in March 1942, the United States Government financed its role in the bilateral health work by allocation of funds to the Institute. The estimated costs of projects, the amounts of disbursements by the Institute, and the contributions by host governments, from the beginning of the programs through June 30, 1951, are shown in tables 1-4.

The flow of program funds was determined, in the first instance, by the basic and, secondly, by the individual project agreements signed by

both the representative of the Institute and the minister of health or other designated officer of the host government.

Although the total figures give some indication of the project patterns in all of the countries, there was considerable variation from country to country. Projects in Ecuador, for example, were primarily in hospital construction in the early part of the program, and later were primarily to augment water supply. Panama's first program was almost exclusively malaria control. During the first year, construction of water supplies was emphasized in Mexico, but later a wide program including health center organization and construction was developed. The reasons for these shifts in emphasis also varied from country to country.

Assessment Viewpoints and Procedures

Problem: How to judge the effectiveness of technical programs in health and sanitation undertaken during a decade of social, economic, and political complexities. The following is a résumé of criteria and methods used in calculating the values of the bilateral efforts of the Western Hemisphere to help good neighbors help themselves.

TWO BROAD AREAS of analysis lay within the problem of evaluating the *Servicio* effort. They were:

Analysis of the health activities sponsored by the cooperating Latin American countries and the Institute of Inter-American Affairs, with special reference to their role in raising standards of living.

Analysis of the Servicio as an administrative mechanism and of its principal operational techniques, with special reference to its role in strengthening indigenous health services.

The overall question to be answered in the first area was: How well did the health activities sponsored by the Institute assist host countries to make the best use of existing health improvement resources, and how soundly planned was the addition of new health resources?

The second area called not only for the collection of information on the variations in the patterns of the *Servicio* and the operational techniques used, but also for analysis of these devices both in relation to their adequacy in carrying out the individual projects and as forces in strengthening and increasing health improvement resources in the host countries.

In any broad judgment of the performance of the men and women whose responsibility was the planning and execution of programs, three factors would have to be considered:

1. No blueprint based on experience existed for the systematic development of health

service with foreign financial and technical assistance.

2. The selection of projects was a cooperative undertaking—the Institute and representatives of the host country sharing the responsibility.

3. There had been considerable pressure, because of the exigencies of World War II, to waste no time in getting projects under way and to obtain as obvious results as possible.

Analysis of Health Activities

For the purposes of analysis, health activities could be grouped with little overlapping as: (a) auxiliary to military projects; (b) auxiliary to individual economic projects; (c) basic health projects.

The problem of evaluating any one of the groups varied considerably from the problems of the others. But for no group was it seen to be the task of the evaluators to measure the value of health activities in relation to balanced economic development programs in the host country. In fact, in no one of the countries included in the survey was it claimed that there existed such a balanced program, with proper weighting given to advancing living conditions and increasing economic production. This is not to say that the Institute had recognized no relation of health activities to the economic systems of the host governments. To the contrary, it was part of the record that health activities, together with those in education, housing, nutrition, transportation, and irriga-

tion, had been regarded as most important for bringing about the progress that must be realized to enable economic development to take place. For a number of years a division of the Office of the Coordinator of Inter-American Affairs, which included the Institute, had been charged with the development of health and allied activities and had been designated as its "basic economy department."

Services Auxiliary to Military Projects

Little time was given to the evaluation of the health services developed in relation to military projects. These had been terminated even before the end of World War II. Of most of them, scarcely any physical vestige remained locally to bear witness to their accomplishments.

Services Auxiliary to Economic Projects

Typical of undertakings to further specific economic activities was the medical care and malaria control work in the railroad construction camps in the Rio Doce Valley in Brazil. This work helped to make possible the relocation and repair of the railroad connecting the rich iron ore region to the coast. Another example was the medical care and environmental sanitation work in the camps established in Central America in connection with work on the Pan American Highway.

The problem of the evaluators was not to weigh the cost of the overhead services in relation to increased productivity in the area, for if it should be found, for example, that development of the iron ore industry was delayed until the railroad should be reconstructed, the fault would lie with the original economic planning or other factors. The health project evaluators could concern themselves only with the technical qualities of the projects and the question of whether immediate objectives were achieved. Again, since most of these projects had long since been completed, reliance had to be placed on the written record and eye-witness testimony.

Basic Health Projects

Basic health projects constituted about 90 percent of all the health projects sponsored by

the Institute and the cooperating countries. Adequate evaluation required that they be reviewed (a) in relation to the total social development resources and needs of the area they were established to benefit; and (b) as to their technical competence and adaptation to media in which they were introduced. The steps required in the analysis were:

Survey of resources, those existing in the countries as well as the funds and technical personnel available from the Institute.

Survey of needs and assignment of priorities to most urgent needs.

Evaluation of allocation of resources to needs.

Survey of Resources

In underdeveloped countries social development resources are always fewer than social needs, just as economic development resources are always fewer than economic needs. A corollary consideration in evaluation is that social needs in underdeveloped countries are always much greater than resources. Yet resources, and not merely needs, must be the basis for judging as well as for planning social development programs.

Among the most important items of information needed in the survey of resources were: national income and its trend over the 10-year period; proportion of government budget allocated to health and medical services; revenue for health and medical activities from other than public sources; existing health and other social facilities and services; capacity and rating of training institutions for physicians, nurses, and engineers; existing professional and auxiliary medical and allied manpower; compulsory and voluntary prepayment medical care plans; private medical and hospital services; income maintenance resources; and public assistance resources.

Survey of Needs

Throughout the 10 years of operation considerably more work had been done concerning needs than concerning resources. Not only the disease situations but the behavior of the general population in relation to healthful living practices could be used as broad indicators of the most urgent needs.

Evaluation of the allocation of resources to needs was, of course, the most difficult step. The approach could not be based entirely upon the historical experience of those countries which, through several centuries, had evolved more adequate health services. The Latin American countries had not evolved organic services based on strong, long-evolving medical tradition following or paralleling economic expansion. Important health services in Latin America could not be delayed until adequately financed through successful industrialization, but had to be conceived as a necessary overhead or as a mortgage to accelerate economic expansion. Whereas in the more highly developed countries the growth of health services came about from the almost uninterfered-with operation of the law of supply and demand, many of the Latin American countries for several decades had attempted, within their limited resources, to make these services available to those unable to provide for themselves. Moreover, application of the experience of other countries to the problem in Latin America was limited by the fact that there was no broad pattern within which a blueprint could be developed.

Another positive factor limiting the application of the health services found in more highly developed areas was that Latin American countries desired to take shortcuts and make across-the-board use of the great body of technical knowledge that had become available. But, with necessary modifications, the experience of the more highly developed countries could be used for evaluating allocation of limited resources to meet great needs.

It was further recognized that weighing the allocation of resources to needs required consideration of cultural as well as fiscal and technical factors. Cultural factors must include the ways of life, the value standards, and particularly the beliefs and customs of the people with respect to health and illness. Also, the motivation of those nationals whose responsibility was the formation and execution of the health programs in the country must be understood. Without such data, obtained by the application of techniques developed by the social anthropologist and other workers in the

social sciences, it would be impossible to determine the major aids and obstacles to accomplishing the objectives of the Institute's health program.

Analysis of the *Servicio*

Building up health services in a given country with financial and technical assistance from another country immediately introduces a factor that is not present where the development is totally indigenous. This had to be taken into account in the analysis.

Although the same general pattern of operation through a *Servicio* had been recommended to all 18 host countries, in actual operation there had developed about as many patterns as there were *Servicios*. On one hand this wide variation complicated the problem of assessing the *Servicio*, but on the other it increased the experience available for testing the value of different administrative relationships of the *Servicio* to the host governments. It was necessary, therefore, to analyze the effect of the most differing patterns from the following positions: (a) relationship of the *Servicio* to the host government; (b) relationship of the field party to the *Servicio* and to other parts of the host government; (c) organizational structure of the *Servicio*; and (d) principal operational devices employed by the *Servicio* in the execution of projects.

Relationship to Host Government

Analysis of the relationship of the *Servicio* to the host government included consideration of whether the position of the *Servicio* was actually that of a unit in the host government or that of merely an intermediary agency recognized by the host government as a subsidiary office of the Institute of Inter-American Affairs.

If the *Servicio* was actually a part of the host government and not merely an intermediary agency, the relationship had to be studied still further to determine if the program of the *Servicio* was coordinated with that of the indigenous health or allied service "on paper" only, or if the *Servicio* actually did function to stimulate and strengthen the growth of the indigenous service in which it was located.

This included consideration of the relationship of the *Servicio* to the head of the ministry or division of the ministry in which it was located.

Field Party Relationships

Examination of the relationship of the North American field party included reviewing the administrative relationship not only of the chief of the field party to the representative of the host government, but of all the technical members of the field party to the nationals with whom they were associated.

It was necessary to know if these technical personnel from the United States served as project directors, heads of functional divisions in the *Servicio*, or as consultants. If they served as consultants, did they serve as consultants to nationals acting as directors of projects executed by the *Servicio* or as consultants to other professional personnel in the structure of the indigenous service? Over the 10-year period had there been changes in the administrative relationship of the North American personnel to the nationals with whom they worked?

It was also important in the evaluation to determine whether the organizational plan of the *Servicio* was primarily for the execution of projects, or whether planning and evaluation was also recognized as a necessary function.

This involved examination not only of the organization of both the *Servicio* and the field party, but also of the training and duties of the personnel.

The degree to which the *Servicio* succeeded in strengthening indigenous health services was also influenced by the operational devices employed in executing the individual projects. A possible measure of success in any given field in which continuous effort was exerted would be the rate with which change had been made from execution of projects almost entirely by the *Servicio*, with North American personnel serving as directors of projects, to execution entirely by the appropriate agency of the host government. Steps in between would include, of course, execution of projects by the *Servicio*, with nationals serving as project directors, and execution of projects by units of the indigenous health service other than the *Servicio*, with North American technicians serving as consultants.

Unless the planning and operation of projects are truly the result of teamwork between the North American field party and the host government, the activity may be, on the one hand, an almost direct service by the field party, or, on the other, a grant-in-aid or quasi-grant-in-aid from the United States to the host government.

New Foreign Operations Administration

The Foreign Operations Administration, a new agency in which are centralized foreign assistance and related economic operations formerly dispersed among several agencies, came into being on August 1, 1953, in accordance with provisions of the President's Reorganization Plan No. 7. It is responsible for the administration of the two major related assistance programs previously administered separately by the Mutual Security Agency and the Technical Cooperation Administration, as well as for the performance of other foreign aid and related economic functions formerly carried out by the Director for Mutual Security and the Secretary of State. The names "Mutual Security Agency" and "Office of the Director for Mutual Security" have been abolished.

Use of Anthropological Methods and Data In Planning and Operation

Ways of life and thought patterns of *Servicio* staff and their clientele are examined by cultural anthropologists. "Knowledge of people," they emphasize, "is as important . . . as medical science." They speak of interpersonal relations, preventive versus curative medicine, the nature of folk medicine in Latin America, and of general cultural factors, pointing to the basic place of cultural facts in planning and operating public health programs.

DEVELOPMENT of successful public health programs depends not only on the technical excellence of medical knowledge and practice, but also on the socioeconomic potential of a country and the readiness of its people to accept new ideas and habits. The economic handicaps under which public health programs in Latin America must operate are obvious; they are a function of the relatively low productivity of these countries and can be ultimately overcome only by a rising standard of living.

Other problems with which public health programs must cope may be called, for want of a better term, cultural problems. These stem in part from the great differences between the

ways of life and the thought patterns of the people toward whom *Servicio* programs are directed and the ways and patterns of the planners of such public health programs, and in part from lack of understanding of the factors which make for the most effective human relations in any given situation.

Any meaningful evaluation of the bilateral health programs of the Institute of Inter-American Affairs, therefore, presupposes an understanding of the ways of life, the value standards, and particularly the belief and customs of the Latin American people with respect to health and illness. It means, also, an appreciation of the motivations of both *Servicio* personnel and the peoples toward whom the programs are directed, and their attitudes toward each other. The following summarizes pertinent findings, analyses, and areas of agreement concerning the cultural factors affecting the bilateral health programs.

THE SCIENTIFIC APPROACH

Cultural problems cannot be solved simply by hiring friendly, understanding, well-meaning personnel. The problems must be studied and analyzed with appropriate scientific methods in much the same way a difficult biological problem is subjected to scientific examination.

George M. Foster, Ph.D., formerly director of the Institute of Social Anthropology, Smithsonian Institution, and now visiting professor of anthropology, University of California, was the evaluation team member in direct charge of this section of the report. The following members of the Institute staff carried out the special research summarized here: Charles Erasmus (Colombia and Ecuador), Isabel T. Kelly (Mexico), Kalervo Oberg (Brazil), Ozzie Simmons (Peru and Chile), George M. Foster (El Salvador and Chile). The substantial assistance of Dr. Greta Mostny in Chile is acknowledged.

Recent research in the social sciences has made available both data and techniques which make possible a more efficacious attack on these cultural problems than was possible in 1942 when the Institute of Inter-American Affairs commenced operations.

The present work was carried out by cultural anthropologists. They participated in the survey because they were the social scientists of the United States who had given the most attention to studying Latin American contemporary cultures, to finding out the ways of life in the several countries, and to analyzing the relationship of the individual to his culture. But in any long-range program of cultural analysis other social scientists, particularly sociologists and social psychologists, also should be called upon.

Speaking both from general knowledge and results of *Servicio* studies, the cultural anthropologists summarized their views in these words:

"Knowledge of the people is just as important in many aspects of a public health program as is knowledge of medical science. It is therefore recommended that, in Institute of Inter-American Affairs' program planning, provision be made for systematic research into the form and content of the cultures of each country in which work is carried out. Such research should include anthropological, sociological, psychological, and economic studies. It is further recommended that the information so obtained be utilized in planning and operation of *Servicio* projects, both to determine the economic and social potential of a country which sets absolute limits on the changes which can be brought about, and for the purpose of reducing to the lowest possible level cultural barriers to general acceptance of public health programs."

Dual Role of the Social Scientist

This statement, though general, emphasizes the dual role in which the social scientist was found to be of use: participation in the original planning, and subsequently in the operation of the programs.

The planning role stresses the necessity of finding out the nature of a culture, the way of life of the people, the motivations that make them do the things they do, their goals in life,

the objectives they are willing to strive for, and, conversely, the aspects of life that mean very little to them or that they fail to understand. An understanding of the whole cross section of the way of life of the people of a country is almost essential in order to determine limits of any program. What are the people willing and able to accept? What will they reject? What are the social and economic conditions which must exist before certain innovations can be introduced into a culture? If necessary, how can these conditions be brought about?

In the operation of the program, the social scientist's role is that of the educator. After the most practical public health program for a given country or area is determined the people must be convinced that the program really is good for them, that it is in their interest to adopt the new and abandon the old.

Two basic propositions, implicit in the above recommendation, guided the research of the anthropologists:

1. Cultures are integrated functional wholes. Public health programs should be planned and analyzed in relationship to, and as one aspect of, these wholes.

2. There are definite, though imperfectly understood, rules of human behavior which govern the processes whereby changes are brought about in culture. Specifically, popular resistance to public health programs can be scientifically studied, and methods can be developed whereby these resistances can be greatly reduced.

Anthropologists were the first social scientists to formulate the hypothesis that the way of life of a people is an organic, functional, total complex. If the analogy is not carried too far, a culture may be compared to a biological organism in that each of its parts is related in some way to all other parts. Each part fulfills a definite function in relationship to the other parts and contributes to the normal functioning of the body as a whole. Each part, in turn, draws upon all other parts for its own continued existence.

In terms of a public health program, this hypothesis means simply that health and sanitation are not isolated parts of the life of a whole people. They are related to education, social security, economic productivity, distribu-

tion of income, city planning, and a great many other things. Changes in the level of health in any given place may result from changes in the aspects of culture just mentioned; conversely, changes that can be brought about by a given activity are limited by and dependent on the changes that are occurring simultaneously or that can be brought about in these related aspects.

An Exploratory Project

It is possible, the anthropologist believes, to bring about only limited changes in any aspect of culture without accompanying changes in the other aspects of the culture. It is impossible, he believes, to take a very backward country or area and introduce into it a first-class public health program. A specific Institute health program in one of the Latin American countries illustrates this point.

Planning of the program was carried out with great care and thought. There was recognition that a successful public health program depends to a very considerable extent on raising the general economic level of the people. There was recognition that training in home economics and practical farming were integral factors which would contribute to the success of the program. It was decided, therefore, to work in an area where it would be possible to have the cooperation of another agency which was carrying out work in agriculture and home economics. In the small village selected, experimental gardens were set up; training in home economics was introduced; a health post was established, and arrangements were made to bring in a physician and a nurse several times a week to practice both preventive and curative medicine.

Nevertheless, in spite of such planning—excellent as far as it went—certain cultural characteristics of this village became apparent when an overall analysis was made, which raises doubts as to any great degree of permanent success as far as some of the main projects are concerned.

The keystone of the environmental sanitation phase of the work consisted of a privy campaign. Slabs for pit privies were cast locally and given to each of the 100-odd houses in the village. With this preliminary aid, it was expected that within several months most of the

slabs would be in place in back yards, the cost of installation borne by the householder. But 6 months later less than half the slabs had been put in use. The majority were still lying against the front of the houses where they had been placed, overgrown with weeds, and non-existent as far as the householders were concerned. What were possible reasons for this situation?

A census of this village of 600 people was made and the following facts came to light: The village was highly unstable in terms of social organization. About half the inhabitants had lived there for 5 years or less. They did not consider themselves as really permanent members of the community, but rather as migrants who had stopped there while awaiting the opportunity to move on. They felt no attachment to the community, no stake in its future, and they had no interest in making capital investments in something they might not be around to enjoy. A measure of the social disorganization of the village and of the transitory nature of the population was the fact that five professional prostitutes plied their trade, a remarkably large figure in comparison with the average settled Latin American village.

In addition, the land was marginal and wages were low. The least expensive houses in the village were worth from \$18 to \$35. Instructions for building privies were fairly precise, and the cost was about \$10. This meant that people who knew very little about environmental sanitation, who had nothing in their cultural background to make them understand or realize the importance of pit privies, were being asked to make an investment of from 25 to 50 percent of the total value of their homes. It was quite obvious that most of these lower income families could in no way be persuaded to make an investment of this magnitude.

From the census it was also discovered that a considerable number of people in this community lived rent-free in the homes they occupied. The owners were away for extended lengths of time, or they had migrated to other places but had kept their old homes. In order to have their property cared for, they had permitted relatives or friends to occupy the dwellings. Since the actual inhabitants were not the owners and might be put out on a moment's

notice, they were unwilling to spend a relatively enormous sum to build a privy. The owners had little incentive to make such a capital investment since they would not be there to take advantage of it.

Problems of Education

Once it is decided what type of public health project will work in a given place, what is compatible with sociological and economic possibilities, what will have maximum effectiveness in raising general health standards, the problem remains of convincing the people of the need for the project. The planners' ideas as to what is necessary for good health frequently and perhaps usually do not correspond with the felt needs of the people. An important and difficult job of education must be carried out.

The essential problem is this: How is it possible to convince the people that modern medicine and hygienic living are a form of personal health insurance that will keep the individual in better health, make him live longer, and make him able to work more efficiently and enjoy life more fully? How can people who consider much of illness to be due to magical causes or divine will be made to understand scientific concepts of disease and germs, and be made to act accordingly? How can such people be persuaded to take elementary health precautions to avoid disease, to come to the doctor at the first sign of illness, to follow closely the doctor's prescribed treatment, and to avoid the *curandero* (the native medical practitioner) and associated folk remedies?

Fundamentally, the problem is one of persuading people to drop old habits and ideas and to substitute for them new ones which heretofore have been outside their conceptual world. The public health specialist is not operating in a vacuum; his subjects do not feel he is bringing light on a problem about which they know nothing. Rather, he is working in an area in which the subjects already have definite and hard-to-shake beliefs which they are as convinced are correct as he is certain are mistaken. They are not at all sure the doctor's ideas are better than those of the *curandero*; rather, they are often convinced the doctor's ideas are inferior.

Anthropological Techniques

Before attempting to answer some of these questions, the working techniques used by the anthropologists in gathering their data may be noted.

The health center was the focal point of a majority of the analyses. Anthropologists interviewed the directors of these centers, the physicians, nurses, sanitary engineers, sanitarians, and nurse's aides. They sat in the physician's room for as long as 3 hours, observing his techniques with a variety of patients.

Nurses were similarly observed. They were accompanied on visits to the homes; they were studied at BCG-vaccination centers, at "mothers' clubs" where pregnant women were given instruction, and at volunteer workers' training sessions.

Operations of *Servicio* hospitals were also observed. On a random sampling, door-to-door basis, interviewing of populations within the area of health centers was done to obtain a cross section of public opinion with respect to *Servicio* projects.

Health education programs were studied, and limited experimental work in health education was carried out. Tests were given in nursing schools to determine the extent of retention of erroneous folk beliefs among nursing students.

Use was made of the usually rather poor statistical data available.

Informants were "worked" in typical ethnographical fashion to formulate the basic patterns of folk belief concerning health and disease.

The data gathered provided a rather full description of folk medicine in the seven countries studied, including information on the types of illness for which patients will consult doctors and the types which they prefer to take to the *curandero* or treat with home remedies; a good knowledge of health center operations as they impinge upon patients; information on attitudes of patients, potential and former, toward health centers, hospitals, and the medical profession in general; and information on attitudes of physicians, nurses, sanitarians, and other personnel toward their jobs, toward each other, and toward patients, and their ideas of

their problems. Statistical data showing the extent to which *Servicio* programs were patronized were analyzed, as were data on community organization and the possibilities of stimulating better organization as an aid to public health programs. Very significant information on the relationship between curative and preventive medicine, as they bear on public health problems, was obtained.

From the masses of field notes, several general categories of data emerged. Those selected as bearing directly upon the objectives of the survey were (a) interpersonal relations; (b) relative emphasis on curative and preventive medicine; (c) the nature of folk medicine; and (d) general cultural factors which impinge upon public health programs.

INTERPERSONAL RELATIONS

In all countries observed it was apparent that genuinely sympathetic relations between the physicians, nurses, and other *Servicio* personnel, and the patients, are essential for smoothly functioning programs. If the interpersonal relations are good, an average or mediocre program, so far as planning is concerned, can be highly successful; conversely, the most brilliantly conceived program amounts to very little if interpersonal relations are poor, if the program is administered in a mechanical manner, if the people who carry it out are not genuinely sympathetic toward the needs and problems of the people they are supposed to be helping. This observation sounds more like a truism than the result of scientific analysis; it is made because, obvious as it may be, many *Servicio* programs are falling short of their potential because of poor interpersonal relations between staff members and patients.

How can good interpersonal relations be achieved? This is a complex problem which admits of no easy solution. In part, it is due to the rather rigid concepts of class and caste which prevail in Latin American countries, with culturally determined modes of contact between different classes. In part, it is due to a lack of education of the masses, and to innate fear and suspicion of members of one group toward mem-

bers of others. The solution will begin to come as these social barriers are broken down.

Public Health Nurses

There is one key to the problem, however, which holds out great hope for the immediate future. Without exception, the anthropologists were impressed with the importance of the role of the trained public health nurse, the university graduate. In Mexico, in El Salvador, in Ecuador, in Chile, in every country from which information was available, a most important factor making for the success of a public health program was seen to be the availability of graduate public health nurses. Even when the attitude of the physicians is cold and unfriendly, good public health nurses can do much to establish good relations between the health center and the patients.

In a *Servicio* center in a large capital city, for example, some physicians observed were very unfeeling. Nevertheless, a competent group of public health nurses had succeeded in establishing themselves as friends of the people. When the nurses made home visits, children often saw them at a distance and ran with the news to their mothers, who greeted the nurses at the door with a smile and warm reception. Mothers regarded the nurses as real friends, not just as nurses, and as their buffers against the cold formality of the center itself.

Naturally, there are great differences between nurses who have had identical training. Nevertheless, the great majority of Latin American public health nurses who are graduates of good schools are excellent in their interpersonal relations with patients.

The Need for Nursing Schools

Although *visitadoras* (nurse's aides), often with as little as 4 years of basic education, were not observed to the same extent as were the nurses, it was felt that they functioned far less successfully. Often they knew little more than the people they were trying to help; they were timid, unsure of themselves, lacking in basic education, and unable to inspire much confidence. Faith in their ability on the part of professional personnel generally was low,

nurses saying that they must be closely watched all the time, and physicians saying that their turnover was high because of low salaries and because after learning a little they would go into business as *inyeccionistas* (dispensers of hypodermic injections).

The anthropologists felt that every reasonable effort should be made to stimulate the development of more nursing schools, that perhaps even more emphasis should be placed on this aspect of Institute activities than in the past. A question has been raised as to whether *visitadoras* should be eliminated entirely, but practical necessity dictates their continued use. If greater attention is given to the educational and cultural background of future *visitadoras*, and if their training is planned accordingly, it is probable that their effectiveness can be considerably increased. In Brazil, for example, good use appears to be made of them. But *visitadoras* can never be more than a poor substitute for well-trained nurses.

PREVENTIVE vs. CURATIVE MEDICINE

The problem of good interpersonal relations between *Servicio* staff members and patients is linked with the question of curative versus preventive medicine. When the initial studies were made in Mexico, Colombia, Peru, and Brazil, significant differences in the quality of the interpersonal relations were noted. To illustrate, it appeared that there was a closer understanding between staff members and patients in Brazil than in Peru. The first hypothesis advanced to explain this situation was rooted in the problem of class structure. In the Latin American countries which have a comparatively large Indian population, it was observed that educated city people tended to look upon the less fortunate, and particularly the Indian groups, as beings from another world incapable of being assimilated as useful members of national life. At first glance it seemed as if in those countries where these conditions prevailed the quality of interpersonal relations was generally poor.

Following subsequent work in El Salvador, Ecuador, and Chile, it became apparent that this tentative formulation did not hold. In

Ecuador the social gulfs are about as marked as in any American country; yet the physicians and nurses appeared generally to get along well with the patients. Tensions and frictions seemed much less prevalent than in Colombia, where the socioeconomic level was much higher and class differences were less pronounced. The tentative hypothesis of anthropologists—and it should be tested further—is that in those countries where there is frank recognition that for a long time to come curative medicine must be an integral part of any public health program, relations between staff members and the public are good. Conversely, where curative functions are grudgingly accepted by the *Servicio* authorities or avoided entirely, interpersonal relations are poor, and public health programs are much less successful.

Whatever the merits of a public health program based on preventive medicine, the fact remains that the average Latin American is interested in physicians and nurses because they can cure his ills. He usually avails himself of *Servicio* services not primarily to keep well, but to get well.

A survey of 100 families was made in the area of the Beatriz Velasco Aleman Center in Mexico City to find out who patronized the center, and why. Half of the people interviewed had never been to the center. Of the approximately 50 families that had gone, 25 went because they had a sick child that needed attention; 12 went because they could get free milk; and a number of others went because they needed chest X-rays or other clinical services. Only 3 or 4 gave as their main reason for attending the clinic their desire for a routine checkup of an infant. Conversely, one of the principal reasons why mothers had not taken their children was the fact that they were well—"why should one take well children to see a doctor?"

Popular Concepts of Health

This reluctance to seek or accept medical advice when apparently well is deep-rooted in Latin American concepts of well-being. Health, it is thought, consists in feeling well; it is not possible to be ill if one feels well and has no evident symptoms of disease. Since

sickness is due to sins of omission or commission, or to fate or luck, there is very little a well person can or ought to do to keep himself well, at least as far as a physician's attentions are concerned. Treatment is sought only when a person becomes ill.

This feeling about health, which is all too common with the uninformed, is akin to the concept of machinery maintenance: If a machine runs well, obviously it is in good condition and needs no attention; it is logical to repair it only when it breaks down. Periodic checkups have no logical reason or explanation in the minds of people with this point of view. They feel they are doing the center a great favor in keeping appointments, rather than that they are being helped. There seems to be no stimulus sufficiently strong to keep well people coming to health centers, unless certain concessions toward what the people believe they need are made.

Persuasion by Demonstration

Moreover, there is a deep-seated distrust of the motives and knowledge of physicians in much of Latin America. Many people feel that the native *curandero* knows more than a physician, and everyone can and loves to tell of situations in which the physician failed and the *curandero* effected a cure. At the same time, the average Latin American is pragmatic by nature. One of the reasons, therefore, why *Servicio* programs should stress curative medicine is that it is about the only way the physician can show the patient that he knows what he is doing.

To illustrate, in Temuco, Chile, a bad whooping cough epidemic occurred in 1951. Fortunately, health authorities were in a position to vaccinate a large number of children and to arrest the spread of the epidemic. There is no doubt in the minds of most mothers in that town that the physician is a good man to know when whooping cough threatens. And this faith has spread to other inoculations as well; BCG vaccinations are being carried out with a high degree of cooperation from all.

A similar case was noted in Quito, Ecuador. As in much of Latin America, the people in this city believe that fresh air is dangerous, particu-

larly for new mothers. Many complaints against the new *Servicio* maternity hospital were believed to stem from the fact that there is too much fresh air. But even more people remarked, "Fresh air is dangerous, but there is plenty of it at the *Maternidad* and it seems to harm no one, so maybe after all it isn't dangerous." Similarly, new mothers are sent home after a stay of about 5 days, whereas the culture pattern dictates that the mother should remain in bed as long as 2 weeks. There were criticisms of this short stay, but again the remark was heard that the *Maternidad* mothers had more and better babies, with no apparent harm to mother or child, so perhaps the physicians knew what they were doing. Thus, educational work, essential to any public health program, was being carried on in a forceful manner.

The satisfaction of the patient in receiving a public health service which he or she wants and the satisfaction of the physician and nurse in offering a service a patient desires seem to have promoted an atmosphere in which suspicion and tension have been reduced to a minimum, and in which, as a consequence, really good preventive measures can be effected. In the Cerro Barón Center, Valparaiso, Chile, where curative medicine is recognized as just as important as preventive medicine and where no sick child is ever turned away, more than half of the visits are "well baby" visits. By meeting the felt needs of the people—helping them when they are ill—the physicians and nurses have been able to persuade a sizeable portion of the people that it is a good idea to take preventive measures even though an individual is perfectly healthy.

If the premise is accepted that in the long run better world health will result from preventive medicine, the fact must also be recognized that a sizable amount of curative services must be available to develop the conditions essential for a preventive program.

NATURE OF FOLK MEDICINE

If *Servicio* personnel were better acquainted with prevailing concepts and practices of folk medicine, many opportunities would occur for contributing to the overall effectiveness of pro-

grams. Although in Latin America there is no single integrated theory of disease, there are certain common themes and patterns which are so general as to form a framework within which local variations can be studied. These ideas of health and illness are the end result of a long period of fusion of two currents of thought: the American Indian concept of the universe and man's place in it, and the ancient medical heritage brought to the New World by the Spaniards.

Heritage of Hippocrates

Probably the largest single element in the Latin American beliefs is that which has come down through two milleniums from the humoral doctrine of Hippocrates and Galen. Health resulted, according to that theory, when the four humors—blood, phlegm, yellow bile, and black bile—were in proper proportions in the body. These four humors, which corresponded to what were believed to be the four elements of the universe—fire, air, earth, and water—were characterized by opposing qualities of heat, cold, dryness, and moistness. This doctrine, with subsequent modifications and elaborations, reached Spain and Western Europe via the Arab world and was transmitted to Hispanic America, where it remained the basis of medical classification and teaching until the 18th century. Selected aspects of this theory—particularly the concept of heat and cold as qualities of the body, of types of illnesses, and of foods and herbs—became part of the folk belief of most peoples. General concepts of “humors” have also prevailed.

Hence, there has come to be a widespread tendency to explain much illness in terms of “heat” or “cold,” qualities which do not necessarily indicate actual temperatures, but which are innate attributes of substances. Pneumonia, for example, is often classified as a “cold” disease, whereas typhoid fever may be a “hot” disease. Foods, as well as herbs and other remedies, are also frequently classified as “hot” or “cold.” In Xochimilco, Mexico, for example, some of the “hot” foods are sugar, honey, green chile pepper, brandy, black coffee, human milk, garlic, peanuts, onions, and salt. “Cold” foods are rice, spaghetti, potatoes, most

meats, beans, most leafy vegetables, most fruits, coffee with milk, and chocolate. A concomitant belief is that “hot” illnesses should be treated with “cold” medicaments and foods, and vice versa. Although there is no universal agreement as to which foods or diseases are “hot” and which are “cold,” this concept of illness exists in most parts of Latin America.

The “hot” and “cold” distinction provides a scheme for defining under what conditions certain foods can be eaten, what the results will be if the scheme is violated, which remedies can be used for which illnesses, and what the results will be if these rules are transgressed. In short, it appears that “hot” and “cold” distinction provides a general framework of do's and don'ts for much of popular medicine in Latin America.

The “Clean Stomach” Belief

A second common belief is that periodic cleansing of the stomach and intestinal tract by means of strong physics is essential to health. The common Latin American practice of taking a physic every 3 or 4 months is rooted in this concept. The belief seems to be associated with the idea that the liver is a chief source of illness, and that purification of the blood is essential to recovery from illness or maintenance of health. The relatively high proportion of digestive upsets among persons questioned suggests the reason for preoccupation with the stomach, and also explains the extraordinary number of herbal remedies which “wash the stomach clean.” Preoccupation with the blood is exhibited in the general belief that extraction of blood for venereal disease or other tests weakens the patient, and explains why in some communities health authorities making periodic checkups of children have been run out of town by irate parents.

Causative Beliefs

In each country or area studied, folk medicine was found to have a core of principal illnesses, none of which has an exact equivalent in modern medicine. Each illness has a recognized cause or causes, symptoms, and cure, and can be described in the same way the medical practitioner describes the etiologies, syndromes,

and cures of the diseases recognized by modern science.

Some "folk" causes may be said to be "rational," in that they are explained on the basis of the body of empirical knowledge to which the group has access. The knowledge may be erroneous in terms of modern science, but it makes sense in terms of the logical premises of the group. For example, the widespread belief that experiencing abnormal cold is the cause of respiratory illness is "rational."

Closely related to extreme cold as a causative agent is *aire* or *mal aire* ("air," "bad air"), when this is explained as an actual current of air which cools the body, producing various types of illnesses. Contracting *aire* is almost inevitable if one emerges from a house when warm, or if one breathes air much colder than what one has just been breathing. From these beliefs stems the Latin American idea that central heating is unhygienic if not actually dangerous. The violations of "hot" and "cold" food prohibitions, when such violations lead to illness, may also be classified among the "rational" causes.

The role attributed to "microbes," however poorly the term is understood, is another evidence of a rational pattern. For example, the recognizably contagious qualities of such diseases as measles and smallpox make them fall in this category. The belief that gonorrhea comes from intercourse with a menstruating woman or from sitting on a hot rock, that malaria comes from eating certain fruits or not sleeping enough at night, and that "bad odors" cause illness, as well as the Chilean concept of *empacho*, likewise are "rational." The latter is one of the most common folk ailments afflicting children and is believed to be caused by an object such as green fruit, soft bread, or half-cooked food becoming stuck in the stomach or intestines.

"Natural" Causes

In general, illness and injury which are explained as due to such "rational" or empirically determined causes are considered by the folk to be "natural." The most common "natural" diseases have names which correspond to those of modern medicine, and in terms of popular syndromes and sometimes etiologies, but rarely cures, they are essentially the same. They in-

clude whooping cough, colds, grippe, appendicitis, diphtheria, measles, chickenpox, smallpox, intestinal worms, diarrhea, venereal disease, typhoid fever, pneumonia, and tuberculosis.

"Magical" Causes

Other causes may be said to be magical or supernatural in form, in that they lie outside the body of empirical knowledge of the group and are not verifiable or understandable in terms of that knowledge. *Mal de ojo* or *el ojo* ("evil eye") is the most widespread "illness" in Latin America which is explained in magical terms. Certain individuals are believed to have the power, often unintentional and sometimes unknown to themselves, of causing illness in small children by looking at, touching, or admiring them.

Sometimes *susto* ("fright") is magical in origin, in that a malignant spirit or ghost may take possession of an individual or be the cause of the fright. Bewitchment, which involves sticking pins into, or otherwise injuring, rag dolls or images representing a victim, is not uncommon. The belief that a corpse emanates a cold essence which can cause bystanders to fall ill, unless ceremonial bathing or cleansing follow, is another example of a supernaturally produced condition. In El Salvador this emanation is *hijillo*, and in Colombia *hielo de muerto*. *Mal aire*, when the malevolent air is due to evil spirits, is a supernatural happening, as are *entuentos* (postpartum pains caused by contraction of the uterus), widely believed to result when the placenta is not disposed of in ritual fashion.

Psychological Causes

Folk recognition that strong emotional experiences can cause an individual to fall ill is evidenced by the wide variety of sicknesses that are essentially psychosomatic. Those emotional experiences which most often produce physiological results include fright, anger, desire, imagined rejection, embarrassment or shame, disillusion, and sadness. *Susto* or *espanto* results from fright, and, frequently, it is explained as a shock which separates the spirit from the body. The cure depends on inducing the spirit to return to its temporal home.

grams. Although in Latin America there is no single integrated theory of disease, there are certain common themes and patterns which are so general as to form a framework within which local variations can be studied. These ideas of health and illness are the end result of a long period of fusion of two currents of thought: the American Indian concept of the universe and man's place in it, and the ancient medical heritage brought to the New World by the Spaniards.

Heritage of Hippocrates

Bewitchment, which involves sticking pins into, or otherwise injuring, rag dolls or images representing a victim, is not uncommon. The belief that a corpse emanates a cold essence which can cause bystanders to fall ill, unless ceremonial bathing or cleansing follow, is another example of a supernaturally produced condition. In El Salvador this emanation is *hijillo*, and in Colombia *hielo de muerto*. *Mal aire*, when the malevolent air is due to evil spirits, is a supernatural happening, as are *entueritos* (postpartum pains caused by contraction of the uterus), widely believed to result when the placenta is not disposed of in ritual fashion.

Psychological Causes

Folk recognition that strong emotional experiences can cause an individual to fall ill is evidenced by the wide variety of sicknesses that are essentially psychosomatic. Those emotional experiences which most often produce physiological results include fright, anger, desire, imagined rejection, embarrassment or shame, disillusion, and sadness. *Susto* or *espanto* results from fright, and, frequently, it is explained as a shock which separates the spirit from the body. The cure depends on inducing the spirit to return to its temporal home.

Colerina is the term often used for disturbances produced by great anger or rage; in Mexico epilepsy is thought to be due to this experience.

Desires are called *antojos*; unfulfilled food desires of pregnant women may result in birthmarks, whereas those of small children will cause the child to suffer gastric upsets. In Chile, the wise parent, consequently, never denies a child any food, drink, or sweet it wants, however inappropriate it may be. In most countries sibling rivalry is recognized, often in a form in which a child shows unconscious resentment toward an unborn child of its mother. In Mexico this jealousy is known as *sipe*, in El Salvador the child experiencing this feeling *está peche*; in Ecuador *pasión* results; in Peru the term is *caisa*, and in Chile it is *pensión* (anxiety). In Peru embarrassment or shame produces *chucague*, and in El Salvador it causes a bothersome sty known as *pispelo*. The Peruvian *tiricia* is the result of a strong disillusion, and the Ecuadorian *mal de corazón* results from the loss of a loved one, loss of money or property, or some similar saddening experience.

"Popular" Curative Techniques

Folk cures make use of a variety of techniques, the most common of which is the drinking of herb teas. Massage is often resorted to, and it is usually explained as an action that removes the illness or poison from the body. The famous egg-rubbing of the body of a child believed to suffer from the evil eye falls in this category. A warm, freshly laid egg is passed over the body of the patient, then broken open and examined; if a spot appears on the yolk it is assumed that *el ojo* has struck the child. This diagnostic practice is also believed to have therapeutic value.

Poultices are often used, sometimes for mechanical effects but more commonly for magical reasons: in Peru and Colombia a live pigeon is split open and applied to the body for certain illnesses. Diet, with special attention to the "hot" or "cold" qualities of the foods, is of importance in all places. Certain days and certain hours of the day are often used for curing. Religious orations and creeds frequently are recited.

Medical Practitioners

Folk medical practitioners are most commonly called *curanderos* (feminine, *curanderas*), though other terms are encountered. Midwives are called variously *parteras*, *comadronas*, or *curiosas*. Usually these men and women occupy their positions after long periods of formal or informal training, not infrequently as apprentices or assistants to older practitioners. Only rarely do they have divine or supernatural powers to aid in their cures. Sometimes they may use "black magic," but this also is relatively rare. In general, they are honest, sincere practitioners and respected members of the community. Beyond doubt, they frequently cure sickness and alleviate suffering; their knowledge of herbs, as well as of psychology, must be very considerable. In most cases they cannot be looked upon as witch doctors or as frauds or shams.

A Prevalent Dichotomy

A more or less pronounced dichotomy exists in the minds of many Latin Americans between "folk" illnesses and those recognized by medical science. People know that certain types of disease, which do not respond to treatment by *curanderos*, can be cured or prevented by the physician. At the same time they feel that there are other illnesses that are best treated by home remedies or *curanderos*—illnesses which are not understood by physicians, and the very presence of which is denied by physicians. These illnesses are generally those here referred to as "folk" diseases, particularly those described as having magical or psychological etiologies. If an illness is diagnosed, for example, as evil eye, obviously it is poor judgment to take the patient for treatment to a person who denies the existence of the disease. To illustrate, in Valparaíso, Chile, a public health nurse visited a home and found a child suffering from bronchial pneumonia. She asked why the child had not been brought to the health center for treatment and was told, "The child is suffering from evil eye, and you know as well as I that the doctor does not know anything about the evil eye."

This dichotomy is not hard and fast; there

is no sharp line in the minds of all persons between the two categories. Yet the common tendency on the part of physicians and nurses to ignore or ridicule folk concepts of illness undoubtedly at times reduces their effectiveness in that this attitude reinforces the dichotomy. As a result, many genuinely sick persons do not receive proper medical treatment. Although there is a growing awareness of microbes in Latin America, there is a marked tendency to understand by "microbes" those things that cause the illnesses that physicians can cure. Microbes have nothing to do with the *el ojo*, *susto*, and the like.

Several attempts were made to measure the extent of the practical effect of this dichotomy between "folk" and "doctor's" diseases. In Quito, Ecuador, a list of the most common complaints was given to 48 school children of both sexes, ages 11 and 12 years, and they were asked to indicate which illnesses they would take to a doctor and which they would treat with home remedies or take to a *curandero*. It was assumed that the opinions expressed would correspond closely with those which they had heard from parents and other adults. Results are shown in the accompanying table.

In Chile a similar test was made, and similar results were found; the evil eye, *aire*, *empacho*, and *pasmo* (facial paralysis thought to result from exposure to air) were universally agreed upon as being unknown to doctors. Individuals suffering from these diseases would therefore receive home treatment, often gravely prejudicing their chances of recovery since the symptoms are often symptoms of serious illnesses. Anemia, appendicitis, hernia, meningitis, pneumonia, smallpox, typhoid, and the like, generally (but not invariably) were thought best treated by doctors. Results of a survey in Colombia also were similar. Illnesses with magical or psychological etiologies tended to receive home treatment or that of the *curandero*, whereas those due to "natural" causes were more likely to be taken to doctors.

The Physician and the Curandero

The conflict between folk medicine and scientific medicine is summed up in the persons of the physician and *curandero*. Each repre-

Percentage of 48 school children in Quito, Ecuador, who would consult a doctor or a *curandero* for specified illnesses

sents the highest achievement in his field. The attitudes of the people of Latin America toward each, therefore, are pertinent to this study. Unfortunately, the physician frequently comes off second best. This is due in part to the inherent nature of the situation, and in part to native suspicion of individuals in other social classes, particularly those above them.

The *curandero* operates under conditions that are relatively more favorable than those of the physician, from the point of view of impressing the patient with concrete results and apparent success. He treats folk illnesses, the symptoms of which often are so ill-defined that he cannot help but succeed in alleviating them. If the vague physiological symptoms identified with the illness persist or reappear after the cure, the *curandero* can always say that the case has become complicated and requires another series of cures or a different cure, or that a new and different illness has attacked the patient. Also, most *curanderos* do not claim to cure all illnesses, and in many cases can even recom-

mend that a patient consult a physician. These factors establish the *curanderos* in the minds of the folk as fair, open-minded individuals willing to admit their limitations. Finally, the *curandero's* diagnostic techniques do not require elaborate and exhaustive questioning of the patient as to symptoms, case history, and the like. He has certain magical or automatic devices which he applies to specific situations, and the answers follow almost like clockwork. Moreover, there are many cases reported by field observers in which a physician failed to cure an individual and a *curandero* had apparently genuine success.

The physician enjoys few of these advantages. His diagnosis is seldom cut and dried, he cannot guarantee quick results, and he seldom enjoys the faith and confidence accorded the *curandero* because he is from a social class instinctively distrusted by the majority of his patients. Moreover, the physician seldom admits that a *curandero* can cure things which he is incapable of treating, and this is interpreted as meaning that he conceitedly and selfishly believes himself to be the sole repository of medical knowledge—a point of view which the village is loath to accept.

Criticisms of physicians and their professional methods are rife among the patients of the lower class, and such criticisms are usually based on a complete lack of comprehension of medicine, its methods, and its limitations. Several patients pointed out that physicians asked them questions about their symptoms, which showed that the physicians were not as smart as they thought they were. A good *curandero* doesn't have to ask questions, so why should a man who pretends to know a great deal more have to do so? Another patient scornfully pointed out that a president of Colombia died "even though he had 50 physicians at his bedside." The implication was that if 50 physicians could not keep a man from dying, a single doctor in a short interview was almost worse than worthless.

A final handicap of the physician is the general tendency of the people to exhaust home remedies and the arts of the *curandero* before appealing to the physician. The physician, therefore, gets many cases too late to effect a cure and many others which are simply in-

curable. Hence, the failures of folk medicine as well as those of his own profession are heaped upon his shoulders.

Utility of Cultural Knowledge

If the people in Latin America could come to believe that the physicians and nurses understand the folk beliefs concerning health and sickness and approve of some of the folk remedies (for example, isolation, bathing, specialized diet, and herbal teas), but that they simply feel that for many things they have even better methods, it is very likely that the people would evince greater tolerance for modern medicine. There must be great numbers of people who would like to follow a physician's recommendations but are afraid to do so because of folk tradition or because of doubts arising from the feeling that the physicians do not know about some types of sickness.

The utility of knowledge of folk concepts of illness and treatment has been demonstrated. In Chile, as in the other countries, herbal teas form an important part of the *curandero's* pharmacopoeia, and popular confidence in them is great. For infant diarrhea some *Servicio* physicians therefore prescribe, in addition to other remedies, herbal teas. Drinking quantities of liquid is part of the treatment for diarrhea; by the device of teas it is possible to insure boiled, and therefore safe, water. Thus, by interpreting treatment in terms of local belief, the physicians have convinced the mothers that they know what they are talking about, and at the same time, have assured proper treatment of the child.

In Ecuador—and most of the rest of Latin America—it is believed that young children are "delicate," that they are more susceptible to danger from witchcraft, microbes, and other disease-causing agents than adults. A water supply system was installed by the *Servicio* in Tulcan. Adults showed little interest for themselves in a source of pure water—they had been drinking contaminated water all their lives, with no apparent ill effects—but they recognized that their children were more vulnerable than they. By placing the emphasis for the need for pure water upon the health of the children, rather than on health in the abstract, greater interest was aroused.

In Colombia, *malos olores* (bad odors) are popularly believed to cause disease. Typhoid fever particularly is described as a disease associated with bad smells. For this reason, considerable opposition to pit privies exists in some places. Greater attention to means of deodorizing pit privies might very well result in their greater acceptance. Conversely, knowledge of this belief ought to provide a strong focal point to gain support for sanitation campaigns, particularly modern sewage- and garbage-disposal plans.

In Mexico, isolation of patients is a part of the treatment of some illnesses. In most cases isolation stems from the belief that the patient is in a weakened condition and that visitors knowingly or unknowingly might further injure him, particularly through the evil effects of *aire*, of strong body "humors," or of "strong" blood. There is little thought that a patient is coughing germs which may infect others in the family. But, whatever the folk reasoning, an essentially hygienic practice is followed, one that can be successfully utilized by physicians and nurses in the treatment of communicable diseases. The nurse need not remark on the potential danger of *aire*; she can simply say that visitors are undesirable, and the family will probably follow her recommendation, even though she is thinking in terms of contagion and they in terms of magic.

GENERAL CULTURAL FACTORS

More general aspects of Latin American culture patterns bearing upon the Institute's public health programs were also covered in the evaluation. Mexico furnished a striking example. A survey had shown that in a large urban health center 43 percent of registered women discontinued prenatal treatment before delivery, the majority failing to return to the center after the first gynecologic examination. In a nearby semirural health center only 21 percent discontinued treatment. Allowing for some variation because an urban population is less stable than a rural one, there was nevertheless a significant difference between the percentages for the two centers.

The explanation seemed to be based on Mexi-

can (and Latin American) ideas of decorum and modesty. The first prenatal examination comes as a great shock to most women. The examination itself is embarrassing, and is doubly so when it is made by a man. In the rural health center the women were carefully prepared for the experience. The nurse explained just what would be done, why it must be done, that it probably would be done only once during the course of treatment, and that she (the nurse) would be present all the time. In the large center the patients were given little idea of what to expect.

In another center, in Colombia, there was practically no gynecologic examination. The women refused to submit to it, partly because of their own feelings, and partly because their husbands were outraged at the idea of any other man having such intimate contact with their wives.

Even in Chile, where health services were generally well advanced, it was noted in a large health center that the gynecologic examination, such as it was, was done by a midwife, the physician hardly looking at the patient beyond taking her pulse and listening to her chest. On the other hand, in a small center in El Salvador, where women were well prepared by the nurse, there was little embarrassment shown during examinations, and relatively few of the women failed to return for further treatment.

The impersonality of modern medicine runs into a cultural barrier of considerable importance in Latin America: Prevailing concepts of modesty are incompatible with the requirements of medical treatment. At the very least, a thorough and sympathetic explanation appears to be necessary to make gynecologic examinations generally acceptable.

Physician-Patient Communication

Cultural factors pose serious barriers to full development of public health programs in other ways, too. In all countries studied the problem of communication between physicians and patients existed. A significant number of patients, after seeing the physician, did not know what they had been told to do.

In the Cerro Barón Center in Valparaiso, Chile, one of the finest in Latin America, 13

women were asked as they emerged from the physician's room to repeat his instructions. The remarks of 10 indicated that they had failed to profit from the visit. Similar results were found in the other countries. In the Cerro Barón Center, and in some other centers, this problem was partially solved by having the physician write the instructions on the patient's record card. Before leaving the center, the patient would visit the nurse, who would repeat from the card the instructions and explain in greater detail what the patient was supposed to do.

Failure to comprehend the physician's instructions was due to a variety of reasons. Often, a woman patient would be nervous and uneasy in the presence of a man, particularly since she usually was in a lower social class than he; she would therefore be unable to concentrate or to grasp what was being said.

Development of greater rapport between physicians and patients will partially solve this problem. But it must be realized that the manner in which instructions are phrased is also highly important. What appears simple and logical to an educated person may not be at all simple to a less well educated, often illiterate, individual. In the United States, it is taken for granted that patients will understand what is meant by such instructions as "every 3 hours." Yet in much of Latin America this expression is meaningless.

In a Mexican center, for example, the physician told a mother to nurse her baby "every 3 hours." The anthropologist asked the mother at what hours she would feed the child. "At six, seven, eight, and so on," replied the mother. The startled physician repeated his instructions, and the anthropologist again asked the mother when she was supposed to feed the child. The answer was the same. Instructions in terms of time as defined by hours simply were meaningless to this woman.

When significant numbers of a center's patients come from illiterate and low-income groups, groups which are not used to clocks, it would seem wise to work out adaptations of the time concept in terms of phenomena which would have meaning to the people. In most cities, there are factory whistles, municipal sirens, church bells, and the like, which sound at

regular hours. Time points with meaning for each area could be established, and instructions might be phrased in such terms.

A similar case of misunderstanding was noted in Temueo, Chile, where pregnant women were told by the physician to walk 3 kilometers a day if they felt well. At a meeting at which volunteer nurse's aides were being trained, the nurse asked, "How much exercise should a pregnant woman take every day?" All trainees promptly replied, "Walk 3 kilometers daily if you feel well." The anthropologist asked, "How far is 3 kilometers?" This precipitated a lively discussion. Some women thought that the cipher "9," and others that 27 blocks, was a part of the formula. The women were unable to agree as to how far 3 kilometers is in terms of blocks. As in the case of time instructions, these instructions were of no use whatsoever to the audience toward which they were directed because the people were not trained to think in the same terms as the physician.

Hours of Work

Bureaucratic hours and practices were found to constitute a considerable cultural barrier to full acceptance of some *Servicio* projects. In much of Latin America, government hours are from 8 a. m. to 2 p. m., or a similar time period. Allowing time for opening and closing the office the effective hours are considerably reduced. Moreover, since full-time physicians are the exception rather than the rule, many physicians are at the health centers only an hour or two a day and have considerable latitude with respect to arrival time.

To be reasonably sure of attention, then, a patient must come early in the morning and await her turn. For a busy housewife, with many small children to get off to school, morning marketing chores to do and a husband coming home at noon to eat, the loss of half a day was found to be an almost insurmountable difficulty. Loss of time was the single most frequent complaint from health center patients. If some services could be rescheduled for the afternoon (as is actually done in a few centers), it is very likely that more patients would be attracted and that their attitude toward the center would be more favorable. In El Salvador, the semiprivate

Botón Azul, which offers prenatal service from 7 p. m. to 9 p. m., is an obvious success, as its crowded waiting room attests.

The Privy Problem

The humble pit privy may also be used to illustrate the importance of understanding the general cultural configurations of a country. Privy campaigns probably have been carried out in all Latin American countries. Public acceptance in some instances has been good, but all too often privies have been used as chicken coops or as grain silos. Customary posture in defecating is perhaps the single most important fact which bears on the acceptance or rejection of privies.

A coffee planter in El Salvador, for example, built a series of privies, one for each house on his plantation, according to the standard American "riser" model. He was upset when his employees refused to use them. Finally an old man offered the suggestion, "Patrón, don't you realize that here we are squatters?" The planter ripped out the seats, replaced them with a perforated slab floor, and was gratified to find that public acceptance was general.

In La Dorado, Colombia, *Servicio*-built privies appeared to meet all cultural specifications, but were not well accepted. The anthropologist found that an important factor was the belief that bad odors in themselves are carriers of infection and causes of illness. Many people felt they were observing good hygiene in not using privies.

BASIC CULTURAL FACTS

Since greatly increased attention is being given to cultural factors in the planning and operation of public health programs, some of the general theoretical implications of the work done by the anthropologists who participated in the survey may be mentioned. Foremost among these is the question of how much an administrator must know about a given culture in order to carry out a specific project. Ideally, the more he knows about the cultural milieu in which he operates or proposes to operate, the more successful he will be.

It is axiomatic with anthropologists that culture is an integrated, functional whole, in which the separate parts continually impinge upon each other, conditioning and governing, and in turn being conditioned and governed. A change in one part of a culture will produce secondary and tertiary disturbances in other parts, or the primary change may be difficult to induce because of limiting circumstances surrounding adjacent areas of culture.

In Latin America, the success of public health programs is to a very considerable extent dependent on corresponding advances and modifications in a number of other aspects of the culture. These embrace technological devices, systems of social and political organization, and attitudes and values. Bodily hygiene, for example, is more than a question of education and persuasion. It implies the presence of pure water in reasonable quantities—a system of piped water in most instances. But a modern water distribution system requires a maintenance organization, tools and replacement parts, power for pumps, and a sociopolitical structure to administer the system, collect bills, and provide personnel. Improved bodily hygiene, therefore, requires new mechanized devices, new technical knowledge, new attitudes, and new systems of cooperation. The individual who operates on the assumption that a superior idea or technique alone will attract supporters, regardless of the cultural context into which it is introduced, will encounter many frustrating experiences.

Primary Social Data

Although it is desirable to know as much about a culture as possible, there are obviously strict limitations as to what can be known. Social scientists have barely made a beginning in the formidable task of describing the elements of the cultures of the world and interpreting their significance. It must be assumed that for any given program there are certain categories of information about the culture in which the work is to be carried out which are of primary importance, and others that are of lesser importance. A "trial run" in compiling a list of primary classes of data for public health programs gives the following picture.

The points mentioned are suggestive and illustrative and do not pretend to be a definitive catalog.

Folk medicine and native curing practices. The significance of these data has been discussed.

Economics, particularly incomes and costs of living. The cited case of failure to build privies because of their relatively high cost indicates the importance of this aspect of the culture. Inability to pay for medicine is one reason why many persons fail to avail themselves of treatment at the health center. The possibility of achieving a balanced diet is also restricted by inability to pay. Inadequate housing is a great problem in many parts of Latin America. Since in the final analysis the success of public health programs rests upon major changes in the habits of people with respect to diet, housing, clothing, agriculture, and the like, knowledge of the economic potential of an area is paramount.

Social organization of families. In Xochimilco, Mexico, for example, a bride often lives in her husband's home, under the domination of her mother-in-law. A number of cases were noted in which pregnant women failed to follow, or had difficulty in following, health center recommendations because these conflicted with what the mother-in-law thought was best.

Men and women who live together are frequently not legally married. Under such circumstances, a man is less likely to recognize obligations to his companion and their children, and it is therefore more difficult to persuade him to come to the health center for venereal or other treatment. Recognition of these and similar problems makes the responses of patients more intelligible.

Education and literacy. Ability to comprehend the real nature of health and disease, to profit by health education, and to understand and follow the physician's instructions depends on the education and literacy of the people.

Political organization. Local conditions under which physicians and other staff members are appointed, bureaucratic rules which govern operations, and the like, are factors which will affect public health programs. In one country, for example, a large health center, not yet placed in operation, was seriously threatened by the conflicting interests of the state gover-

nor, the local nurses' union, and other bureaucratic factors.

Religion. A basic analysis of religious tenets is not essential, but some parts of the religious philosophy of the people should be known. Are there any beliefs which hinder or directly conflict with proposed programs? Is death, for example, at any age considered a welcome relief from a world of suffering? Are there food taboos based on religious sanction which should be taken into consideration in planning diets?

Basic value system. What are the goals, aspirations, fundamental values, and major cultural premises, consciously or unconsciously accepted, which give validity to the lives of the people in question? What is the practical significance, for example, of a fatalistic approach to life and death? What part does prestige play in determining customary behavior patterns of the people? Is male vanity and ego a factor to consider? What are the ideas of bodily modesty? What are the types of stimuli and appeal to which people respond most readily?

Other types of data. Planners and administrators of public health programs should also have at hand such information as credit facilities and money usages, labor division within the family, time utilization, working and eating schedules, cooking and dietary practices, and the importance of alcoholism.

Categories of culture in which precise knowledge would appear to be of lesser importance include agriculture, fishing, and other primary productive occupations, industrial techniques (except as working conditions may affect health), trade and commerce, religious fiestas and church observances, wedding ceremonies, burial customs, and music and folk tales.

Use of Social Science Data

Specific health programs should be projected against basic data, decisions made as to what specialized additional information is needed, and plans made to gather such information.

For some parts of the world, considerable quantities of these basic or "core" data are available. Latin America is such an area. The

anthropologists who made this analysis were working in a field in which a great deal of preliminary, pertinent work had been done. Anthropologists, and to a lesser extent sociologists, have for more than 20 years been quietly gathering, analyzing, and publishing data on Latin American cultures. Much of this work was done with no thought of immediate practical application. Nevertheless, it represents a large stock of accumulated scientific "capital," much of the value of which lies in the fact that it is generalized and not specialized, and therefore affords a workable background for the institution of a wide variety of programs.

The discovery, classification, and interpretation of new facts merely points the way to continuing research. Simultaneously, however,

this process makes possible the solution of technical problems of steadily increasing complexity and variety, and consequently of expanding utility in the practical or applied context.

Therefore, one of the best uses of the social sciences in the bilateral health programs of the Institute of Inter-American Affairs is the direct assignment to field parties of individuals well versed in the most recent developments in their fields, both to do generalized cultural research and to gather specialized information to facilitate specific projects. Such a plan would make it possible for administrators and program planners to have a continually growing body of precise factual information which, judiciously utilized, would eliminate much of the guesswork which otherwise cannot be avoided.

CIRCULARIZATION

Of PHR Free Mailing List

Early in October *Public Health Reports* will send a mailing list circularization inquiry to all addresses on its official and free mailing lists—not, however, to paid subscribers.

Required by the Joint Congressional Committee on Printing, this circularization necessitates return of a special card confirming correctness of the address and number of copies of *Public Health Reports* sent each month. Health departments, teaching institutions, libraries, and others will want to devote special attention to the circularization inquiry, as the mailing list is composed for the most part of office and position titles, rather than of individual names.

Watch for the special postal card. Complete it fully and return it promptly. Failure to respond by the date specified on the card sent each addressee will result in removal of the name from the mailing list.

Polluted Air, a Growing Community Problem

By HENRY N. DOYLE

Can we achieve that to which every citizen is entitled: an atmosphere of reasonable cleanliness? This review of some of the constructive efforts which communities in the United States are making to study and control the ever-increasing problems of air pollution gives hope that we can learn to manage the great sewer that is the atmosphere.

AIR POLLUTION, the most complex problem facing the environmental hygienist, has been with us ever since man began to use coal as fuel. As technology advances, the problem becomes more acute. In the past, the hygienist hesitated to tackle it because he lacked the necessary equipment to measure the effects on man or to measure the microquantities of contaminants in the atmosphere. Nor was there any general demand for action since the public had customarily associated industrial stack discharge with prosperity.

In recent years, however, the 1948 smog disaster in Donora, Pa., and the growing significance of the Los Angeles air pollution problem have changed the public's attitude from apathy to anxiety. Some measure of this change has been evident in the requests the Public Health Service receives for information on air pollution, a negligible number prior to 1940. Each year sees a significant increase in their volume. In addition, during the past 5 years,

25 cities have requested investigations similar to the one made in Donora by the Public Health Service.

Industry, as well as government, is keenly aware of the growing interest of the public in atmospheric pollution and its health and economic implications. Many millions of dollars are being spent by both for research and correction. Industry itself is spending an estimated \$120 million a year to control air pollution. Even so, few experts believe that in the foreseeable future our cities will have "country fresh" air. Air pollution is a penalty of our modern way of life, and, unless we wish to pay exorbitant prices for certain commodities, we may have to tolerate a certain degree of atmospheric pollution for years to come.

The public in general fails to realize that the atmosphere is the world's greatest sewer. All organic waste, industrial or otherwise, must finally be discharged into the air either directly, through combustion, or by disintegration. Technology, however, in many cases can alter the chemical composition of industrial and domestic organic compounds so as to make them innocuous. In the past, we have used the atmosphere to disperse much of our inorganic waste over large areas. This type of pollution can be prevented with modern dust collection systems and electrical precipitators. Such control measures are costly, however, and they can-

Mr. Doyle, an industrial hygiene engineer, has been chief of the State aid branch, Division of Occupational Health, Bureau of State Services, Public Health Service since July 1952. This article is based on a paper he delivered in College Station, Tex., at the 1953 Short School sponsored by the Texas Water and Sewage Works Association on March 10.

not be expected to be put in general use in the absence of either restrictions or economic advantages.

The effects of atmospheric pollution on people may be arbitrarily divided into four major categories: effects on human health and comfort, toxic effects on animals and vegetation, economic damage, and loss of natural resources.

Health Effects

The effect on health of chemical air pollution has been a controversial subject ever since the use of coal was banned in England during the thirteenth century because of the alleged injurious effects of coal smoke. Current scientific literature is replete with allegations concerning the harmful effects of chemical air pollution. Investigators have attempted to correlate an increasing incidence of respiratory and chronic diseases and an ever-rising rate of lung cancer with the increased severity of pollution. However, in many cases the investigator has been able only to implicate air pollution because of other corresponding and determining factors such as housing, income, nutritional status, and intelligence levels.

A study of the possible relationship of smoke to increased mortality is now under way in England in connection with the recent record fog. Following the 4 days, December 5 to 9, 1952, in which the greater part of metropolitan London was continuously enveloped by a smoke-laden fog, a spectacular rise in deaths occurred.

During this period, abnormally large numbers of persons of all ages died from causes associated with respiratory difficulty. This was similar to what had happened immediately after a comparable fog in 1873, but the death rate in 1952 was much greater and was, in fact, as great as that during the worst week of the last cholera epidemic. Exceptionally high concentrations of smoke and sulfur dioxide were recorded. The highest average concentration was 4.46 mg. of smoke per cubic meter of air and 1.339 parts of sulfur dioxide per million parts of air (1).

Although there are no large metropolitan areas in the United States which suffer extended periods of smoke-laden fogs, significant smogs do occur in certain industrial areas. Largely

because of the enormous difficulties in obtaining reliable data, epidemiological investigations have not been made in these communities. The field of the chronic effects of smog on health thus remains relatively unexplored. Nonetheless, despite the absence of any clear-cut etiology, it is difficult to ignore the vast mass of indirect evidence on chronic effects.

The acute effects of air pollution have been easier to substantiate. Conclusive proof has been afforded by three recorded episodes in which large masses of people were affected. These involved the Meuse Valley, Belgium (2), Donora, Pa. (3), and Poza Rica, Mexico (4). In the Meuse Valley (1930), 60 persons died and several thousands were made ill. In Donora (1948), 20 persons died and some 5,000 were affected in varying degrees. In neither case was the causative agent specifically identified. Most authorities agreed that a combination of contaminants was responsible. A large concentration of industry in a narrow valley and the occurrence of unfavorable weather conditions were circumstances common to both episodes.

The Poza Rica incident (1950), in which 22 persons were killed and 320 were hospitalized, was due to the accidental release of hydrogen sulfide to the atmosphere, which resulted from the failure of mechanical equipment in a sulfur recovery plant. This incident, however, should be classed as an accident since similar possibilities exist wherever large volumes of toxic gases are being processed or transported.

Other isolated incidents affecting numbers of people have also been reported. In one small industrial city, a beryllium manufacturing plant had since 1943 been discharging into the community atmosphere certain beryllium particulates that by 1951 gave rise to 16 cases of chronic beryllium poisoning. Five of the persons so affected have died. Because of the radial distribution of the cases, the source of the poisoning was unmistakably traced to the beryllium plant (5).

To our knowledge, such occurrences are rare. When detected they can be controlled through education, or, in the instance of a recalcitrant industry, by means of local law. Unfortunately, however, health authorities do not always have complete information regarding

the location of plants manufacturing or processing dangerous and toxic chemicals.

In contrast to infrequent acute health effects, sensory discomforts are well recognized by all persons who have had any contact with air pollution in major metropolitan centers. Obnoxious contaminants include those substances which irritate the eyes or nasal passages and those which have a distinct and often irritating odor. The atmosphere in Los Angeles has been particularly affected by lachrymators which cause frequent sensory disturbances. Although these materials have never been proved to be injurious to health, they certainly do not contribute to a sense of well-being.

Toxic Effects

While some of the alleged chronic effects of air pollution on human beings may be difficult to prove conclusively, there is unmistakable evidence that pollutants influence the growth and development of animals and plants. Animals have become sick from eating vegetation which has been contaminated with fluorides from the stack discharges of certain industrial plants. As a result, the teeth of grazing animals in fluorine-polluted districts have been known to deteriorate so much that the animals were unable to feed. Advanced fluorosis in these animals has been associated with such symptoms as lameness resulting from bone lesions, reduced feed consumption, emaciation, diarrhea, decrease in production, and lowered breeding efficiency (6).

The Public Health Service's investigation of the Donora smog incident, which was characterized by a combination of pollutants, revealed that an appreciable number of domestic animals became ill, and some died. Dogs appeared to be the most susceptible, both as to morbidity and mortality.

Air contaminants may also harm plant life. They may discolor crops and reduce yield. Acid gases in the atmosphere may scorch leaves and young plants beyond recovery and may sour the soil. In some industrial areas, there are no crops, gardens, or vegetation because of the harmful effects of air pollutants.

Sulfur dioxide from smelting and other in-

dustrial operations adjacent to forest regions has had a pronounced detrimental effect on tree growth. Continued absorption of atmospheric sulfur dioxide has been known to reduce conifers, which normally maintain their needles for 3 years or longer, to only the current year's growth of needles. Other important atmospheric contaminants which can cause injury to vegetation include hydrogen fluoride, sulfuric acid aerosols, and certain unidentified organic compounds.

Economic Damage

Annual direct losses from air pollution in the United States are estimated as amounting to at least \$1.5 billion, or about \$10 per capita (7). A large part of this loss obviously is caused by damage to or destruction of vegetation. In 1950, for example, approximately \$300,000 worth of leafy vegetable crops alone were damaged by smog in the Los Angeles area (8). Contributing to the total expense is damage to property, including the discoloration and disfiguration of buildings. Corrosive acid gases in the atmosphere eat away stone, mortar, and metals. It has been reported that sheets of galvanized iron had a life span of 3-6 years in Pittsburgh as compared with 7-14 years in a smoke-free community and that copper would last only 10-20 years in Pittsburgh, whereas it would last indefinitely where there is relatively little atmospheric pollution.

The interiors of buildings are also subject to soiling and corrosive action on walls, rugs, draperies, linens, and clothes. Replacements must be made frequently. Soap, laundry, and dry cleaning bills are increased, adding to the household living costs. The Mellon Institute of Industrial Research estimated that in 1913 over \$2 million was spent in Pittsburgh on extra laundry and dry cleaning of clothing soiled by soot; another \$75 million was spent on cleaning and renewal of wallpaper and curtains.

There is a loss of merchandise in stores. Polluted atmospheres also cut down the normal amount of sunlight. More artificial lighting is needed, thus increasing the cost of illumination. Air contaminants may even force people to move to another community, thus causing a drop in real estate values.

Loss of Natural Resources

A further loss by air pollution lies in the large tonnage of valuable materials emitted into the atmosphere. The Mellon Institute estimated that in 1926 about 160,000 tons of nitrogen were lost in smoke from soft coal used in American households. This amount was equal to nearly half the inorganic nitrogen used that year in the United States. Although this nitrogen would not be recoverable, it serves to illustrate the magnitude of losses by industrial processes.

According to the United States Bureau of Mines, 700,000 tons of manganese, representing approximately 50 percent of our yearly requirements of this critical commodity, could be recovered annually from processing losses. Among the rare metals, germanium, gallium, rhenium, and selenium are being lost in flue dusts and smelter discharges; recovery processes are yet to be developed. Great Britain is reported to be dissipating yearly in coal ash 1,000 tons of gallium and 2,000 tons of germanium into the air (9).

The economic value of reclaiming substances previously discharged into the atmosphere may be illustrated by the experience of the Canadian smelter which formerly caused crop damage in the State of Washington. The smelter now uses its sulfur dioxide in the manufacture of fertilizer. As a result, the returns to the smelter from this operation exceed the value of its smelting operations.

Major Studies

Until relatively recently, measurements of the degree of air pollution consisted of fall-out studies in which concentrations were expressed as tons per square mile of surface. Such studies were helpful in demonstrating that, in many highly industrialized areas, the dust-fall amounts to hundreds of tons per square mile per year. This system of measurement, however, failed to identify the contaminant and gave no index of the diurnal variation. Consequently, it had critical shortcomings as an aid to effective abatement and control of air pollution. With recent progress in instrument development, the chemist is now able to evaluate both quantitatively and qualitatively the atmospheric particulate matter and certain of the gases. Concentrated research, though, remains

Table 1. Concentration of metallic elements urban atmospheres in micrograms per cubic meter of air

to be done on the isolation and identification of certain materials, particularly the hydrocarbons and other organic compounds, which exist in the atmosphere in trace amounts.

A number of studies of various air pollutants have been made in major industrial areas. Table 1 shows an analysis of the metallic constituents of the atmosphere in three cities: Detroit, Windsor (Ontario), and Charleston, W. Va. (10). In each instance, the same methods of sampling and spectrographic analysis were used. It is evident that certain elements such as iron, calcium, magnesium, and silicon constitute the bulk of the metallic elements (80 to 90 percent). It will be seen in table 1 that the elements below manganese generally occur in amounts less than 0.1 microgram per cubic meter. In comparison with the predominant metals, those of lower concentrations—manganese and below—are commonly considered to be more toxic. This uniformity of findings, if substantiated by further study, is of great importance in that it indicates a common problem in large and diversified industrial areas.

An interesting comparison of the area distribution of certain elements in Detroit and

Cincinnati is shown in table 2. As might be expected, there is an increase in the total particulate atmospheric load as one moves from the residential section to the center of the industrial area (11). Organic matter constitutes the major portion of air contaminants, since the metallic elements comprise only from 5 to 11 percent of the total weight. According to some authorities, the bulk of the organic matter is considered to be gasoline combustion products, organic chlorides, ketones, aldehydes, and organic acids.

Table 3 illustrates the concentration of some organic constituents found in the Los Angeles area (8). Insufficient work has been done to determine whether or not a common pattern of organic constituents exists in other areas.

In an air pollution study conducted in Salt Lake City in 1951, the contaminants were collected by electrostatic precipitation rather than by filtration, were accumulated for the duration of the study, and were chemically analyzed. Table 4 illustrates the inorganic constituents according to their relative proportions. Here again is evidenced the same general order of the metallic elements as was found in Detroit and Charleston. The only exception is silicon, which, in this case, dropped from 1st to 6th place. Despite the fact that Salt Lake City is a nonferrous smelting center, the order of the metallic elements is almost identical to that for the Detroit area where the industries are primarily ferrous in nature.

The accumulated material from the Salt Lake City study was split into benzene soluble and insoluble fractions. The benzene soluble and combustible fraction constituted 22 percent of the sample and was assumed to consist of tars and hydrocarbons; the benzene insoluble and combustible fraction (48 percent of the sample) was assumed to be soot and insoluble tars. The difference (30 percent of the sample) was ash or inorganic matter. Comparable data on the organic fractions for other areas are not available. Photomicrographs of the particulate matter collected during the Salt Lake City smog of November 28, 1950, are shown in figure 1.

Weather conditions greatly affect the concentration of atmospheric contaminants. In the Cincinnati study (11), it was found that the concentration of the particulate matter was greater in the winter months by a ratio of almost 2 to 1; whereas the number of particles present in the atmosphere increased by a ratio of almost 4 to 1. As is evident in table 3, the degree of contamination by the gaseous material in Los Angeles is much greater on days of reduced visibility than on days of good visibility. The same observation may be made for the particulate matter. For instance, the concentration of all the contaminants, except formaldehyde, shown in table 3 increased by a factor between 5 and 6; the formaldehyde concentration was only doubled. Other studies done in Los Angeles have proved that days of

reduced visibility correspond with certain meteorologic conditions, especially temperature inversions.

Figure 2 illustrates the effect of inversions on the intensity of the Salt Lake City smog. On February 8, 1951 the atmosphere was thermally normal or unstable whereas on February 15, an inversion existed, resulting in atmospheric stability. On both days the wet bulb temperature and wind velocity and direction were of the same order of magnitude. Relative humidity was 55 percent on February 8 and 80 percent on February 15.

From the foregoing, several conclusions may be drawn:

The atmosphere is a great receiver and diluter of civilization's waste products.

It is suspected that there is a relationship between air pollution and certain chronic illnesses in humans although this has never been definitely proved. There is no doubt, however, that under certain combined topographic and meteorologic conditions, acute illness and death in man may occur.

Certain atmospheric pollutants when present in sufficient concentration have definite toxic effects on animals and vegetation.

Atmospheric pollution causes great economic waste and a loss of valuable mineral resources.

There appears to be a remarkable similarity

in the qualitative pattern of the inorganic pollutants in large industrial areas which have climatic and industrial resemblances.

Contaminants are largely organic in nature, but insufficient information is available on the organic constituents to conclude that there is a similarity in the organic contaminants in industrial areas.

The degree of pollution in any area is affected by seasonal and meteorologic variations.

Governmental Activities

There is no legislation governing air pollution on the Federal level although several bills have been introduced into Congress to give Federal agencies, chiefly the Bureau of Mines and the Public Health Service, authority to engage in certain research aspects of the problem. Major Federal activity in the field of air pollution in recent years has been confined to a comprehensive investigation of the Donora disaster by the Public Health Service. Currently, at the request of the International Joint Commission of the United States and Canada, a study transcending international borders is being conducted in the Detroit-Windsor area by the Public Health Service and the Canadian Government (12).

At present, almost every State and local in-

Figure 1. Photomicrographs (magnification 100 \times) show the particulate matter collected by a cascade impactor in the fall of 1950 during a Salt Lake City smog. The impactor separates and collects atmospheric particles according to size. Stage 1 shows the larger particles. Stages 2 and 3 show the intermediate size particles—the larger ones visible are probably due to impaction and coalescence. Stage 4 shows the smaller particles.

dustrial hygiene agency is engaged to some extent in air pollution studies. Industrial hygiene agencies are well qualified for such activities because of their experience and knowledge in dealing with a wide range of airborne contaminants. In many instances, they have had to assume this responsibility at the expense of their regular activities.

Pennsylvania is among the States with a full-scale air pollution program. Since early in 1949, when the Pennsylvania General Assembly authorized funds for the study of the problem, an air pollution unit has been operating within the bureau of industrial hygiene of the Pennsyl-

vania Department of Health. The staff studies technical phases of air pollution problems, conducts investigations wherever necessary, and assists communities in the evaluation of local problems. The air pollution unit is fully equipped with testing apparatus and meteorologic equipment and has a mobile laboratory and apparatus for the determination of atmospheric sulfur dioxide concentrations.

In Maryland, air pollution control constitutes an important activity in the divisions of industrial hygiene of the State Department of Public Health and the Baltimore City Health Department. While specific air pollution legislation

has not been passed, the State legislature has appropriated moneys for this work for the past 3 years. Activities of the State unit have generally been confined to investigating local problems created by specific industries. To facilitate its work, the State has available a mobile laboratory and testing equipment. Requests for assistance with air pollution problems have been particularly numerous in Baltimore. During the 1952-53 fiscal year, 70 percent of the 230 complaints received by the Baltimore industrial hygiene unit dealt with community air pollution.

In New Jersey, too, the bureau of adult and industrial health devotes much of its time to air pollution problems. The bureau not only investigates complaints, but also engages in research on methods of sampling. At the same time, it is attempting to bring about a better understanding of the problem by the general public. The bureau is presently conducting a study of the highly industrialized Perth Amboy area. This study is an excellent example of how a State can plan and initiate an air pollution study and maintain the confidence and support of both the public and industry.

The West Virginia division of industrial hygiene recently completed a study in the Greater Kanawha Valley industrial area, which was requested by an industry and citizens' advisory committee, and industrial groups contributed \$25,000 to help defray a large part of the cost. The Kettering Laboratory and Institute of Industrial Health assisted in the technical study, and the Public Health Service gave consultant services. The study clearly defined a need for continuing studies and for a long-range plan based on technical principles that would enable the best control possible within the limits of sound economy. The report also emphasized a need for uniform, accurate, and continuing records of emissions to the atmosphere by industry.

The Oregon Legislature in 1951 established an Air Pollution Authority as a part of the State health department. The authority is directed to investigate the extent and magnitude of air pollution in the State and to develop a comprehensive program for the prevention and control of all sources of air pollution.

Air pollution activities are more prevalent on

the local level. Many large cities, including Los Angeles, New York, Cleveland, Detroit, and St. Louis, have recognized that smoke control is but one aspect of the air pollution problem and, in addition to previously existing smoke abatement units, have established air pollution control units. Most of these city units are policing agencies, which base their actions on sound technical studies and reasonable standards.

The activities reviewed above are but a few examples of the air pollution work being conducted by various States and municipalities. They are intended only to depict the diversity of activities and illustrate different methods of approach.

Various private agencies have also been active in the field of air pollution. Particularly noteworthy is the fine work being done by the Kettering Laboratory and Institute, the Battelle Memorial Institute, the Industrial Hygiene Foundation, the Lake Carriers' Association, the Manufacturing Chemists' Association, and many universities as well as numerous other organizations. We look to these agencies to develop better equipment for air pollution control and to bring about a better understanding of the problem on the part of industry and the public.

The Job Ahead

Air pollution is not an insolvable problem. However, its solution is going to require patience, persistence, research, and a mutual understanding among the public, government, and industry. Each can and must play a definite part in bringing about cleaner air for our towns, cities, and metropolitan areas.

The public must realize that it is a part of a modern technologic society and that its continued high standards of living call for full industrial production. The average man must further realize that he too is a contributor to air pollution because of his automobile, his backyard incinerator, and often, because his home heating system is inefficient. The impact of chemical air pollution on our health and resources has been manifested for only a relatively short period. Given sufficient time, the problem can and will be solved. It is not meant to imply, however, that in the meantime a citizen should stand idly by and possibly have his

Figure 2. Illustrations of effect of inversion on smog intensity in Salt Lake City, February 8 (top row) and February 15 (lower row). The graphs show aerological soundings—note inversion on February 15. Next are filter paper samples (volume 450 cubic feet) of smog stain—the February 15 sample is almost black. The difference in visibility on the two days is emphasized by the identical views overlooking the Salt Lake Valley.

courage new industry or industrial expansion. Those industries which are already in the community should be expected to abide by reasonable rules and regulations which have been found to be effective in other areas. Persuasive methods should be used to secure self-initiated corrections on the part of industry. At the same time, the community should realize that it too is quite often a violator of good municipal air pollution standards by virtue of burning trash heaps, allowing the operation of inefficient boiler plants in municipal power generating plants, and permitting inadequate regulations controlling the type of fuel and combustion plants for private homes, apartments, and office buildings.

Industry must adopt the good neighbor policy. A community cannot tolerate a dominant industry. For an industry to be successful, it must learn to live in complete accord with the inhabitants of the community. In selecting locations for future industrial sites, industry must not only consider such items as transportation, availability of raw materials and labor, but it must also add new criteria: topography and meteorology. If toxic chemicals are to be discharged into the atmosphere, it must locate where meteorologic conditions are conducive to the favorable dissemination of smoke and other contaminants unless adequate control of pollutants is assured. Industry must also appraise its stack effluents. It must assure that highly toxic compounds such as beryllium are controlled within narrow limits. This may in some cases necessitate studies to determine the toxicity of new compounds and those metals which have recently gained industrial significance.

Because of the magnitude and complexity of the air pollution problem, the solution must obviously lie in concerted action. An individual industry can rarely afford to engage in specialized toxicologic studies of suspected harmful contaminants. It must therefore draw upon the resources of universities, research foundations and other private organizations, and government. Furthermore, it must accept the community as a partner in a jointly recognized and accepted effort to cleanse the atmosphere of excessive and harmful contaminants. With such a spirit of mutual confidence and unity, we shall be able to cope with the problem

before a threatened saturation impels desperate action as in water pollution. Indeed, there is every hope and reason that we can achieve what every citizen is entitled to: an atmosphere reasonably free from chemical pollutants.

Efficient Domestic Stoves

Most of the coal used domestically in 1948 (37 million tons) was burned in open grates and kitchen ranges of traditional design and low efficiency. Although about half the present domestic consumption of coal could be saved by its more efficient use, a very much smaller saving would, no doubt, be effected since the greater efficiency of the newer appliances would be used to provide greater comfort for the same fuel outlay.

Within recent years, many manufacturers have made successful efforts to design more efficient fires and stoves for domestic heating. The Fuel Research Station of the Department of Scientific and Industrial Research has tested many of these appliances, and the Minister of Health in consultation with the Minister of Fuel and Power and other Government departments has issued a list of approved appliances.

The sale of these newer and more efficient appliances has greatly increased since the end of the war. Increasing attention is being paid to improving the insulation of houses so as to conserve heat and so to reduce the amount of fuel used.

Fuel-Saving in Industry

It is in industry, perhaps, that the greatest strides have been made in the more efficient use of fuel, especially in the generation of electricity which now requires about 30 million tons of coal a year. In 1921, 1 kilowatt-hour of electricity required 3.4 pounds of coal; now, only 1.4 pounds is needed.

During the war, in order to eliminate from merchant ships the telltale smoke plumes that occurred soon after firing, the Fuel Research Station designed smoke-eliminator doors for the furnaces. These provided the extra secondary air when it was needed. This principle has now been extended to the design of smoke-eliminator doors for a number of shell-type boilers.

The Ridley Report

The recent report of the Committee on National Policy for the Use of Fuel and Power Resources (the Ridley report of 1952) is most

germane to this issue of fuel efficiency and smoke abatement. It makes the following recommendations:

Development of more efficient types of open fires to burn coal more efficiently and smokelessly.

Increased use of gas for domestic heating during peak loads on electricity generation.

Expansion of the fuel-efficiency advisory service.

Financial incentives to firms installing efficient equipment for combustion.

Prior approval for industrial and commercial heating plants.

More training schemes for stokers.

Replacement of steam railway locomotives by other types.

Wider use of low-temperature carbonization for production of smokeless fuels.

More general adoption of smoke abatement bylaws under the Public Health Act of 1936.

More smokeless zones.

In Detroit

Detroit's present air pollution control program was started in 1947 when a committee of the Engineering Society of Detroit, at the request of the Department of Buildings and Safety Engineering, drafted a comprehensive air pollution control ordinance. Upon enactment of the ordinance, which replaced Detroit's smoke abatement ordinance, the Bureau of Smoke Inspection and Abatement was reorganized on an engineering control basis with a staff of 3 engineer administrators and supervisors; 17 air pollution inspectors; 5 office personnel; and 2 chemists, classified as industrial hygienists.

The air pollution control ordinance is enforced primarily by obtaining compliance. Court action is resorted to only for recalcitrants

By Benjamin Linsky, M.S.E., P.E., chief smoke inspector of the bureau of smoke inspection and abatement, Department of Buildings and Safety Engineering of the City of Detroit.

because, when a case reaches the courts, the bureau believes it has failed to "sell" the requirements of the community to the violator.

Control Alerting

Visible air pollution is controlled in Detroit by 15 district air pollution inspectors as well as by an observer for the bureau who dispatches two radio-equipped automobiles manned by air pollution inspectors. The observer watches for the sources of excessive air pollution, while they are active, from any one of several high buildings in different parts of the city. Citizen complaints are also served by the radio-equipped automobiles.

Measurements of "streetosphere" concentrations of pollutants are obtained to evaluate the need in a specific neighborhood for corrective work at a specific point source and to correlate such concentrations with various kinds of effects. Stack samples are obtained when it is necessary to evaluate air pollution emissions at the source.

Local industries and city departments operating large plants have been persuaded to engage in research and development when no technical controls for specific air pollution emissions were known. Examples of some recent and current projects are:

An intensive examination by the Chrysler Corporation of its problem of controlling dirtying particles from the continuous melt gray iron electric furnaces at its Dodge-Winfield plant.

The research by the city departments of public works and water supply into the problems of collecting dust particles from high-temperature gases at incinerator and sewage disposal plants.

The Aurora gasoline refinery's development of a neutralizer for odorous gases from a spent-caustic regenerator.

The over-fire air system of the Detroit Edison Company for reducing smoke from its large multiple-retort-stoker-fired steam generators.

Results Over 5 Years

About \$14 million has been spent for installations of direct air pollution control in 5 years.

This sum is for corrections required by violation notices from the bureau and does not include the large number of equipment changes made where installation permits were not necessary.

Horizontal visibility, in the absence of rain, fog, snow, or sleet, has increased measurably. Dustfall in industrial areas has been reduced.

More than 140,000 tons of fly ash a year is now being caught in fly ash collectors. Large tonnages of chemical and other dusts are also being caught. Emissions of industrial gases such as hydrogen sulfide and hydrofluorosilicic acid have been reduced.

Smoking chimneys are fewer and less frequent. A white shirt can be worn a full day. Fly ash does not accumulate along curbs and in store doorways.

Cooperative Control Efforts

The Bureau of Smoke Inspection and Abatement engages in limited research work, when no industrial sponsorship can be obtained. It freely exchanges ideas with other air pollution specialists in public agencies and in private industry. Its activities are deliberately and conscientiously integrated with related local agencies. Thus, the planning and zoning agencies are sources of reports of neighborhood problems as well as recipients of technical air pollution data and recommendations from the bureau. The bureau works continuously on improved air pollution instrumentation in cooperation with the division of industrial hygiene of the health department.

Similarly, solutions to air pollution problems which involve fire hazards are worked out cooperatively with the fire department. The local water pollution control agency is consulted about wet methods of air pollution control. Health effect determinations made by the health department guide the bureau's engineering control work.

There is still another relationship between the bureau and the Detroit Department of Health. To avoid duplication of specialized laboratory facilities, special sampling instruments and the two industrial hygienists in the bureau are stationed in the laboratory of the industrial hygiene division of the health depart-

ment. These men work under the direct supervision of the division, performing general industrial hygiene work with emphasis on air pollution sampling and analysis. When the bureau requires such measurements, the industrial hygiene division assigns men to work with the bureau's engineers and air pollution inspectors. The measurement data is then sent to the bureau for evaluation and use. Thus, in exchange the bureau is entitled to 2 man-years of air pollution measurement work per year from the industrial hygiene division.

Detroit-Windsor Study

As a byproduct of Detroit's request for abatement of the nuisance caused by smoke from ships plying the Detroit River, an international waterway, the Detroit-Windsor air pollution study of the International Joint Commission (IJC) of the United States and Canada was started. Recognizing parallel interests in various phases of the study, several local community groups in the Detroit area have contributed services, equipment, personnel, and funds.

The Detroit Edison Company erected pole supports and furnished high-volume filters. The Detroit Department of Health employs and supervises the health effects staff for the Detroit portion of the study. It also sponsored the stack-sampling course at the University of Michigan. The General Motors Corporation furnished all facilities for the joint industry conferences on the air pollution study.

The bureau pays the rent for the quarters of the United States section of the IJC Technical Advisory Board. The bureau serviced most of the high-volume filters daily and scheduled its Thomas autometer so that data could be coordinated with the IJC Technical Advisory Board's autometer. It also prepared detailed pollution source maps.

The area-wide Detroit-Windsor study will determine valid correlations between air pollutant concentrations and the effects on vegetation, corrosion, soiling, visibility, and health detriment. Already under way are a vegetation effects study and a pilot field study of health effects of urban air pollution in both Detroit and Windsor.

In Los Angeles

Comprehensive investigations on the causes and effects of air contaminants in the Los Angeles area show that, for the present, air pollutants can be related to such effects as reduction in visibility, eye and throat irritation, damage to vegetation, and local nuisance.

The Smog Mixture

Aerosols, gases, and vapors are the principal ingredients of smog in Los Angeles County. Dusts, smoke particles, and condensed fumes are obvious pollutants—detrimental because of physical characteristics causing reduction of visibility. The atmospheric oxidation of sulfur dioxide to sulfur trioxide and the formation of sulfuric acid mist contribute to this effect. Where atmospheric conditions provide time for the oxidation of certain hydrocarbons in the air, the polymerization of the oxidation products add to the haze. Droplets of organic acids and peroxides undoubtedly exist under certain moisture and temperature conditions. These, too, result from hydrocarbon reactions in the air.

The vapor or gas phase of smog is predominantly hydrocarbon. Olefinic, branched-chain, and cyclic compounds present in gasoline vapor are readily oxidized in the presence of sunlight and oxides of nitrogen to produce gases which are eye-irritating and damaging to vegetation. Ozone, a byproduct of the photochemical reaction, further aids the oxidation and leaves a residual ozone concentration which may reach nuisance proportions in the mass of polluted air. The Los Angeles studies have shown that the presence in the air of quantities of aldehydes, organic acids, and peroxides is largely accounted for by the reactions which occur.

Samples of the air taken under intense smog conditions in Los Angeles were analyzed by acceptable methods for identifying microquan-

By Gordon P. Larson (Lt. Col. Ret.), director of the Los Angeles Air Pollution Control District since 1949.

tities of materials. The results are shown below:

Aerosols	
Ether-soluble aerosols.	Lead.
Sulfuric acid mist.	Aluminum.
Carbon.	Calcium.
Silicon.	Iron.
Gases and Vapors ¹	
Acetylene.	Methyl chloride.
Aromatics.	Nitric oxide.
Benzene.	Nitrogen dioxide
Isobutane.	Nitrous oxide.
n-butane.	n-pentane.
Butenes.	Phosgene.
Carbon tetrachloride.	Propane.
Ethane.	Propylene.
Ethyl benzene and/or xylene.	Sulfur dioxide.
Formic acid.	Toluene.
Methyl Cellosolve	Trichlor ethylene.
Unsaturated hydrocarbons ranging from C_2H_4 to $C_{12}H_{24}$.	
Products of oxidation of the above unsaturated hydrocarbons (aldehydes, peroxides, ketones, and organic acids).	

¹ In addition to normal gaseous constituents of the atmosphere.

The aerosols are listed in order of importance as they affect visibility, which has been determined by a relative pollution index.

Results of Controls

Control efforts in Los Angeles have been highly gratifying. Over 600 tons of air pollutants once discharged daily into the atmosphere are now being withheld. Industry accomplished this by spending over \$12.5 million for control equipment.

Valuable sulfur is recovered by the 360-ton daily reduction of sulfur dioxide at the refineries. The amount of sulfur dioxide in the atmosphere has been reduced by 50 percent. Refineries have reduced losses of gasoline vapor, recently identified as a pollutant, by 100 tons a day.

Control equipment on metallurgical plants, in rock-crushing, asphalt paving and grinding processes, and in the food, paint, roofing, fertilizer, and soap industries is daily collecting 70 tons of dust, fumes, and other aerosols.

The efforts of the Air Pollution Control District of the County of Los Angeles to improve combustion, especially in industrial and com-

mercial incinerators, and to eliminate smoke at burning dumps have accounted for the removal of 60 tons of smoke, 50 tons of organic acids, and 10 tons of aldehydes from the air. The dieselization program of railroads has further reduced contamination from smoke.

As a result, the number of days of intense smog has decreased; the average visibility has increased; and the concentration of many pollutants has decreased. However, the level of atmospheric pollution is still too high. No end is in sight to the rapid increase in population and the expansion of the industrial community. Estimates indicate a growth to 16,000 industrial plants and 6,000,000 persons in Los Angeles County by 1960.

New Frontiers for Study

Certain phases of the Los Angeles smog problem must still remain in the hands of the scientists and development engineers. Useful information for air pollution zoning programs is very much needed. In Los Angeles, the expansion of the community, and the critical weather conditions which prevail for 270 days each year, make it necessary to minimize the effects of the contaminants which remain after engineering controls have done the best possible job.

In order to ascertain the average wind currents, the Air Pollution Control District's meteorology department now collects wind data from over 30 stations. This study, requiring at least 3 years to complete, will be used in conjunction with the comprehensive data already obtained from air sampling and source analyses programs.

Over 6,000 tons of waste material must be disposed of daily in Los Angeles by industry, commerce, and private residents. Although improved equipment and techniques have materially reduced smoke emissions from the first two sources, domestic rubbish contributes an ever-increasing amount of atmospheric pollution. Research should be directed to the field of combustion and to the means of conserving valuable materials in rubbish. Composting certain wastes for use as fertilizer or recovery of the heat value should be aggressively explored. New ways for using and disposing of rubbish

would be a boon to every metropolitan area and a great step forward in reducing air pollution from millions of incinerators.

The physiological effects of air pollution is a virtually untouched field. Many living in industrial areas believe their health is being impaired. Controlled experiments are extremely difficult because of the relatively low concentrations of most contaminants. Where submicron dusts or fumes are involved, fundamental research has progressed to a point where some experiments can be undertaken, but years of research will be required for even preliminary answers.

The control of gasoline vapor is another major problem. Despite the amount now kept out of the air in Los Angeles, about 500 to 700 tons a day are still escaping from the processing and distribution of gasoline. Methods to correct losses should be pressed forward. Refinery processes, evaporation losses, and transfers of gasoline from tank to tank are the main control points.

The release of hydrocarbons from automobiles requires detailed study. While some preliminary research has been started in Los An-

geles, much remains to be done. Evidence indicates that the exhaust from vehicles may be an item for control measures. Before any action can be taken, the contribution to general air pollution of a community, or to the street-level nuisance effect, must be clearly demonstrated.

Other projects such as the reduction of sulfur dioxide from coal- and oil-burning equipment, improved fly ash collectors and basic studies on filter media, analytical methods, and instrumentation are being undertaken by many research organizations. It is recognized that these studies will assist the control efforts of industry and government, but it is short-sighted to ignore problems which appear on the horizons of our growing communities.

Increased populations, technologic changes in industry, and the use of new products generate new community problems before the old ones are solved. A striking example in the field of air pollution control lies in the fact that techniques are not available for full protection to a community against potential radiation hazards, which could develop from the wide use of radioactive materials in industrial processes.

Public Health Service Staff Announcements

Dr. H. Van Zile Hyde, chief of the Division of International Health, Public Health Service, has been appointed by the President to serve as United States representative on the Executive Board of the World Health Organization. His appointment was confirmed by the Senate on July 20, 1953. Dr. Hyde previously held the position of United States representative from May 1948 to May 1952, which encompassed the first two terms of the United States' membership on the Board. In May 1953, the United States was elected by the Sixth World Health Assembly to its third term.

Dr. Hyde, for several years active in international health affairs, most recently as director of the health and sanitation staff, Technical Cooperation Administration, has been chief of the Division of International Health since March 1, 1953. This division, transferred from the Office of the Surgeon General to the Bureau of State Services on April 1, 1953, is also responsible for recruitment of personnel for the public health missions of foreign assistance programs, technical supervision of their work, and placement of foreign personnel for professional training.

Dr. Frederick J. Brady, international health representative in the Division of International Health, has been appointed by the President to serve as alternate representative on the WHO Executive Board.

Dr. John R. McGibony, chief of the Division of Medical and Hospital Resources of the Public Health Service since 1949, has been appointed professor of medical and hospital administration and director of the course in hospital administration in the Graduate School of Public Health of the University of Pittsburgh. A commissioned officer of the Public Health Service since 1936, Dr. McGibony contributed to the planning and development of the Hospital Survey and Construction Program. In 1946 he became assistant chief of the Division of Hospital Facilities. Prior to this appointment, he served first as hospital administrator and then as director of health for the Bureau of Indian Affairs, Department of the Interior. In recent years, Dr. McGibony was also hospital consultant to the National Security Resources Board and the Federal Civil Defense Administration.

The Teaching-Learning Situation

By GORDON W. ALLPORT, Ph.D.

Principles derived from the psychology of learning and of human relations can be applied to medical teaching. A widely known Harvard psychologist tells coordinators of cancer teaching about the need for teacher enthusiasm for the subject being taught . . . the classroom lecture and its participants . . . the student's growing-edge and his ego-involvement . . . and possible methods for imparting the skills needed to reduce patient anxiety.

IN GENERAL, the rules for effective teaching and retentive learning that I offer here somewhat dogmatically are as valid in the field of medical education as in the field of liberal arts. For whether as teachers our aim is to communicate the principles of cancer, of psychology, or of English composition, the basic rules are essentially identical.

The first requirement for successful teaching is too obvious to require explanation: The teacher must himself possess expert and up-to-date knowledge of his field. The only comment on rule number 1 is that while it is a necessary principle of good teaching, it is by no means a sufficient principle. Plenty of men with expert knowledge are failures as teachers.

The second requirement reaches into the domain of temperament. A good teacher needs to have a contagious enthusiasm for his subject, by which I mean he should be intellectually noisy. Not that he must be loud in voice or garrulous. His manner may be soft or bold,

his voice quiet or loud, his bearing assertive or genteel. But there must be a tonicity of interest and a pressure to communicate that convince the student that something of vital importance is gripping the teacher's mind.

For teachers who feel timid and unsure in meeting a class, there is a reassuring principle. Be yourself. If you know your subject and are reasonably prepared, then forget all about your appearance, even your tics, your stammer, your mannerisms, and your neurosis. Teaching is not acting; it is not oratory; it is not salesmanship. Unlike these vocations it does not depend on superficial address. It is a deeper process of communication. It can proceed successfully, no matter how unfavored the teacher is by nature, provided he wants to convey his more adequate information about a subject to a student who wishes to learn.

The Student's Growing-Edge

So much for the teacher's own equipment and personality. Look now at the interaction process itself, at the devices the teacher may use to enhance the success of his efforts.

I emphasize the need for any teacher to know where the student stands now in his knowledge. The target should always be the growing-edge of the student. It is true that at a given time

Dr. Allport, member of the National Commission for UNESCO and formerly editor of the Journal of Abnormal and Social Psychology, is author of Personality: A Psychological Interpretation and other books.

no two students have precisely the same growing-edge. One has more knowledge than another; one has read the assigned textbook, another has not. The identical point made by a teacher may strike fire in one student and leave another cold. Even so, a medical teacher—any teacher—can acquaint himself with the previous average preparation of the students, assuming neither too much nor too little knowledge on their part. If in doubt, the instructor can always inquire of the group what the stage of their training may be. Three minutes taken at the beginning of the hour for this purpose are well invested. Unless I am mistaken this principle needs to be observed especially in medical education where specialist teachers are likely to be unacquainted with the background in fundamentals that the student brings.

The principle just mentioned does not, of course, preclude the need for review. To spend the next 5 minutes of the hour in reviewing the fundamentals of the subject is like laying fresh cement to hold the new bricks in place.

Talking reaches only the ear. The blackboard reaches both eye and ear. Why not give the student two chances for his money rather than one? For the comprehension of more difficult material investigations have shown that visual reception is superior to auditory. While not all audio-visual aids are effective, the teacher's duty is to keep abreast with audio-visual and demonstrational aids so they may be used if in his judgment they promise to be effective.

Return, for a moment, to the student's growing-edge. Those who are just entering into the study of a special topic sometimes complain of the tendency of some instructors to nourish their own edge rather than the student's. They cite the habit of some teachers who devote the instructional hour to some current article in a technical medical journal dealing with a small point of interest to the teacher but far too specialized for the student's current need. Even when the citation is accompanied by wholesome enthusiasm and excitement on the part of the teacher, it is basically a self-centered and not a student-centered device, unless, as occasionally happens, the journal article falls at the student's growing-edge. On the whole, the device seems

more suitable for the instruction of interns and staff than for younger medical students. The principle, being stressed here, says: Let the elementary student's present need, not the instructor's current enthusiasms, channel the instruction.

A synapse, we are told, may stop conducting if overcrowded by nerve impulses. So too may a student's mind. A common type of overcrowding is the recital by the instructor of endless statistics. They cannot be understood, certainly not retained. Round figures, in most cases, will fix the point in mind with sufficient accuracy. Learning will be aided if the amount of material to be assimilated within the hour is kept to manageable proportions, and the unessentials are trimmed out.

Invariably students praise instructors who know how to organize the material well. It is safest for most of us deliberately to follow a prepared outline. A medical student told me that he thought the subject of cancer had a natural, intrinsic, organization of its own. Whether he was right, or was unconsciously reflecting superior teaching, you can judge better than I.

Recent research has—broadly speaking—put the lecture on the defensive as a pedagogical method. Its potential virtues, however, are considerable. It can give perspective, inspire enthusiasm, and summarize much material from varied sources. But it can only do so if it is orderly in arrangement and distinguishes the highlights of a subject from lowlights.

There is no single method of employing a textbook to best advantage. Some effective teaching follows the text closely, never of course with monotone repetition, but with the purpose of underscoring important points, and made vivid through added example and personal experience. It seems a safe rule that the instructor should never disregard completely the assigned reading. The student is expected to integrate reading with oral teaching; it is only fair for the teacher to give what aid he can. Such integration is especially important for the beginning student.

Student Participation

Some of the principles may seem little more than pedagogical routine. Yet they have a

bearing on the most important of all factors in the teaching-learning situation—the motivation of the student to learn. Granted that a medical student is thoroughly committed to his chosen profession and suitably goaded by poverty, by zeal, or by spouse to pass the endless array of requirements, there is still the fact that one medical subject may seem to him dull and lifeless, and another may inspire him to put forth maximum learning effort. What principle is the teacher of the first subject failing to observe? Why is his subject as he presents it dull and dead?

In all probability he is failing to maximize the student's opportunity for participation. A student learns more by doing than by listening. The educational philosophy of John Dewey is certainly correct in stressing this generalization. So too is the Chinese adage:

When I hear it I forget it
When I see it I remember it
When I do it I know it

The Role of Lectures

Lectures have their place. They can properly supplement participation, or, to a greater extent than most lecturers realize, they can evoke it. When the student asks a question, he is participating. When he is asked to look up the answer and report back to the class at the next hour, he is participating still more. He is less likely to forget the information than if the instructor, like an oracle, pronounces the answer. Such participation can be woven into a lecture, though available time limits its use. When a diagnosis is called for, let the student try his hand at it before the instructor makes his pronouncement. And—very important—give the student plenty of time to reach his decision, so that he may know that his best effort at the task has succeeded or failed. I wish that all teachers of all subjects would obey the rule to give the student time. It is a common failing, especially on the part of the insecure teacher, to choke off a student wrestling with a problem, and himself to supply the answer before the gains of participation have been achieved.

Participation is a large subject. It covers student questions, recitations, prepared papers, practice diagnoses, laboratory work, case pres-

entation, and much else besides. A particularly effective method for participant study is the assignment of questions in advance for a coming examination or for the next day's class work. In the latter event it is well for the student to correct his own paper, spotting his own errors and thus cultivating his own growing-edge.

The law of participation has, of course, a mundane practical side. The possibility of participation is normally in inverse ratio to the size of the group being taught. Medical schools surely know this fact; else it would be difficult to explain and justify the severe restrictions on the size of entering classes. In teaching the radiological aspects of cancer, for example, one can do with a cluster of five or six students what one cannot do with thirty. But we should not take refuge in this easy alibi. Even in a large lecture class alert teachers can often discover small ways to elicit participation. Instead of droning on for an hour without interruption the teacher can have his listeners in their seats perform small experiments or write down what they think are the right answers to certain questions which later will be answered by the lecturer. There are more devices to elicit participation than we teachers realize.

Ego-Involvement

But participation has deeper psychological significance. Who participates? It is surely not the hands and voice of the student. It is, if I may introduce the term, his ego. In recent years psychologists have had much to say concerning ego-involvement. In one sense ego-involvement is basic to all learning; in another limited sense, it impedes it. In the broad sense, favorable to learning, we may say ego-involvement is more or less identical with interest. By a principle of subsidiation a student will learn to absorb and organize material that is consonant with his own interest system. The instructor will elicit this form of ego-involvement if he is successfully aiming at the present growing-edge of the student, and if by his own example he conveys enthusiasm for the subject.

In a more restricted sense, ego-involvement means self-esteem. Even a medical student—

burdened and misshapen as he is by poverty and prescriptions—is strictly normal in respect to his human sensibilities. For him, as for all learners, praise is a great incentive. If he does a good job he wants to know it. Next time he will deliver an even better performance.

But if praise is favorable to the effective acquisition of knowledge and skill, ridicule and embarrassment are not. Here we come to a curiously sadistic teaching-learning situation that has nothing to be said for it. Why some teachers like to pounce on a given student without warning, and with fierce aggression demand that he produce the precise point that the teacher has in mind at the penalty of being ridiculed, is a question in the psychopathology of teachers that we shall not explore. The principle in question can be summarized by saying that to raise the student's self-esteem is a mark of good teaching; to lower it is (with very rare exceptions) a mark of bad teaching.

Reducing Patient Anxiety

There is one important special skill that every medical student—especially those dealing with cancer patients—must acquire. How to learn this skill poses a major problem for the teaching-learning situation. The alleviation of the patient's anxiety is one ability that certainly cannot be taught by lectures. How then may a student learn it? Unless I am badly mistaken, medical education in general and cancer education in particular pay too little attention to this difficult pedagogical problem.

Recently I reviewed data collected in connection with a project in cancer research. The problem concerned reasons why women with breast lesions had delayed in seeking treatment even after they suspected the nature of their difficulty. I am not prepared to offer a statistical report of this research, but the large number of cases where the physicians themselves seemed at fault was disturbing to me. They aroused so much anxiety that the patient repressed the matter, disbelieved the doctor, or took refuge in some other form of psychological defense. Disturbing too were the cases where patients reported callous acts on the part of doctors. In one case, following an examination, three physicians held their consul-

tation in the corner of the woman's hospital room; then left the building without speaking to her. For days she lay in agonized doubt, without knowledge of her condition and without the clearly indicated supportive psychotherapy.

Most experienced physicians, I know, behave very differently. Many make it their first duty to allay anxiety to the best of their ability. I am not here presuming to raise the disputed question as to how much a patient should be told about his condition. My point is merely that however much is told it can be told so as to relieve anxiety to the maximum degree possible.

How is the reassuring manner to be learned? What approaches may be used in breaking bad news? For that matter, how can any physician in any kind of case help lift the patient over his psychological hurdles? A young medical student—especially one not temperamentally gifted in this regard—has much to learn. While I am not wise enough to solve this difficult problem, I can offer two teaching devices that have been successful in modern attempts to give instruction in the field of human relations. Possibly you may see merit in one or both of them for the teaching of doctor-patient relations.

Apprenticeship

The first device is an extension of the ancient method of apprenticeship, aided by modern technology. Perhaps as an understudy to a skillful doctor, both in his technical work and in his human relationships, a student would be given a model from which to pattern his own efforts. But there are limitations to apprenticeship. Can a medical student accompany a physician who is about to tell a patient that he will die of carcinoma of the liver? Modern technical developments include the possibility of hidden recordings, also of using one-way screens made of molecular chromium glass. Granted that these devices are not adapted to home calls, is there the possibility that they can be employed effectively in hospitals for the teaching of doctor-patient relations, not only when matters of life and death are involved but in other situations calling for skilled efforts at anxiety-reduction?

I realize that this suggestion, made most tentatively, raises problems of medical ethics. Does it differ significantly from ward rounds, attendance at operations, or other occasions where medical students are introduced to intimate personal relationships? In certain psychological laboratories the ethical problem of using hidden recordings has been met in the following way. The subject (patient) is later told that a recording was made for teaching purposes. If he will permit it to be so used the investigator will be grateful; but if he prefers that it not be so used the recording is straightway destroyed. The one-way screen does not, of course, permit this ethical safeguard. But it too may have its limited uses, for example, in cases where a patient gives advance consent.

Psychodrama

The second suggestion raises no problems of ethics. It concerns the possible employment of role-playing in cancer education. Let one young medic play the part of a patient who is to be told that he has an operable malignant growth. Let another play the role of his physician. The situation can be specified somewhat more fully. The patient, let us say, is 45 years old, father of a family, worried about expenses, as well as about the possible outcome. The physician in his own mind is not too certain that the outcome will be favorable but like all physicians he holds the optimistic bias. Innumerable situations of this sort can be invented to start off the psychodrama. When the play has run its course, there can be class discussion and criticism of the "physician's" behavior. The class instructor may have suggestions to make. The scene can be played again until it meets general approval. The

actors can, and should, reverse their roles. And every student in the class can, and should, have extended practice.

This method can helpfully expand and deepen the experience the student now gets through his attendance at clinics. Situations he has observed can be more fully explored through acting them out. Hypothetical situations that anticipate his own later responsibilities can be used. The process of role-playing, awkward as it is for the tyro, can in time confer upon him flexibility in manner and an invaluable understanding of the patient's point of view.

It is true that teachers who would employ this method themselves need training in its use. There are experts in psychodrama who would, if asked, turn their attention to the field of doctor-patient relations, and if it seems desirable, conduct a workshop in the technique for the benefit of interested medical teachers.

It does no good, I feel certain, to tell a medical student that he should allay anxiety, that he should be sincere, reassuring, quiet, calm, confident. He needs concrete example and he needs practice in human relations. I hope that in the future medical, especially cancer, education will develop methods to train in these skills, and thus rub off in advance some of the rough edges of young practitioners.

Apart from the problem of alleviating anxiety all of the features of the teaching-learning situation that I have mentioned are common pedagogical property. The principles I have stated with such brevity derive from the psychology of learning and from the psychology of human relations. Experience has found them to be sound guides to teaching. I hope that some of them may have suggestive value for you.

The Development and Evaluation Of Cancer Diagnostic Tests

By JOHN E. DUNN, Jr., M.D., and SAMUEL W. GREENHOUSE

ANY ATTEMPT to bring the majority of human cancer cases to clinical recognition in a curative stage, at least until new therapeutic methods are established, involves the ability to recognize the disease in an asymptomatic individual. Searching the general population for unsuspected cancer using clinical procedures has been explored through cancer detection centers, but has been found to be impractical because of the inadequate capacity of such facilities and the relatively high cost per examinee.

The need for a procedure to indicate the existence of unsuspected cancer has led to many attempts over the years to devise a laboratory procedure that would show whether or not an individual is harboring a cancer. These procedures have usually taken the form of chemical, biological, physical, or immunological measurements on readily available human materials such as blood, urine, and exudates, or of skin tests.

A priori it can be said that the possibility of developing such a diagnostic test for a disease is dependent on unique and specific substances produced by or as a result of the disease, which can be measured by laboratory procedures; or by quantitative changes in normal body con-

Dr. Dunn directed the field investigations program of the control branch, National Cancer Institute, National Institutes of Health, Public Health Service, from 1948 until his present assignment to the California Department of Public Health at Berkeley. Mr. Greenhouse is a statistician in the biometrics section of the technical services branch, National Cancer Institute.

Public Health

MONOGRAPH

No. 12

The accompanying article discusses the principal findings presented in Public Health Monograph No. 12, published concurrently with this issue of Public Health Reports. These papers, by authors from the Medical College of Alabama, Tufts College Medical School, the Schools of Medicine of the Universities of Washington, Tennessee, and Kansas, and the Research Laboratory of the Jewish Memorial Hospital, Roxbury, Mass., were assembled by the National Cancer Institute, National Institutes of Health, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Evaluation of cancer diagnostic tests. Public Health Monograph No. 12 (Public Health Service Publication No. 275). U. S. Government Printing Office, Washington, 1953. Price 30 cents.

stituents that are more or less uniquely associated with a specific disease. Various immunological tests for acute infectious diseases are classical examples of the former, and the glycosuria associated with diabetes mellitus, of the latter. Unfortunately, cancer research has not as yet demonstrated well-established qualitative changes, either in cancer tissue as such, or in the host organism supporting the cancerous growth. Quantitative changes are known to occur in cancer tissue as compared to the corresponding normal tissue. Also, there are quantitative changes in the host, but these changes are not uniquely associated with cancer. The question, then, becomes one of whether a proposed diagnostic procedure based on empirical observation is perhaps founded on a mechanism that is yet unknown or not fully elucidated in the mass of cancer research knowledge, or whether the known quantitative host changes, singly or in combination, might not serve as a means of distinguishing cancerous from normal individuals and from those with other diseases.

In general, attempts to find a diagnostic test for cancer have been met with an attitude of pessimism since the body of cancer research knowledge has apparently not yet established a firm basis for development of such a test. On the other hand, those faced with the urgent demand that something be accomplished now to reduce human cancer mortality are confronted with the necessity of taking calculated risks.

In 1948, several university groups indicated an interest in exploring proposed cancer diagnostic tests to determine their usefulness by requesting grant funds from the National Cancer Institute. These projects were approved by the National Advisory Cancer Council and a loosely coordinated program was developed in which the five university groups looked to the cancer control branch of the National Cancer Institute for liaison and technical assistance in the analysis of data. The five groups carrying on this work are under the direction of:

Dr. Stuart W. Lippincott, professor of pathology, University of Washington Medical School, Seattle, Wash.

Dr. F. Homburger, director, cancer research and cancer control units, department of surgery, Tufts College Medical School, Boston, Mass.

Dr. J. K. Cline, chief, cancer research department,

Medical College of Alabama, University of Alabama, Birmingham, Ala.

Dr. Douglas H. Sprunt, director, Institute of Pathology, University of Tennessee Medical School, Memphis, Tenn.

Dr. Robert E. Stowell, professor of pathology and oncology, University of Kansas Medical Center, School of Medicine, Kansas City, Kans.

The principal aims of this program were:

1. To determine whether any of the many diagnostic tests for cancer proposed in the past meet the original claims made for them by their developers when carefully evaluated by another laboratory.

2. To follow up any leads in basic biological, chemical, or biochemical research bearing on the diagnostic problem and possibly leading to the development of a test.

Additional purposes served by this program, purposes that were made apparent only after the program had been under way, were:

1. To provide a much needed statistical methodology in order to unify and make comparable different evaluations of the same test and also evaluations of different tests.

2. To utilize the experience and facilities of the participating groups to evaluate tests developed currently.

3. To obtain leads meriting further investigation resulting from the analysis of data collected by the various groups.

The purpose of this paper is to describe briefly the accomplishments of this program in fulfilling these aims. Much of what follows has already been said or reported elsewhere; the remainder is new.

Methodology

In order to evaluate the practical usefulness of cancer diagnostic tests, the performance requirements for a useful test must first be decided upon. Since the primary objective was a test that would indicate the probability of unsuspected cancer, the requirements of a case-finding or general population screening test were given primary consideration. Criteria were proposed and a statistical method for analyzing data on the basis of these criteria was developed (1). It was realized that a test would have other uses as well, such as for differential diagnosis in a diseased individual. Evaluation studies, therefore, included patients with

diseases other than cancer. However, it appeared reasonable that a test that would not distinguish satisfactorily between individuals apparently free of disease and those with cancer could not distinguish the latter from other diseased individuals.

Most of the general tests proposed to detect the presence of cancer are blood tests, based on the principle that some factor, for example, the blood proteins, enzymes, or an immunological agent capable of reacting with an antigen, appear in the blood serums of cancerous individuals and either are lacking or are quantitatively different from that in the blood serums of normal individuals. Measurement of this factor in a group of normal individuals and in a group of individuals with known cancer, in most cases, gives rise to a continuous variable more or less symmetrically distributed about a modal value which differs in the two groups. To make this process a diagnostic procedure it is necessary to select one value of the variable, the so-called critical value, to serve as the dividing point for future tests. If a person's measurement, say, exceeds the critical point, he would be classified as positive; if it falls below, he would be called negative. (In the past we have stressed the fact that no single test can do more than result in these designations and only provides evidence that a person called positive has some probability of having the disease. It is only after a person so classified has undergone clinical study that cancer can be diagnosed.) Once the critical point has been selected for any set of data, it becomes possible to refer to two measures inherent in the test, namely, the proportion of false negatives (sensitivity) and the proportion of false positives (specificity). These measures are completely dependent upon the choice of critical value and, in fact, vary as the critical point varies. We illustrate this in the following tabulation, based on an evaluation of the Huggins iodoacetate index by Homburger and associates (2).

The implications in analyzing evaluations of diagnostic tests are clear. Contrary to past experience, an evaluation must not adhere blindly to the same critical value reported by the originator. The investigator must find the critical value that will give either the same specificity or sensitivity as that obtained by the originator and then compare the remaining measure. For example, if, from the previous table, one were to advocate the Huggins iodoacetate index because it gave 24 percent false negatives for 20 percent false positives, then the purpose of an evaluation is to confirm that this procedure gets 24 percent false negatives for 20 percent false positives. The investigator evaluating the test collects his own data and attempts to reproduce the biological and chemical aspects of the procedure as carefully as he can. Often biases exist but, even if they did not, characteristics of the distribution, such as the critical point giving 20 percent false positives, are subject to sampling variation. (Our experience has been that consciously or unconsciously the investigator makes some modification in techniques and that sampling variation is small compared to these biases.) Thus, if the investigator were to seek out the value 6.8 as his critical point because the originator used this value, he might find 35 percent false negatives and 15 percent false positives or any other proportions. On this basis he would conclude the original report has not been verified. What, in fact, he should do is find the critical value giving him, say, 20 percent false positives and then determine the percent of false negatives for this critical point. If this turns out close to 24 percent or less, the evaluation confirms the original report; if it is considerably higher, then the investigator rejects this test based on the way he performed it.

The two essential points in an evaluation program are, therefore:

1. Two sensitivity measures must be compared where each is obtained for a fixed specificity (or the converse).
2. The critical value to be found in determining the sensitivity is itself determined by the given specificity.

Costs of examination and incidence of cancer are such that it was reasoned no screening program for cancer could tolerate more than 10

Critical value:	Percent false positives	Percent false negatives
5.3-----	5	55
5.9-----	10	43
6.8-----	20	24
7.8-----	40	17
8.6-----	60	9

percent false negatives for at most 5 percent false positives. These criteria need not be followed if one searches for a diagnostic test to be used for other purposes, such as differential diagnosis.

Evaluation of Tests

A considerable number of reports have thus far been published as a result of the cancer diagnostic test evaluation program. A list of these reports, classified according to type of substance being measured, appears as an appendix to the most recent publication, a monographic collection appearing as *Evaluation of Cancer Diagnostic Tests*, Public Health Monograph No. 12. In addition to tests on which reports have been published, several tests were evaluated by the various groups at the request of the National Cancer Institute and other institutions. These represented tests being developed currently and for which no large-scale evaluation was necessary in order to reject them. On the other hand, several tests announced in the last 5 years were evaluated fully and reports were published.

Unfortunately, as reference to these publications will show, none of the procedures evaluated has been judged capable of discriminating between individuals with cancer and those without cancer to any reasonably high degree. For a cost of 5 percent false positives among presumably normal, healthy individuals, these tests, as evaluated, detected as positive from 10 percent to about 75 percent of known cancer patients, with the majority ranging from 40 percent to 60 percent. For the most part, these tests also found as positive from 25 percent to 50 percent of patients with diseases other than cancer. But more serious from the point of view of screening is the fact that these tests gave rather poor results among known cancer patients with well-established disease. Presumably, if groups of individuals with very early cancer were available, these tests would detect as positive still smaller proportions.

Evaluation and Developmental Findings

Although results have been negative in the search for a general test for cancer, all of the

participating groups are continuing in some developmental field of their own. In some cases, investigation is being made into the diagnosis of cancers of specific sites; in others, work is being continued on those general tests which a group thought promising. Every group is doing research into the development of its own procedure, both on the laboratory and clinical level.

All participants have concluded from their evaluations thus far that much has yet to be learned about the relationships to the cancer process of those factors which these tests purport to measure. The awareness and the need of a greater understanding of the effects of this process on the biochemistry of the individual are evident in the report on the Proceedings of the First Conference on Cancer Diagnostic Tests (3). The very purpose of this conference, sponsored by the National Cancer Institute, was that "... further developmental research in the cancer diagnostic test field should be stimulated."

It would appear that one reason these tests have failed is the lack of specificity in the factors assumed to be changed by cancer. Generally, these factors seem to be affected by many disease processes. In fact, they are found to vary among normal individuals. This raises some interesting questions concerning the concept of a diagnostic test (see paper by Toenies in reference 3). Given that normal individuals really differ with respect to a given factor, does the single individual's test value vary with respect to time or does it remain relatively stable? If it does change with time is this variation random around some true value and, if so, how does it compare with the variation among individuals? If it is relatively small then obviously if an individual's test value begins to increase progressively over time, he should be suspect even if his test values are not above the critical point (assuming cancer values are on the average larger than normal values). However, before such serial testing on an individual basis can be of use, much data must be gathered to answer the above questions on variation.

A start in this direction was made by one laboratory, which was able to obtain more than one blood specimen on normal persons over a

period of a year. We illustrate some of these ideas referring to the evaluation, by this laboratory, of the least coagulable protein test proposed by Huggins (4). With respect to this test, the values of 137 normal individuals ranged from 1.10 to 1.91 with a variance, $\sigma^2=0.0139$. The variation among individuals, measured by the variance, can be considered to be made up of three components: variation among true individual values, σ_{Ind}^2 , variation between specimens from the same individual when specimens are taken over a period of time, σ_{sp}^2 , and variation due to the reproducibility, or measurement error, of the technique, σ_m^2 . Estimates of these components were as follows: $\sigma_{Ind}^2=0.0075$, $\sigma_{sp}^2=0.0022$, $\sigma_m^2=0.0035$. Variation due to specimens, σ_{sp}^2 , represents about 16 percent of the observed variation among individuals and about 30 percent of the estimated variation of true individual test values. Consider an individual with a true value of 1.3. Assuming no improvement in technique can be accomplished to reduce measurement error, 95 percent of specimens from this person should result in values ranging from

$1.3-2\sqrt{\sigma_{sp}^2+\sigma_m^2}$ to $1.3+2\sqrt{\sigma_{sp}^2+\sigma_m^2}$ or 1.15 to 1.45. Now, if this person gets cancer, his true value should begin to increase and hence his test values should eventually fall outside his normal range. When this occurs, his test should be considered positive even though no value is greater than the critical point (in this case, 1.63).

Considerations of this sort have come out of the analysis of the data gathered in the evaluation program. For two other tests, σ_{sp}^2 represented a much greater proportion of the total variation. In fact, for one test it was almost 50 percent of the total variation and exactly equal to the estimated variation of true test values. In these instances, no serial testing on an individual basis would be meaningful.

Present and Future Developments

As indicated earlier, the various laboratories that have been engaged in diagnostic test evaluation have continued investigating certain procedures that still appear to hold some promise, and are exploring developmental possibilities that have attracted their interest. The former includes further work with a serum flocculation reaction that has undergone additional development since originally reported; exploration of fluorescence phenomena observed in the blood from cancer patients; polysaccharides of serum that are augmented in cancer patients; and use of several serum protein determinations in combination. Developmental investigations by these groups include investigations into a sensitive means of detecting abnormal steroid in the blood or urine; a complement fixation test; a study of the factor responsible for liver catalase reduction in cancer; and a specific measurement of prostatic acid phosphatase. This last has been developed to the point where several laboratories are evaluating it as a means of diagnosing premetastatic prostatic cancer.

A Review of Pollenosis And the Role of Weeds

By W. C. SPAIN, M.D.

THE TERM "WEED" and the term "allergy" not only are difficult to define but are vague, indefinite, elastic, and subject to wide variations in interpretation. An agreement upon the concept of these two expressions is essential to any remarks that may be made upon them.

When does a plant become a weed? What is a weed? One's point of view would have something to do with reaching a decision. The overgrown vegetations of the tropics, rank and commonplace, become rare and pleasing exotic plants elsewhere; the goldenrod, an annoyance to the farmer, may appear as a colorful attractive flower to the urban dweller. It would seem that a plant becomes a weed when its nuisance value outweighs its esthetic or economic worth to man; when its lustiness and vigor, despite its beauty of form or flower, permit it to crowd out more delicate and more desirable plants; or when its noxious qualities make it a threat to the well-being of man and animal. On the basis of their being specific hazards to his own health, the allergic individual is inclined to group as weeds many additional plants which actually are of value in the general economy and are attractive and harmless to the majority of the population, but to him are decidedly disturbing.

The person suffering from an allergic malady is a peculiar individual, due largely to the fact

that his symptoms are caused usually by a maladjustment to his physical environment rather than by any bacterial invasion of his body by infection. His ailments result from exposure to commonplace substances with which all persons are equally in contact. Although exposed to these substances to a degree no greater than are other members of the general population, his symptoms are prompt, severe, incapacitating, and place in the role of a major offender with great etiologic importance such an ordinary and usually harmless agent as the ever-present weed.

Heredity a Factor

This tendency to react with marked discomfort to his surroundings is hereditary. It is a family trait transmissible from a member of one generation to that of another, apparently governed according to the laws of dominance that Gregor Mendel found operative in his study of the transmission of traits of the sweet pea. It is important to remember that the feature which is inherited is the capacity of the allergic individual's tissue cells to become extremely irritated or sensitized in a specific manner. The well-developed clinical allergic complaint itself is not inherited, its form being influenced greatly by the exposures and contacts in the individual's environment. Hay fever, rhinitis, bronchial asthma, bronchitis, and dermatitis (urticaria and eczema) are examples of allergic maladies caused by this cell sensitization. The tendency to an allergic condition may be manifested in a parent as hay fever, in the child as an entirely different ailment such as bronchial asthma.

The Role of Phagocytosis

Nature has provided a clearing mechanism for protecting man from the irritation of foreign substances passing into his system by absorption through the respiratory and gastrointestinal tracts and the skin. These foreign substances, naturally and normally present, are in the air we breathe as are pollens, dusts, animal danders; in the food we eat; in plant resins with which the intact skin comes into contact. Upon being absorbed into the body, such sub-

Dr. Spain is professor of clinical medicine at the Post Graduate Medical School, New York University, and attending physician and director of the division of allergy, medical department, University Hospital. He is a member of the editorial board of the Journal of Allergy. This paper is condensed from an original lecture given by the author at the weed control conference conducted by the New Jersey State Department of Health at Rutgers University on April 8, 1953.

stances are attacked by tissue cells especially equipped for the purpose of neutralizing and disposing of any invading foreign material.

This process is completed without harm to the normal individual or his tissue cells, and without apparent detrimental after-effects such as the development of allergic symptoms. In 10 percent of the population, however, this special protective mechanism or phagocytosis does not end with this normal activity of disposing of foreign matter. The mechanism, often through hereditary influences, extends beyond this, becoming exaggerated and overcompensating. Enormous increases in the number of the defensive tissue cells or a great enhancement of their protective activities, or both, are stimulated by their contacts with the foreign substances. Such cells are equipped to produce a prompt and vigorous attack upon the reinvading foreign substance. This activity is responsible for the release of toxic materials which cause the severe, often incapacitating allergic symptoms.

Individuals whose tissue cells are thus sensitized to intense activity upon exposure and re-exposure to foreign substances are termed allergic, and their symptoms may assume a variety of forms such as those of hay fever, bronchial asthma, or of allergy of the gastrointestinal tract or skin, depending upon the body area in which occurs the greatest degree of sensitized cell activity. Urban dwellers and rural workers, child and adult of all races are affected. The foreign materials, the causative agents, are many and varied, but are usually airborne as pollens, dusts, or ingestible substances such as foods and drugs.

Airborne Pollen

Of major importance are airborne plant pollens drawn into the respiratory tract in the inhaled air. The heavy, sticky type of pollen which tends to be immobile unless transported by the bodies and wings of visiting insects and bees is rarely the cause of hay fever. The colorful, attractive, often scented blossoms such as of the rose, the daisy, or goldenrod, designed to lure these carrying agents, are harmless unless cut and brought indoors where they dry, allowing their pollens to permeate the closely con-

fined atmosphere of the house. The airborne pollens of the plants with inconspicuous, less noticeable blossoms are the usual cause of hay fever. Produced in tremendous excess, buoyant and widespread, these pollens are responsible for the distress of thousands of persons with hay fever and with bronchial asthma.

Not all types of airborne pollen are hay fever and asthma producers. Over the past four decades it has been the goal, seemingly impossible, of allergist and of botanist to discover in all the wealth of vegetation the particular offenders, and to identify the plants whose pollens produce allergic symptoms. In this the investigators were aided by two tremendously important facts; the first, that the skin cells of the allergic patient share the sensitization found in other types of tissue cells; and the second, well known to you, that there has been established by nature a reliable, dependable schedule of pollination characteristic of each plant, a schedule influenced but slightly by climatic or weather variations.

The Skin Test and Pollen Count

The skin test is the great diagnostic aid which enables identification of the patient with hay fever and also determines the specific, exact pollen causes important in his case. Upon exposing the cells of the skin by puncture or scarification procedures to minute carefully estimated amounts of extracts of the various suspected pollens, characteristic changes will occur, but only at those sites tested with the pollens to which the patient's cells are sensitive. Within a few minutes itching, flushing, and swelling of the skin will occur, with the development at the test site of a wheal or small hive, which persists for 15 to 20 minutes, then disappears. This test is very specific and delicate. It enables the investigator not only to identify the particular offending pollens, but also to determine the degree of sensitiveness present in the individual to each specifically offending pollen, a matter of great variability from patient to patient, and from pollen to pollen.

Well known to the patient suffering from a pollen allergy is the period within which his symptoms occur. The seasonal limits of onset

and offset of his discomforts are relatively constant from year to year, provided he continues to be in the same environment. By comparing the period of suffering with the pollination period of various plants producing airborne pollen, the investigator is enabled to narrow the list of possible causes in each patient's problem. The individual with hay fever occurring from mid-August to October is immediately suspected of being a victim of ragweed pollen, since its pollination period coincides with the patient's time of discomfort.

Additional useful information regarding pollen allergy may be obtained by comparing the patient's daily fluctuations in the degree of severity of his symptoms with the daily census of his specifically disturbing pollen as influenced by variations in weather conditions. A daily count of the pollen trapped upon an adhesive coated slide, exposed for constant periods, will provide the information upon the rate of pollen production. Thanks to their characteristic appearance microscopically, a classification can be made of those pollens most prevalent. Ragweed pollen has been made the object of special study. The New York State Department of Health has thus been able to determine areas in the Adirondack Mountains relatively free of this weed, and has prepared a valuable list of these for ragweed sufferers (1). New Jersey (2) and the city of Detroit (3) sponsor active pollen surveys, and according to information supplied by the division of laboratories and research, New York State Department of Health, New Hampshire and Maine also conduct these surveys.

The lists of weeds and plants which cause hay fever are known through the highly successful efforts and zealous cooperation of the botanist. Field studies and pollen surveys, the collection of pollen from suspected plants, and its subsequent testing by the allergist upon pollen victims has yielded an evergrowing mass of information. Throughout the years important data has been collected in all areas of the United States, the Central and South American Republics, England, and other European countries. Two of the most valuable reference volumes upon the hay fever producing plants of the United States are that of Wodehouse (4), and Durham (5).

Three Seasonal Groups

In the Northeastern area of the United States the dates of pollination of the important hay fever and asthma producing plants permit a sharp division of the pollen victims into three groups. In the first are those whose symptoms occur between mid-March and June first. No weed is a culprit although many tree pollen victims in this group are ready to stigmatize as weeds the real sources of their discomfort, which are the ash, beech, birch, elm, oak, hickory, paper mulberry, and poplar. The pollen of the alder and of the swamp sedges occasionally produces symptoms.

In the second group, the symptoms persist from mid-May to mid-July. English plantain (*Plantago lanceolata*) is a weed of much importance here, with sorrel (*Rumex acetosella*) of lesser importance. Of greater moment than these weeds, however, is the family of grasses—timothy, orchard, oat, rye, redtop, junc, bermuda, sweet vernal, velvet. Roses, since insect pollinated, are innocuous unless cut and kept indoors. The term "rose cold" is, therefore, an incorrect designation for the summer type of hay fever.

In the third group of patients the symptoms occur from mid-August to frost, and it is here that the weed asserts its importance. The ragweeds, giant and dwarf (*Ambrosia trifida* and *elatoria*), are the chiefs of them all, having the dubious reputation of being the cause of more suffering than all other pollens combined. Not only does the discomfort they produce involve a greater number of victims, but the suffering is more intense in degree and occurs at a time of the year, at the threshold of autumn, when secondary, complicating bronchial and sinus diseases are encouraged to appear. It has been estimated that one-third of all untreated ragweed hay fever sufferers eventually develop bronchial asthma, a much more serious and disabling disease. Of lesser importance than ragweed are cocklebur (*Xanthium*); lambsquarters (*Chenopodium*); pigweed (*Amaranthus*); mugwort (*Artemisia*); American hemp; wild rice (*Zizania*); great reed (*Phragmites*); marsh-elder (*Iva*). Usually goldenrod has on it some adherent ragweed pollen, deposited by wind from adjacent ragweed but, as stated,

goldenrod does not deserve the evil reputation it has. Its pollen, since insect borne, will cause no symptoms unless the blossoms are brought indoors.

The list of weeds which produce allergic discomfort is even greater in other areas of the United States. In the plains States, southwestern States, and the Pacific States, the most troublesome are the chenopods, thistle (*Sal-sola*), and burning bush (*Kochia*), wormwood and sagebrush (*Artemisia*).

Areas Free of Pollen

Since the distressing allergic symptoms result from actual physical contact of pollen and patient, the surest way for the patient to obtain relief is to escape to an area where the pollen producing plants particularly disturbing to him do not grow. Bermuda, Nova Scotia, the tropics, our own southwest and areas in the Rocky Mountains offer to ragweed sufferers complete freedom from hay fever. Less completely free localities are the southern tip of Florida, California, areas in the heavily wooded sections of the upper Michigan peninsula, of Maine, and of Canada and some parts of the White and of the Adirondack Mountains. The pollen surveys of the New York State Department of Health have established the relative freedom from pollen of numerous Adirondack localities (1).

Methods of Destroying the Weeds

Such escapes from pollen, however, are impractical or impossible for the majority of sufferers, who cannot be absent from their work or their families for the long intervals required. For them relief can be expected by attacking the hay fever producing weeds themselves by eradication, a slow, painful, and not very successful process, by manual removal or by cutting at the strategic moment when pollination is imminent.

Far superior are the chemical methods. New York City, according to information from its department of health, and several New Jersey communities conducted in 1946 (2) the first centrally directed ragweed control spraying program. By employing a spray of the hormone 2, 4-D, dichlorophenoxyacetic acid, it

has been possible greatly to reduce the growth of ragweed within the city limits. In proper dilutions it is reported to be selective in action in that it does not kill desirable grasses, but it is known, of course, to be lethal for vegetables and flowers (5, 6). Persistence in spraying the ragweed areas each year seems essential to prevent a return of the ragweed. Following the example of New York City, other municipalities have adopted this plan of extermination. Until all States in the ragweed zone collaborate in a determined and extensive plan, however, the hay fever victim may be somewhat benefited, but will continue to suffer, since the pollen produced by weeds many miles away can be easily transported to him by air currents.

Individual's Control of Pollen

The patient can conduct a plan of weed pollen control in his immediate environment by the installation in his bedroom or home, and in his place of business, of efficient conditioning units. Such units should filter but not chill the air, since respiratory membranes irritated and congested by pollens seem especially prone to "colds," acute respiratory infections, or sinusitis when suddenly subjected to excessively chilled air. Too, to be most effective, conditioned areas should have as their source of outside air only the conditioning apparatus, and all doors or windows should be kept closed; as little traffic as possible should be permitted into the area, since disturbing quantities of pollen may be imported upon the hair and clothing of those entering.

These measures of escape and avoidance are not altogether successful. Efforts must be made to so condition the pollen sufferer that he may continue to work and live in the pollen-containing atmosphere. This is not the time or place to discuss the therapy of hay fever—but it is pertinent to say that such treatment is based upon an attempt to increase the tolerance of the sensitized cells so that they do not react with such vigor or intensity upon exposure to the disturbing pollen. Minute, gradually increasing amounts of an aqueous extract of the specific pollen excitant are given hypodermically at weekly intervals during the period beginning 3 months before the expected season

and extending through it; or, in selected cases, larger doses administered once monthly throughout the year, though once weekly during the season, are effective (7). The use of antihistaminic drugs, of ephedrine, of soothing eye drops, of avoidance of dusts, gases, and chemical fumes contribute to the relief of the patient.

The most important step in the handling of any allergy problem is the attempt to remove the cause. This step can often be readily accomplished by the allergist if the exciting substance, identified by various tests, be an animal dander such as that of the cat or horse, causing asthma; or a food such as egg or chocolate, causing asthma or urticaria. It is impossible to accomplish if the exciting substance cannot be readily removed, being derived from widespread plant sources as in the case of an airborne pollen. Such an exciting cause is effectively reduced only at its point of origin.

President Names Dr. Keefer Health Adviser to the Secretary

Dr. Chester Scott Keefer of Brookline, Mass., took office August 12, 1953, as special assistant, for health and medical affairs, to the Secretary of Health, Education, and Welfare. His appointment by the President was confirmed by the Senate on July 31.

The position was created in the President's Reorganization Plan No. 1 of 1953 which set up the Department of Health, Education, and Welfare. Dr. Keefer will serve as top staff policy adviser to the Secretary in important external relationships of the Department with national and international bodies concerned with health and medical matters, and will, as needed, coordinate related health and medical programs within the Department.

Dr. Keefer, who received his medical training at Johns Hopkins University, presently is a member of the Executive Committee of the Division of Medical Science of the National Research Council, and chairman of the Council's Commit-

tee of Medicine. During World War II he directed United States and Allied procurement of penicillin and streptomycin, and during 1944-46 was medical administrative officer of the Committee on Medical Research of the Office of Scientific Research and Development.

Dr. Keefer has served in key positions at Johns Hopkins Hospital, Billings Hospital at the University of Chicago, and Boston City Hospital, and has served on the faculties of Harvard Medical School and at Peiping Union Medical College. He is director of the Robert Dawson Evans Memorial Hospital. He has arranged to take leave from his position as physician-in-chief at the Massachusetts Memorial Hospital and as Wade Professor of Medicine at the Boston University School of Medicine.

M. Allen Pond, chief of the Division of Engineering Resources, Public Health Service, has been detailed to assist Dr. Keefer.

Professional Education in Public Health

— A Survey of Schools of Public Health, 1950 —

By HAROLD S. DIEHL, M.D.

Report on Schools of Public Health in the United States; based on a survey of schools of public health in 1950. By Leonard S. Rosenfeld, Marjorie Gooch, and Oscar H. Levine. Public Health Service Publication No. 276. U. S. Government Printing Office, Washington, D. C., 1953. 110 pages. Price 35 cents.

• • •

SCHOOLS of public health in the United States have been organized in response to demands for personnel trained to perform the various health services which have been developed during the past century. The rapid expansion in both volume and scope of these services at each level of community life has increased the need for persons equipped to apply the accumulated knowledge in the biological and social sciences to the furtherance of community health. There is need for persons who can plan, organize, and administer health services; who can analyze and interpret trends in health conditions; who can identify questions that must be resolved for the improvement of public health activities; and who can conduct the research that provides a sound basis for

future developments. Accordingly, several universities have organized schools or departments of public health with varied organization and content of academic and field training. During their relatively short history, these universities have played a dynamic and essential role in public health progress.

Aware of the many complex problems that schools of public health face in their attempts to meet present demands for health personnel and to foresee the qualitative and quantitative demands of the future, the Association of Schools of Public Health asked the Public Health Service to make a study of the schools. The recently published Report on Schools of Public Health in the United States gives in detail the results of that study, describing the organization, staffing, educational programs, students, financial status, and needs of the schools of public health in 1950. This article represents a summarization of the major findings of the report.

Three Major Functions

The report presents data for the nine accredited schools of public health in operation in 1950 at the Universities of California, Michigan, Minnesota, North Carolina, and at Columbia University, Harvard University, the Johns Hopkins University, Tulane University, and Yale University. An accredited school of the University of Toronto and one established at the University of Pittsburgh in 1950 were not included in the study.

An accredited school is one that meets the standards adopted by the American Public

Dr. Diehl has been dean of medical sciences at the University of Minnesota since 1935. He received his medical degree there in 1918 and was appointed assistant professor of preventive medicine and public health in 1921, associate professor in 1924, and professor in 1929. Dr. Diehl has been a member since 1950 of the Health Resources Advisory Committee, Office of Defense Mobilization.

Health Association which set criteria for the institutions, facilities, staffing, and courses, and for the matriculation qualifications of candidates for graduate degrees in public health. These standards, as is appropriate for educational institutions in a rapidly developing field of knowledge, allow the schools wide latitude for experimentation and diversity in their approach to the three major functions which they have in common with other institutions of higher education—instruction, research, and community service.

Instruction

All schools of public health have common goals in their programs of instruction. The first of these goals is to give all students a broad understanding of the principles on which public health practice is based. The second is to train specialists in the various fields of community health services.

As a result of differences in emphasis, departmental organization and course requirements in schools of public health are less highly standardized than in institutions of some other health professions such as medicine and dentistry. All schools of public health require candidates for the degree of master of public health to take at least 2 subjects (biostatistics and epidemiology) in what may be termed the basic public health sciences and at least 2 subjects (public health administration and environmental sanitation) in applied fields of public health. Schools differ, however, in the extent to which they require or offer special training in such subjects as microbiology, nutrition, physiological hygiene, and tropical public health among the basic sciences and in such applied fields as medical economics, maternal and child health, mental health, and industrial hygiene. Thus, some schools train specialists in 1 or more of these applied fields: public health nursing, public health education, public health engineering, or hospital administration. Some schools maintain a full range of separate departments representing the various applied fields of special training; others have fewer departments which may or may not include organized subdivisions for special fields of instruction.

Research

In terms of both faculty time and expenditures, research is a prominent activity of schools of public health. The main fields of research reported by the faculty of the schools were infectious diseases, physiology, biochemistry, and environmental sanitation. The concentration of faculty time and funds on research is higher for schools of public health than for schools of medicine or dentistry.

Community Service

The community services furnished by the faculty of the schools of public health include such activities as continuation and extension courses for people outside the university, participation in consultative services, membership on committees advisory to governmental and voluntary health organizations, and services and

Professional Education in Public Health

— A Survey of Schools of Public Health, 1950 —

By HAROLD S. DIEHL, M.D.

Report on Schools of Public Health in the United States; based on a survey of schools of public health in 1950. By Leonard S. Rosenfeld, Marjorie Gooch, and Oscar H. Levine. Public Health Service Publication No. 276. U. S. Government Printing Office, Washington, D. C., 1953. 110 pages. Price 35 cents.

• • •

SCHOOLS of public health in the United States have been organized in response to demands for personnel trained to perform the various health services which have been developed during the past century. The rapid expansion in both volume and scope of these services at each level of community life has increased the need for persons equipped to apply the accumulated knowledge in the biological and social sciences to the furtherance of community health. There is need for persons who can plan, organize, and administer health services; who can analyze and interpret trends in health conditions; who can identify questions that must be resolved for the improvement of public health activities; and who can conduct the research that provides a sound basis for

future developments. Accordingly, several universities have organized schools or departments of public health with varied organization and content of academic and field training. During their relatively short history, these universities have played a dynamic and essential role in public health progress.

Aware of the many complex problems that schools of public health face in their attempts to meet present demands for health personnel and to foresee the qualitative and quantitative demands of the future, the Association of Schools of Public Health asked the Public Health Service to make a study of the schools. The recently published Report on Schools of Public Health in the United States gives in detail the results of that study, describing the organization, staffing, educational programs, students, financial status, and needs of the schools of public health in 1950. This article represents a summarization of the major findings of the report.

Three Major Functions

The report presents data for the nine accredited schools of public health in operation in 1950 at the Universities of California, Michigan, Minnesota, North Carolina, and at Columbia University, Harvard University, the Johns Hopkins University, Tulane University, and Yale University. An accredited school of the University of Toronto and one established at the University of Pittsburgh in 1950 were not included in the study.

An accredited school is one that meets the standards adopted by the American Public

Dr. Diehl has been dean of medical sciences at the University of Minnesota since 1935. He received his medical degree there in 1918 and was appointed assistant professor of preventive medicine and public health in 1921, associate professor in 1924, and professor in 1929. Dr. Diehl has been a member since 1950 of the Health Resources Advisory Committee, Office of Defense Mobilization.

Africa and assist the faculty in explaining these problems to other students. The training of foreign students, in turn, is a significant contribution by the schools in advancing public health practice in the countries to which the students return and in promoting international understanding. Many of the foreign students who are enrolled as special students are transferred to the status of graduate students when they have overcome language handicaps and have proved their ability to meet the requirements for degree candidates.

The graduate students of the schools of public health enter with prior education and experience in a wide variety of health fields—medicine, dentistry, nursing, veterinary science, engineering, the natural sciences, and the like.

The tabulation below indicates, for all 9 schools combined, 7 fields of study in which 30 or more students were taking majors:

<i>Major</i>	<i>Number of graduate students</i>
Public health administration-----	115
Hospital administration-----	106
Public health education-----	86
Environmental sanitation-----	64
Tropical public health, parasitology-----	46
Microbiology-----	33
Epidemiology-----	30

In this connection, attention should be called to the differences among schools in the emphasis given to special fields of instruction. One-third of all graduate students majoring in public health administration were at Johns Hopkins; nearly half of those majoring in hospital administration were at Columbia University; more than one-third of the group specializing in public health education were at the University of North Carolina, which also accounted for more than one-third of those majoring in environmental sanitation. Johns Hopkins accounted for more than one-third of the graduate students specializing in tropical public health and more than one-half of those with microbiology majors, while all but 8 of those majoring in epidemiology were at Harvard or the University of California. The different schools of public health thus tend to complement each other in providing special instruction, for no one school attempts to provide intensive instruction in the entire range of public health

subjects. This division of responsibility represents a sound, economical, and thoroughly desirable development from the standpoint of the Nation as a whole.

High Cost of Training

Public health training is expensive as compared with most other fields of higher education. The relatively small number of students, the high faculty-student ratio needed for individualized instruction, the wide variety of subjects that must be included in the curriculum, and the volume of research and community service performed by the schools all contribute to the high cost of training members of the public health profession.

In addition to the \$1.5 million expended by the 9 schools for special research projects for which funds were contributed by Federal agencies, foundations, and industry, the schools spent nearly \$3 million for basic operations in 1949-50. Almost 70 percent of the cost of basic operations was for instruction, including departmental research (table 3). The remaining 30 percent of basic operating expense was for such items as plant operation and maintenance, libraries, and administration.

Although there are distinct limitations to the validity of expressing basic operating expense in terms of cost per student, a unit cost figure has some significance in drawing comparisons among professional fields and in providing an index of the Nation's investment in professional education. This study of 9 schools of public health in the United States reveals that the average basic operating cost per graduate student was nearly \$4,200 a year, a sum substantially higher than that for training in medical schools or dental schools. Although the cost per graduate student in schools of public health is high in comparison with other fields of instruction, the aggregate annual expenditure for maintaining these schools is nominal when their significance in the national and international progress of public health programs is considered, and in relation to the total expenditures for organized health services.

For the schools of public health as a group, income from tuition and fees constituted only about 14 percent of basic operating expense.

Table 3. Basic operating expense of 9 schools of public health, 1949-50

Expense item	Total		Public control ¹		Private control ²	
	Amount	Percent	Amount	Percent	Amount	Percent
Total.....	\$2, 955, 997	100	\$1, 374, 406	100	\$1, 581, 591	100

¹ 4 State universities.² 5 private universities.

Income from endowment represented 20 percent; gifts and grants supplied 25 percent; and the remainder came from State appropriations and transfers of funds from the parent universities.

In line with general patterns of financing higher education, institutions under public control differ greatly from those under private control in source of funds. The group of schools of public health affiliated with universities under private control receive 36 percent of their income for basic operations from endowments while the schools affiliated with State universities received only 1 percent of their operating income from that source (table 4). On the other hand, State appropriations and funds transferred from the parent university provided 71 percent of the income for basic operations for the schools in State universities as compared with 11 percent derived from that source in the schools whose universities were under private control. These findings have sig-

nificant implications in any analysis of the present financial status and long-range stability and flexibility of resources in the 2 groups of schools.

The basic operating expenses and income as defined in this study exclude the \$1.5 million separately budgeted for research projects. Federal research grants and contracts, as would be expected, represented the major source (56 percent) of these special funds in schools of public health in 1949-50. Results of this research as well as of research similarly supported by Federal grants in other schools and universities add greatly to our knowledge and understanding of factors that influence health. They find relatively prompt application in public health practice as one community after another develops or expands its health services in the light of clearer knowledge of health hazards and means of controlling them. The special research projects and the departmental research that is financed as part of the basic operations of the schools of public health not only afford

students contact with the methods and objectives of scientific observation and analysis but also enhance their skills in applying the research findings in the work they do when they leave the school.

Needs of the Schools

The serious postwar financial difficulties of institutions of higher learning have been widely recognized. Increasing costs, expanding responsibilities, improving standards, and decline in the share of income available from endowment and private philanthropy are among the factors contributing to these difficulties. The study of schools of public health collected information that provides a quantitative estimate of the unmet needs of these schools.

According to the judgment of the deans and others responsible for the administration of these 9 schools of public health, the schools must have additional full-time faculty and expanded or renovated physical plant and equip-

ment to meet standards of adequacy and to expand their efforts in new fields of desirable public health training. A substantial increase in faculty was considered essential in nearly all schools, representing need for an increase of 25 percent over the available number of full-time faculty in departments of basic public health sciences and of 86 percent in those representing applied fields (table 5). In most schools, the physical plants were considered inadequate, with overcrowded classrooms and laboratories. For all 9 schools combined, it was estimated that nearly \$2 million of additional annual income for basic operations was needed, while the aggregate need for construction and equipment was \$11.5 million.

Conclusions

The study summarized here and the companion Public Health Service studies of medical schools (1) and schools of dentistry (2) are significant contributions to knowledge of the financial and related problems of education for the health professions. This report, moreover, goes farther than the other two, in that it relates the development of schools of public health to trends in community health services and describes the adjustments being made by the schools to gear public health training to new health problems or to those that assume increasing proportions with advances in control of acute communicable diseases. Thus, in accord with the changing spectrum of health hazards, the schools of public health are attempting to expand their instruction and research in the field of chronic illness, mental health, and geriatrics. In response to broadening concepts of the interrelationships of physical and mental health with economic conditions and socioenvironmental factors, an effort is being made to strengthen the resources of the schools in such areas as sociology and economics. In keeping with the widening responsibilities of public and private health agencies, the schools are broadening the content of their educational programs in public health administration, medical care administration, and world health problems.

If they are to continue to set the pace for progress in public health knowledge and prac-

tice, the schools must be able to develop and adjust their programs and resources to changing health concepts, needs, practices, and organization. Dr. Lowell J. Reed, now president of the Johns Hopkins University, writes in his preface to the report:

"Professional education in public health, a relative newcomer in the broad field of education in the health professions, has been characterized by independent thought, active experimentation, and a wide diversity of approach. This experimentation provides a rich fund of experience on which to draw in evaluating the effectiveness of education in public health and in projecting future trends of development. It must continue if education in this field is to retain its place as a vital part of the structure of health services."

A broad public understanding of the origin,

development, purposes and significance of the schools of public health in the structure of the Nation's health services, such as can be gained from this report, should greatly assist the schools in meeting the ever-increasing demands being placed on them.

Assistant Secretary Appointed

Russell Raymond Larmon, specialist in economics and business administration, has been named Assistant Secretary of Health, Education, and Welfare. His appointment was confirmed by the United States Senate July 21, 1953.

A graduate of Dartmouth College, Mr. Larmon served 4 years as executive assistant to the president of Dartmouth, and since 1934 has been a professor at the college in the field of administration.

He has served as a consultant to several business organizations on top management policy and has held board membership in a number of organizations. Mr. Larmon has also served on New Hampshire State commissions and was consultant to the governor on the organization of a State store system, the Department of Welfare, and other matters of State administration. From 1942-44, he was the director of the New Hampshire State Office of Price Administration.

A veteran, Mr. Larmon served with the United States Navy from 1917-18. He is a resident of Hanover, N. H.

The U. S. Public Health Service Clinical Center

for laboratory and clinical research
in medicine and public health

Symbolic as the shape in which it is built—that of the cross of Lorraine—is the role destined for the new Clinical Center of the National Institutes of Health, the research arm of the Public Health Service in the Department of Health, Education, and Welfare. Here those who travel the paths of laboratory and animal research and clinical investigation will meet and intermingle. Clinical evaluation will flow directly and naturally from basic findings. Laboratory assessment will be immediately available for phenomena observed at the bedside. Knowledge and techniques peculiar to dozens of clinical and scientific specialties can be harnessed to a single problem. These are not new concepts nor new attempts, but they are significant in scope and intensity. There is nothing random in the aim of this research institution. The Center exists to increase the pressures on the points which suggest potentially greatest returns toward the goal of making human lives longer and more productive.

These pages provide some descriptive details of this new research resource, supplementing material published in August 1952 (pp. 819–

823) and with the frontispiece of the August 1953 issue. Following the general “question and answer” and illustrative material will be found the full dedicatory address of the Secretary of Health, Education, and Welfare and excerpts from remarks of the Surgeon General and the director of the National Institutes of Health.

The Clinical Center of the Public Health Service, Department of Health, Education, and Welfare, is an integral unit of the National Institutes of Health, located in Bethesda, Md., approximately 8 miles from the center of Washington, D. C.

The Clinical Center’s construction was authorized in the Public Health Service appropriations act for fiscal year 1948, and its doors opened for admission of study patients July 1, 1953.

Background

Q. How did the concept of a Clinical Center within the Public Health Service arise?

A. The proposal for a “research hospital” where results obtained from laboratory investi-

tice, the schools must be able to develop and adjust their programs and resources to changing health concepts, needs, practices, and organization. Dr. Lowell J. Reed, now president of the Johns Hopkins University, writes in his preface to the report:

"Professional education in public health, a relative newcomer in the broad field of education in the health professions, has been characterized by independent thought, active experimentation, and a wide diversity of approach. This experimentation provides a rich fund of experience on which to draw in evaluating the effectiveness of education in public health and in projecting future trends of development. It must continue if education in this field is to retain its place as a vital part of the structure of health services."

A broad public understanding of the origin,

development, purposes and significance of the schools of public health in the structure of the Nation's health services, such as can be gained from this report, should greatly assist the schools in meeting the ever-increasing demands being placed on them.

Assistant Secretary Appointed

Russell Raymond Larmon, specialist in economics and business administration, has been named Assistant Secretary of Health, Education, and Welfare. His appointment was confirmed by the United States Senate July 21, 1953.

A graduate of Dartmouth College, Mr. Larmon served 4 years as executive assistant to the president of Dartmouth, and since 1934 has been a professor at the college in the field of administration.

He has served as a consultant to several business organizations on top management policy and has held board membership in a number of organizations. Mr. Larmon has also served on New Hampshire State commissions and was consultant to the governor on the organization of a State store system, the Department of Welfare, and other matters of State administration. From 1942-44, he was the director of the New Hampshire State Office of Price Administration.

A veteran, Mr. Larmon served with the United States Navy from 1917-18. He is a resident of Hanover, N. H.

Investigations of high blood pressure. A large number of patients will be studied over a long period to observe the natural history of the condition and to find better therapeutic agents or procedures. The hypertensive patients selected for study will probably remain in the Clinical Center for about 1 month for thorough initial study and then return for 2 or 3 days at monthly intervals for followup observation or treatment. Because of the complexity of the medical problem, a great number of laboratory and special research studies will be required in the evaluation of patients. Blood chemistry studies of the most exhaustive types will be carried out, as will metabolic studies with particular reference to diet and drugs.—*National Heart Institute.*

Studies of the periodontal diseases. These investigations will involve such problems as reattachment of tooth-supporting structures which have become detached or loosened by diseases of the soft tissues of the mouth.—*National Institute of Dental Research.*

Q. What is the relationship between laboratory scientists and clinical investigators in the conduct of research?

A. One of the major goals of the Clinical Center is to bring together in close intellectual and physical proximity virtually all of the clinical and laboratory disciplines. Scientists representing many specialties will be afforded opportunity to exchange ideas and information not only in the course of their studies, but also through casual and informal contacts.

Q. What is the relationship among the various Institutes conducting studies in the Clinical Center?

A. The collaborative nature of much research at the National Institutes of Health will be a significant factor in the overall research program relating to the Clinical Center. Many studies must cut across Institute lines. Hypertension, for example, is not a problem confined to the Heart Institute. It is thought to extend directly into the areas of metabolic and emotional disturbances, and so the study of this entity may involve at least three Institutes. In the Clinical Center, study patients of the seven

Institutes will receive patient care services from the Clinical Center central staff. Thus, the patient care facilities of the Clinical Center become a service to be shared in common by the several research programs.

Q. What is the relationship of outside investigators to the Clinical Center?

A. The Public Health Service will provide opportunities for a limited number of established scientists from other research institutions to work in the Clinical Center, usually for a year or less, on problems of their own choosing. They will be furnished space, equipment, technical help, and professional collaboration. Training opportunities will also be made available to young laboratory scientists and to physicians who have finished general internship and 2 years of residency training, thus enabling them to obtain specialized preparation for careers as independent investigators.

Q. What radiation facilities does the Clinical Center provide?

A. To study the diagnostic and therapeutic application of ionizing radiations, the Clinical Center will devote one entire wing, three stories underground and five above, to radiation therapy and research. Special safety features have been incorporated into the design of this wing—shielding, special ventilating and plumbing, and special laboratory equipment and floor surfaces. A unique feature of the radiation wing is the provision of rooms for patients, making possible supervised control of radioisotopes for diagnosis and treatment. Special laboratories in the radiation wing will be used to prepare medications containing radioisotopes, and for their subsequent extraction, purification, and chemical analysis from excretions and tissues.

Q. What can we expect from the Clinical Center research program?

A. The Clinical Center represents an important addition to the Nation's medical resources. It must be remembered, however, that advances in medical science are gradual and represent the cumulative efforts of thousands of scientists and physicians throughout the world. The Clinical Center is a highly developed laboratory.

Its specialized and diversified staff should help bridge the gap between laboratory and clinical research, and between the various special branches of medical science.

Q. Does the Clinical Center train interns and student nurses?

A. No. However, "clinical fellows" who are the equivalent of second- or third-year residents in the ordinary hospital, may qualify for several of the specialties through service in the Clinical Center. Similarly, graduate nurses will receive special training in the care of patients in broad disease categories and in clinical research nursing.

The Research Patient

Q. What are the standards of admission for patients under study at the Clinical Center?

A. Because research is the main function of the National Institutes of Health, the patients admitted to the Clinical Center by a given Institute must meet the terms of investigation as set by that Institute. He must, therefore, *be chosen for admission* as a subject who has those characteristics of a disease or disorder about which National Institutes of Health scientists are asking questions and hope to find the answers. On occasion, a limited number of "healthy" persons will be admitted in order to establish the normal against which the pathological can be measured. No study patient will be admitted unless he is referred through professional channels.

Q. How will it be determined that patients are suitable for study purposes?

A. The Institutes will ask physicians, hospitals, and clinics to refer to them those patients who appear to meet the needs of particular studies. The diagnosis of the patient by his attending physician and further diagnostic checks at the Clinical Center itself will be of paramount importance in determining suitability of patients for Clinical Center admission.

Q. Will patients with rare diseases or diseases which have not been diagnosed qualify for admission?

A. As a general rule—no.

Q. Where will patients be drawn from?

A. It is believed that most patients will be obtained from the eastern seaboard States (a) as a matter of convenience to patients, their families, and their doctors, (b) in order to facilitate medical followup, and (c) in order to reduce the cost of transportation. Under certain circumstances, especially when the condition to be studied is not prevalent in this area, it will be necessary to admit patients from more distant places.

Q. How long will patients remain in the Clinical Center?

A. This will depend on the nature of the study and the condition of the patient. Some studies may require that patients remain under observation for 6 months to a year. Studies of the acute infectious diseases, however, may require a stay of only a few days to a few weeks.

Certain investigations will require that patients remain at the Clinical Center for several weeks of study, then report periodically to the Center on a followup basis for long periods of time. In a limited number of studies, patients will not be admitted to the Clinical Center as bed patients but will report on a regular basis to the research teams for observation and tests.

Q. Are there any special facilities for care of the long-term patient?

A. The Clinical Center has been built with the understanding that hospitalization for prolonged study demands special facilities. Each room will normally have two patients, except when the condition of the patient requires a private room (as in the case of certain psychiatric studies or patients with infectious diseases). The entire building is air-conditioned, and each patient room has a complete bathroom. On each floor is a solarium with comfortable lounges and chairs for patients and their visitors. Indoor and outdoor recreational facilities have been provided, and a library will be available for patients. It is expected that concerts and movies will be presented in the patients' assembly room on the top floor. Protestant, Hebrew, and Catholic services are

to be conducted regularly in the Center's chapel.

Q. Who will be the patient's physician while he is in the Clinical Center?

A. Each patient will have as his physician a qualified clinician from the Public Health Service staff. He will perform the full range of services and assume the responsibilities of the personal physician for the duration of the patient's stay in the Clinical Center.

Q. What is the relationship of the patient's own physician to the patient while in the Clinical Center and afterward?

A. The patient's own physician will be welcomed in the Clinical Center to visit the patient and confer with the staff. Full reports on each patient will be made at suitable intervals

to the referring physician or institution. On discharge, the patient is referred back to his physician or institution, or both, and the results of treatment and recommendations for further therapy, if desired, will also be made available. In cases requiring followup observation and therapy, appropriate arrangements will be made with the patient's physician.

Q. Does the Clinical Center have medical facilities available for routine treatment of persons in the local area?

A. No. The Clinical Center operates solely as a research facility. The only exception—as is true of all hospitals and clinics—will be the treatment of emergency cases, such as victims of nearby automobile accidents. Such patients will be transferred to the regular general hospitals of the area as soon as it is safe to do so.

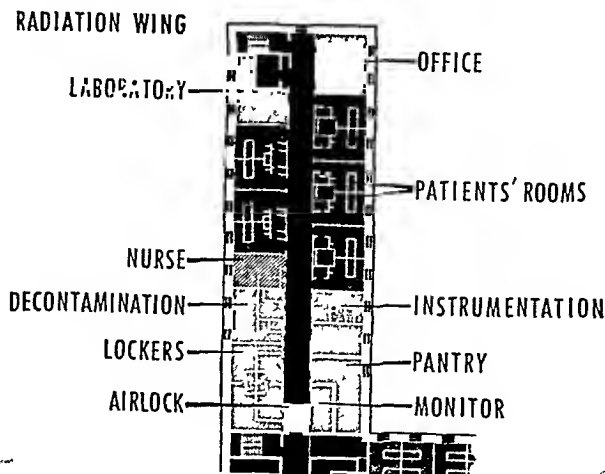

The Clinical Center Structure

The Clinical Center is designed in the shape of a Lorraine cross in which the central stem of 14 floors is divided lengthwise by 2 corridors. Rooms for patients are located on the south side, separated by a corridor from nursing and related patient services. Clinical research laboratories are along the north corridor. Fundamental research will be conducted in the 6 wings, each of 11 floors. One of these wings (see drawing) is designed especially for radiation studies.

[For schematic floor plans showing the interrelationships between facilities for patients and the clinical and basic laboratory space, see *Public Health Reports*, August 1952, p. 821.]

Patients are cared for in 2 nursing units on each floor, with 13 rooms and a capacity of 26 patients. Typical rooms (see picture 1) are 17 feet long by 11½ feet wide. The nursing station (picture 2) is centrally located in each unit and equipped for economical and efficient service, including voice communication with each patient.

With the welfare of the study patient as a primary consideration, facilities have been provided to make their stay in the Clinical Center as comfortable to them as practicable. A chapel (picture 3) provides regular Protestant, Hebrew, and Catholic services, and clergymen of each faith have offices in the Center. Recrea-

tional facilities are available. Each floor has a solarium for patients which is reached by connecting corridors separate from the laboratory and general public spaces in the building. A

sun deck (picture 4) looks over the rolling hills of Bethesda. Other buildings on the grounds of the National Institutes of Health may be seen, with the National Naval Medical Center in the background.

In addition to 500 beds for study patients, the Clinical Center contains some 1,100 12-by 20-foot modules in the laboratory areas. Flexibility in research space is provided by demountable partitions (picture 5). Laboratory utilities—illuminating gas, vacuum, distilled and hot and cold water—come up the main walls every 12 feet. Plumbing in the partitions brings utilities to the benches and sinks. One of the clinical laboratories, ranged along the north side of the main stem, is shown in picture 6. This is a 2-module unit. Picture 7 shows a 1-module unit in one of the laboratory wings provided for basic investigations.

Several ancillary buildings (picture 8) service the Clinical Center and other units of the National Institutes of Health. Heating, air-conditioning, and a plant for emergency power production are provided in one building. Adjacent are shops, storage, and laundry buildings; incinerator; animal buildings; a grounds maintenance building; and a general utility building. A tunnel permits materials to be transported directly from shops and storage bins to research space in the Clinical Center without the necessity of reloading carts and

trucks. Auxiliary functions are placed in service structures outside the Clinical Center to reduce construction costs and to avoid uneconomical use of research space, as well as to reduce such factors as smoke, traffic, and maintenance activities in the Center itself. An apartment building (containing, for the most part, efficiency apartments, but with a small number of 1- and 2-bedroom units) is still under construction immediately adjacent to the Clinical Center. It will provide housing for medical, nursing, engineering, and maintenance staff whose duties require them to be available for emergency calls.

The Clinical Center building program (which includes, in addition to the Center itself, the various auxiliary structures, land, roadways, storm sewers, and so forth) on completion, fully equipped, will represent a total investment of approximately \$64 million. Rough breakdown is as follows: \$3.5 million—site acquisition and original plans; \$34 million—the Clinical Center building itself; \$8 million—laboratory equipment and initial supplies; \$17.5 million—fully equipped auxiliary structures (boiler plant, shops, laundry, warehouse, animal facilities, chemical storage, grounds maintenance, isotope laboratory, and general utility building); \$1 million—apartments for resident

staff performing emergency patient-care duties.

The Clinical Center itself contains 1,266,400 square feet gross, of which 55 percent is net space.

"A Symbol of Our National Concern For the Health of Our People"

Address of Oveta Culp Hobby, Secretary of Health, Education, and Welfare, in dedication of the Public Health Service Clinical Center July 2, 1953, at Bethesda, Md.

It is impossible to stand here today without a feeling of tremendous excitement—the excitement one always feels in the face of an infinite potentiality.

In his book entitled "Death Be Not Proud," John Gunther wrote courageously and beautifully of the gradual death of his son Johnny from a brain tumor. One passage I shall always remember was this: "People may ask if it would not have been better if we had had fewer doctors and less treatment. Perhaps we tried to do too much. But Johnny loved life desperately and we loved him desperately and it was our duty to do absolutely everything and keep him alive as long as possible. Always we thought that, if only we could maintain life somehow, some extraordinary *new* cure might be discovered."

No human being who has ever loved another human being can fail to understand the urgency that hour by hour, minute by minute, the Gunthers felt as they fought off death for their brilliant, endearing son.

The cure did not come in time for Johnny Gunther nor for tens of thousands of others who have the so-called incurable diseases.

New Solutions Ahead

But with the opening of this Center today, we can envision cures as yet unthought of which will bring life to the desperately ill, which in their hour of need will ease the desperation of parents whose children are as yet unborn.

Each new solution to be found here will mean a new chance at the full and finished life for numberless men, women, and children—each

one a human being who loves life, each one loved by someone else.

The opening of this Center today in no way minimizes the work of the solitary research scientist working alone. It will aid him and the forces of research scattered across the country.

This Center will provide a focal point for all who inquire—for all who seek sources of life and the causes of death.

This is a practical step, taken by our Government as trustee for the people, toward the threefold goal of improving the health, education, and welfare of our citizens. It will better public health by hastening the conquest of disease; it will widen the bases and the horizons of medical education, and in both these ways it will contribute to the general welfare of the Nation.

A Collaborative Effort

The purpose of the Center—to facilitate and improve medical research—is part of a research program which has gained spectacular impetus since World War II. We are now carrying on in the United States the most intensive and widespread research attack on human disease which the world has ever seen. It is a collaborative effort—a close partnership between the Federal Government and the medical, research, and related professions, universities and medical schools, and numerous nationwide organizations of citizens. Every year the effort widens, as new and old organizations concentrate on specific killers of mankind.

The part played by the Federal Government in this intensive research program is an important one. In fact, half of all research in

medical schools is now financed by the Federal Government. This Department now supports seven research institutes, all of them located at Bethesda. In 1953 Public Health Service grants and related training activities totaled \$22.5 million. This investment has contributed dividends to the kind of medical knowledge which, since 1900, has helped to lengthen our national life span by about 20 years and has taught us how to control or eliminate diseases which once were national scourges.

For example, it was a Public Health Service doctor who discovered that pellagra was a dietary deficiency disease, thus leading to its final conquest. Here, in these Federal research institutes, Rocky Mountain spotted fever was identified and a vaccine against it discovered. Here were made early discoveries about Q fever, and here a vaccine against typhus fever was found, a knowledge which has saved the lives of countless numbers of our troops.

Milestone of Progress

The Clinical Center which we are dedicating today is a milestone—a very big milestone, as you can see—on this road of progress. By this joining, under one roof, of hospital, clinic, and research laboratories, the research scientists are acquiring a new and powerful tool in their endless struggle to unlock the stubborn secrets of disease and build a better life for all of us.

The need for uniting clinical studies more closely with laboratory research was first voiced by the Surgeon General of the Public Health Service as long ago as 1911: "The time has now come when in order to obtain the best results from laboratory work there should be available a hospital attached to the laboratories to which patients suffering from a particular disease which it is desired to study could be admitted, so that the cases could be studied throughout all the stages of the disease." He had the vision, but it has taken 42 years for that vision to materialize into this reality.

Initial funds for building this Clinical Center were finally authorized and the first money appropriated in 1947 by the 80th Congress, and you see the result here today. It is not only a symbol of man's untiring search for knowledge and a better life. It is a monument of

what can be accomplished when there is unity of purpose and free cooperation toward a worthwhile goal.

For the Clinical Center is in no sense a partisan, politically inspired enterprise. Though funds for its construction were voted by a Republican Congress, the vote was on a nonpartisan basis, with both Republicans and Democrats supporting it.

The late beloved Congressman Frank B. Keefe of Wisconsin was its principal champion in the House, and his success in winning nonpartisan support was shown when the measure passed without a single dissenting vote.

In the Senate, Senators Styles Bridges of New Hampshire and William Knowland of California were among its skillful and successful backers. There, too, it won support from both major parties.

The reason for this nonpartisan approach toward the Clinical Center and toward similar measures to improve the Nation's health is not hard to find. For the Center is an instrument in the unceasing search of science for truth, and scientific truth knows no politics—at least in a free society.

A Unique Structure

As you can see, the building itself is a unique structure. Built in the shape of a Lorraine cross, it is really a set of laboratories wrapped around a 500-bed hospital. No more dramatic revelation of the complexity of modern medicine could be devised than the fact that a structure as large and complicated as this is necessary to bring together all the trained doctors and scientists needed for a full-scale attack on the diseases which are being studied here.

The building has been designed to have the utility and flexibility necessary to meet the ever-changing requirements of laboratory research, patient care, and sound administrative practices.

Patients who come here will have medical care as good as any in the world. The most advanced research techniques will probe into the causes and attempt to find ways of curing and preventing the diseases from which they suffer.

This will be far more than simply another

Federal hospital. All its patients will be referred by medical sources and chosen on the basis of their relation to the disease problems currently under study at the Center. They may remain in the hospital for long periods of time, and after they are discharged, they will be observed closely for periods ranging from a few months to 10 years or more. Their welfare will at all times be the first consideration.

A National Institution

The Clinical Center will be a truly national institution—an invaluable asset which will enrich the resources of our universities and medical schools and a laboratory where scientists from other countries can pursue their studies, thus widening not only their own knowledge but ours. But this Clinical Center's meaning, it seems to me, goes deeper than that. It is a logical outcome of the original concept of this country held by the men who founded it.

These men used powerful phrases to express their concept—phrases which are as strong and vigorous today as when first written a century and three-quarters ago.

From the Declaration of Independence, "We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty and the pursuit of Happiness."

Will not this Center strengthen human hold on life and make easier the pursuit of happiness?

And from the Constitution, "We, the people of the United States, in order to form a more perfect Union, establish justice, insure domestic tranquility, provide for the common defense, promote the general welfare, and secure the blessings of liberty to ourselves and our posterity . . ."

What single institution could be expected to do more for the general welfare or to secure the blessings of liberty to ourselves and our posterity?

This Center is the way responsible government—as trustee for the people—fulfills the obligation placed upon it by the Constitution.

It is new evidence that the United States Government continues to be responsive to the people and to the needs of the people.

I proudly dedicate this Center to medical research as a symbol of our national concern for the health of our people, for their right to pursue happiness unhampered by crippling pain and illness.

In freedom, this building and the people who work here are dedicated to the endless struggle against human suffering.

We are dedicating it today—dedicating it to the open mind of research—dedicating it as an example of democracy heeding its obligation to free men, who, together, are self-governing.

Additional Details

. . . concerning Clinical Center operations and policies will be found in three new publications of the Public Health Service.

*"We must press the search for new knowledge
... use what we know more effectively"*

Extracts from remarks of the Surgeon General of the Public Health Service at the dedication of the Clinical Center.

The opening of the Clinical Center symbolizes the hope and faith of the American people that the major killing and crippling diseases of this century ultimately will be conquered.

The very nature of these diseases—subtle reactions of the human organism to its biological inheritance, its total environment—makes it clear that clinical and laboratory research will play an increasingly significant role in medical and public health progress for many years to come.

In a sense, we have reached a period of consolidation of forces for a broad attack on chronic diseases—an attack that can be fully successful only after years of intensive research. This means that we must not only press the search for new knowledge, but we must also use what we do know more intensively, more effectively.

The key to chronic disease control today is early diagnosis and treatment. Hundreds of thousands of the people who will die of cancer or heart disease, or who will be permanently disabled by arthritis or neurological disorders, or mental disease, could be aided if their illnesses were detected in the early stages when present methods of treatment are most successful. The first great promise of medical research is to find new and more efficient ways to early diagnosis and treatment. And the second is ultimately to discover means of positive prevention.

In centering attention on the chronic diseases, we will not forget that our knowledge of infectious diseases—particularly the virus infections—is really quite rudimentary, when measured against what must be known if prevention is to be as successful in the whole range of communicable diseases as it now is in a few. We must not forget the interrelation of many acute

infections and chronic disability: the crippling effects of poliomyelitis and encephalitis, for example.

If the Nation's total effort in medical and public health research maintains effective balance and emphasis with respect to all our major problems, the American people can expect advances in human health in the second half of this century as startling as those that have marked the first half.

The Clinical Center will take its place with other major research institutions, private and public, in this long, hard fight.

The Clinical Center, however, is not only a research institution; it is a piece—a large one, it is true—in the kaleidoscope of public health. It is a part of the Public Health Service, and thus a part of the United States Department of Health, Education, and Welfare.

We in the Public Health Service, and our colleagues both inside and outside the Federal Government, have long since recognized the inseparability of science and the society in which it functions. We cannot separate a rheumatic child's illness from his growing mind and body, from his immediate need for schooling, his family's potential need for social service. Nor can we separate the cancer patient's disease from his age, his potential unemployability, or his pension. We cannot separate the crippled workman's paralysis from his chances for rehabilitation and return to gainful employment and happy independence.

The opening of the Clinical Center follows by less than 2 months the establishment of the Department of Health, Education, and Welfare—acts which demonstrate America's nationwide recognition of these relationships. . . .

—LEONARD A. SCHEELE, M. D.

"An atmosphere of excitement, of high expectation and a knowledge . . . of serving mankind"

Extracts from remarks of the director, National Institutes of Health, at the dedication of the Clinical Center.

The United States now has a medical research establishment as fine as any in the world. This building, in its unique and original design, supplies the facilities that are essential for the close interworking of clinical and laboratory research scientists which is required by the intricacies of the search for the cause and treatment of diseases such as heart disease, mental illness, cancer and the other killing, crippling, and chronic diseases with which we will be working. The Clinical Center will make possible research of a very high caliber: our real job now begins.

Medical research is an intellectual pursuit. Its success depends entirely on the capability of the individual. If we are to succeed in this great undertaking, we must continue to attract staff of the highest professional qualifications and continue to maintain an environment in which scientific excellence is the major value. We want to create in this building the atmosphere of excitement, of high expectation and a knowledge of the happiness that can be achieved in serving mankind—the things that are common to all great research institutions.

We want our patients to feel they are our colleagues in research and to experience this same atmosphere. They will receive the best care that medical science can provide. Our

moral obligation to do our best to treat the sick is paramount. Clinical studies will go forward within limits set by the welfare of patients. Not only is this a moral imperative—but it is the only way that sound clinical research can be done. These objectives and principles will guide the National Institutes of Health.

In extending our research organization we face the complex problem of establishing the proper relative emphasis upon laboratory and clinical research. We will fail if clinical research overshadows or replaces laboratory work, and we must insure that clinical observations are fully developed in the laboratory.

To those who are not acquainted at first hand with the operation of a research organization these problems may seem abstract. To those who are familiar with the problem I need say no more.

As we today dedicate this building we are merely saying—this is the beginning. We deeply appreciate the faith that the Congress has shown in our assurances that this great investment in medical research will pay off in benefit to the health and welfare of the people of the United States. It will be our job now to make good those assurances. . . .

—WILLIAM H. SEBRELL, JR., M.D.

Health Department Manpower

In the spring of 1951, the Public Health Service collected information concerning personnel employed and vacancies in positions for professional and technical public health workers in State and local health departments of the continental United States and the Territories. This was done at the request of the Health Resources Advisory Committee of the Office of Defense Mobilization, a committee appointed to consider the availability and use of health resources, including personnel, during the period of defense mobilization. The information obtained was reported to the committee at two of its meetings in the winter of 1951-52, and was the subject of an article by Dr. William P. Shepard, a member of the committee, published in the *Public Health Reports* for August 1952. Final analysis of all data collected and source material for reference purposes have been included in Public Health Monograph No. 13, entitled "Staffing of State and Local Health Departments, 1951."

No later comparable data are available to provide a basis for determining whether the staffing problems of State and local health departments have eased in the past 2 years. From reports on personnel submitted periodically to the Public Health Service by State health departments, the assumption that the personnel situation is still critical appears to be justified. Recruitment of qualified public health workers still lags far behind needs. Established positions that were vacant in the spring of 1951 are, in many instances, still vacant. The "doubling up" of assignments, the discontinuance of programs and services, and the search for candidates for employment continue.

Vacancies in budgeted positions reported by State and local health departments represent only immediate and urgent needs for particular categories of public health personnel. They by no means indicate the extent of total need, even for minimum staffing requirements. To

Public Health

MONOGRAPH

No. 13

The accompanying summary discusses the principal findings presented in Public Health Monograph No. 13, published concurrently with this issue of Public Health Reports. The authors are with the Bureau of State Services, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

Haldeman, Jack C., Cheney, Bess A., and Flook, Evelyn: Staffing of State and local health departments, 1951. Public Health Monograph No. 13 (Public Health Service Publication No. 279). U. S. Government Printing Office, Washington, 1953. Price 30 cents.

bring existing health department staffs up to the recommended minimum standards would require the services of many more public health workers than the number needed to fill reported vacancies.

Among the personnel employed at the time of the survey, many held status in the various components of the military reserve; many physicians, dentists, and veterinarians had been registered and assigned priorities under

the "Doctor Draft Law"; and many more were in the older groups, approaching an age when, even though still actively at work, the services they are able to render must be expected to decline both in quantity and quality. In a national emergency, in which large numbers of trained public health workers would be needed urgently and on short notice, it seems evident that State and local health departments would of necessity be stripped of many of their able-bodied staff members.

For budgeted positions and vacancies, information is available from 1,257 local and 44

State health departments in the United States. For personnel employed in 1951, reports cover 1,470 local and all 48 State health departments. Information is provided for the continental United States as a whole and divided among four broad geographic regions, according to type of department—county, city, local health district, State health district, or other—and according to the population served—in communities of under 35,000 to those of half a million or more. Generally comparable data from the Territories—Alaska, Hawaii, Puerto Rico, and the Virgin Islands—are also included.

To the Professional Public Health Worker

You, like the specialist in medical and other fields of science, know how important it is to be informed on current knowledge in your specialty. And, for the most part, you rely on the first-hand availability of the leading journals and periodicals in your specialty.

But as more becomes known of public health practice and research, the more complex this science becomes. There comes too the need to relate the activities of all its component disciplines—the members of the family of public health—one to the other, and each to the whole. And for each specialist there is a need to read regularly the journals devoted to unifying the family of public health. *Public Health Reports* is such a journal.

Trends in Tuberculosis Mortality

In Continental United States

By ALBERT P. ISKRANT, M.A., and EUGENE ROGOT, B.S.

THE NUMBER of deaths and the death rate from tuberculosis continue to decrease very rapidly in the United States. In 1950, there were 33,959 tuberculosis deaths, a decline of 13 percent from the number in 1949. The death rate per 100,000 population for 1950 was 22.5, a decline of 14 percent from the rate for 1949. Further declines were realized in 1951 and in 1952. Estimated figures for 1951 show declines from 1950 of about 13 and 15 percent,

respectively, in the number of tuberculosis deaths and in the death rate; similar declines are noted for 1952 in comparison with 1951.

The yearly changes in the number of deaths and in the death rate in the United States for 1933 through 1952 are shown in table 1. (In this table and throughout the report, numbers of deaths for 1940-52 exclude deaths among Armed Forces personnel overseas, and rates are based on population excluding the Armed Forces overseas.) The striking downward trend in the tuberculosis mortality rate was interrupted only once in this period, in 1936. In recent years the rate of decline has accelerated. Since 1945, the tuberculosis mortality rate has been reduced by 60 percent. It is interesting

Mr. Iskrant is chief of program analysis in the Division of Chronic Disease and Tuberculosis, Public Health Service. Mr. Rogot is an analytical statistician with the division.

¹ Total includes age not stated.

² Rates based on Apr. 1, 1950, enumerated population.

NOTE: The Death Registration States increased from 10 States and the District of Columbia in 1900 to the entire continental United States in 1933.

to note that the period of accelerated decline coincides with the period which witnessed the growth of combined Federal-State antituberculosis programs, intensified X-ray screening activities, and increased emphasis on tuberculosis control generally.

Trend by Age

In 1900, 3 out of every 4 tuberculosis deaths were among persons under 45 years of age. The mortality rate for this age group was 185.0 per 100,000 population, compared to a rate of 228.6

Table 3. Death rates for tuberculosis (all forms), by age, in continental United States, 1900 and 1950

Age (years)	Rate per 100,000 population			Age (years)	Rate per 100,000 population		
	1900 ¹	1950 ²	Percentage decline		1900 ¹	1950 ²	Percentage decline
All ages.....	194.4	22.5	88.4	25-34.....	294.3	19.1	93.5

1-4.....	101.8	6.3	93.8	45-54.....	215.6	35.9	83.3
5-14.....	36.2	1.8	95.0	55-64.....	223.0	47.7	78.6
15-24.....	205.7	11.3	94.5	65-74.....	256.1	57.7	77.5
				75 and over.....	269.2	60.9	77.4

¹ Rates for the Death Registration States; 10 States and the District of Columbia.

² Rates based on Apr. 1, 1950, enumerated population.

for age 45 and over. In 1950, only 42 percent of the deaths were among persons under 45 years of age. The death rate for the "under 45" age group was 13.1, compared to a rate of 46.1 for the "45 and over" age group.

The tuberculosis death rates for these two age groups at 5-year intervals from 1900 to 1935 and for each year from 1935 through 1950 are shown in figure 1 and table 2. Both groups showed a remarkable decline in tuberculosis mortality, but with a highly significant difference. The relative difference between the rates for the two groups has been growing at an ever-increasing pace. Tuberculosis mortality has declined more rapidly among younger persons than among older persons and probably will continue to do so.

A comparison of tuberculosis death rates for 10 age groups for 1900 and 1950, shown in table 3, provides evidence that the younger age groups have shown higher percentage declines than the older groups. In fact, with only one exception, each age group has shown a greater percentage decline than the next older age group.

Figure 1. Age trend in tuberculosis death rates, 1900-1950 (expanding Death Registration States).

Trend by Race and Sex

Since 1910, tuberculosis mortality has been reduced dramatically for each race-sex group (figure 2 and table 4). Declines in the death rate between 1910 and 1950 ranged from 84.2

¹ Rates based on Apr. 1, 1950, enumerated population.

NOTE: The Death Registration States increased from 20 States and the District of Columbia in 1910 to the entire continental United States in 1933.

Figure 2. Comparison of tuberculosis death rates for race-sex groups in 1910 (Death Registration States) with 1950 (continental United States).

percent for white males to 91.9 percent for white females. For each race, the rates for females dropped faster than for males. In recent years

this sex difference in the mortality decline has become increasingly pronounced.

The characteristic pattern exhibited by tuberculosis mortality for this period has been one of highest mortality in the nonwhite male group, followed in order by the nonwhite female, white male, and white female groups. This pattern has prevailed throughout the period with the exception of two intervals, 1916 and 1919-29, during which the mortality rate for nonwhite females was slightly higher than for nonwhite males.

Current Mortality

Tuberculosis deaths and death rates by age for 1949 through 1951, together with an average for these 3 years, are shown in table 5. As shown by these data, the lowest death rates occur in the younger age groups, and generally the tuberculosis mortality rates increase with age. The tuberculosis mortality level for each age group in 1951 was lower than for the corresponding age group in 1950 and in 1949.

Tuberculosis mortality by race and sex for 1949 through 1951 is presented in table 6. It may be seen here that the rate among males is about twice that among females, and that the rates for nonwhites are more than three times the rates for whites. All groups, however, had lower rates for 1950 than for 1949, and lower rates again for 1951 than for 1950.

A breakdown of tuberculosis mortality by age, race, and sex for 1950 is given in table 7. Important differences may be noted in the ages at which highest mortality occurs in each race-sex category. For white males, the death rates increase almost continuously with age, reaching a high point of about 85 per 100,000 population in the age group 65-74 years. The rate for white females, on the other hand, is fairly uniform from age 20 through age 64, and then rises to a peak at age 75 and over. After age 30, white males generally have higher mortality rates than white females; before age 30, the reverse is true.

Nonwhite males have a higher mortality rate than nonwhite females at ages beyond 30 years. At ages under 30, nonwhite females generally have the higher rates. The pattern for nonwhites is essentially the same as for whites.

The peak age of death is reached between ages 45 and 64 years for nonwhite males and between ages 20 and 34 years for nonwhite females. Both groups show minor peaks for ages under 5 years, then drop to their minimum rates, rise to their major peaks, and finally taper down at the older ages.

Table 8 shows tuberculosis deaths and death rates for 1950 by specified form of disease. The great bulk of the deaths, more than 90 percent, were due to respiratory tuberculosis. Of the 2,866 deaths from nonrespiratory tuberculosis, more than one-third were due to tuberculous meningitis and almost another third to disseminated tuberculosis.

Years of Life Lost

In studying mortality from any disease, it is often useful to obtain some measure which takes into account not only the actual number of deaths from the particular disease but also the age distribution of these deaths. Generally, the younger the age at death, the greater the loss to society. Thus, to fully appreciate the impact of mortality from a given disease, it is necessary to compute a measure which weights each death according to the age at death—the younger the age, the greater the weight assigned to it. This has been done for tuberculosis deaths for 1940 and 1950 (tables 9 and 10).

For 1940, the actual weights used were the

¹ Value given for \bar{e}_x at age 90 is used.

life expectancy values taken from a life table from which tuberculosis as a cause of death had been eliminated. The number of deaths for each age group was multiplied by the life expectancy for the particular age group. (The life expectancy was taken at the midpoint of the age interval, since it is assumed that all

deaths in a given age group occur at the midpoint.) The product is the number of years of life that the age group could expect to live if tuberculosis had been eliminated as a cause of death. The sum of the products indicates the total potential years of life lost for the entire group.

Nonwhite female.....	4, 071	8, 020	3, 949	49. 2	144	288	144	50. 0

For 1950, years of life lost were computed similarly. No life table with tuberculosis eliminated was available for 1950, however. Hence, the potential years of life lost for the 1950 tuberculosis deaths are slightly understated.

As shown in table 11, somewhat less than a million years of life were lost by tuberculosis deaths in 1950. This represents a decline of 910,000 years, or 50.4 percent, from the staggering 1,806,000 years lost as the result of the 1940 tuberculosis deaths. All race-sex groups shared in the general decline, each group showing a substantial reduction during this period.

A comparison of the percentage decline in deaths with the percentage decline in years of life lost shows that each race-sex group had a greater decline in the latter. This is a result of the increasing age at death from tuberculosis,

a fact which should be cited as one of the notable achievements in tuberculosis control.

Conclusion

It has been shown in this paper that tuberculosis mortality in the United States is now the lowest in history and that the greatest gains have been achieved in recent years. Moreover, the outlook for the future is encouraging. Tuberculosis, however, ranked seventh as a cause of death in 1950, and was the leading killer from disease for the 15-34 age group. The toll from tuberculosis mortality in terms of potential years of life lost amounted to about 900,000 years in 1950. It is evident from these figures alone that tuberculosis still remains a major killer and still retains its importance as a leading public health problem.

Consolidation of Public Health Service Regional Offices

The Public Health Service offices for Region I (Connecticut, Maine, Massachusetts, Vermont, New Hampshire, Rhode Island) have been consolidated with those for Region II (New York, New Jersey, Delaware, Pennsylvania). Headquarters are at New York City. Dr. Henry A. Holle is regional medical director.

Region IV offices (Kentucky, Michigan, Ohio) have been consolidated with those for Region V (Illinois, Indiana, Wisconsin, Minnesota). Headquarters are at Chicago. Dr. Harald M. Graning is regional director.

Dr. Richard F. Boyd, formerly at Boston, is now regional medical director for Region X, San Francisco. Also transferred to Region X was Dr. Welby W. Bigelow, who had been acting director for Region IV at Cleveland.

technical publications

Reported Incidence of Selected Notifiable Diseases: United States, Each Division and State, 1920-50.

Vital Statistics Special Reports. National Summaries, vol. 37, No. 9, June 15, 1953. 64 pages; tables. Available from the National Office of Vital Statistics, Public Health Service, Washington 25, D. C.

Because of the large number of requests for time series data on notifiable diseases for the country as a whole or for individual States, the National Office of Vital Statistics has issued this special summary report giving the reported incidence of selected notifiable diseases for the United States, each division and State, for the years 1920 through 1950.

A total of 31 diseases of national interest is included in the listing.

Since figures were available from comparatively few States prior to 1920, this date was selected arbitrarily as the starting point for the reports of most diseases. A few series are for shorter periods.

The tabulations show not only trends in incidence of disease, but also the changing patterns in classifying and reporting over the years.

The diseases included in the tabulations are: amebiasis, anthrax, bacillary dysentery, botulism, brucellosis, dengue, diphtheria, infectious hepatitis, acute infectious encephalitis, leprosy, leptospirosis, malaria, meningococcal infections, psittacosis and ornithosis, acute poliomyelitis, Q fever, measles, tetanus, rabies in man and in animals, Rocky Mountain spotted fever, scarlet fever and streptococcal sore throat, smallpox, trachoma, trichiniasis, tularemia, tuberculosis, typhoid and paratyphoid fever, endemic typhus, whooping cough, and plague.

— for the general public —

Coronary Artery Disease

Health Information Series No. 68, Public Health Service Publication No. 145. Revised 1953. 5 cents; \$2.25 per 100.

One of a series of four health information leaflets on the diseases of the heart (see *Public Health Reports*, vol. 67, No. 9, p. 928), this recently revised publication is concerned with one of the most common forms of heart disease.

The introductory paragraphs, describing the coronary artery system, are followed by answers to the questions of what is coronary artery disease; what can be done for coronary artery disease; how long can the person with coronary artery disease live; who gets coronary artery disease; and what is now being done to prevent coronary artery disease.

The frequently used terms angina pectoris, coronary thrombosis, and

collateral circulation are explained, and the various types of medicine used in the relief of this heart condition, and current research on its cause, are discussed. The reader is advised that under the supervision of a physician, the victim of coronary artery disease has a good chance for a useful life of many years.

Typhoid Fever

Health Information Series, No. 72. Public Health Service Publication No. 282. 1953. 1-fold leaflet. 5 cents; \$1.75 per 100.

Although typhoid fever causes relatively few cases of illness or death in the United States, it remains a public health problem in other parts of the world. This health information leaflet describes the disease, its symptoms, how it is transmitted, and present methods of treatment.

Several paragraphs are devoted to the typhoid carrier and the health problems peculiar to this condition. Preventive measures are stressed: vaccination to protect the individual and good public health and home health practices to protect the community. Suggestions are given for travelers, and readers are advised to consult their health officer or physician for further information.

Rheumatic Heart Disease

Health Information Series No. 67, Public Health Service Publication No. 144. 1953. 2-fold leaflet. 5 cents; \$2.25 per 100 copies.

The council on rheumatic fever and congenital heart disease of the American Heart Association released, in January, a statement on the prevention of recurrent attacks of rheumatic fever through the prolonged use of sulfonamide or penicillin. (See *Public Health Reports*, January 1953.)

Because of the importance of this prophylactic measure in the control of rheumatic fever and rheumatic heart disease, this health information leaflet has been revised accordingly. In addition to the general information on the nature of rheumatic heart disease and rheumatic fever, diagnosis and treatment, contained in the first edition, the leaflet now includes a paragraph on the advisability of giving children who have had rheumatic fever sulfonamide or penicillin daily, under doctor's directions, for at least 5 years.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Tuberculosis: A Time for Decision

By THOMAS PARRAN, M.D., Dr.P.H.

AS THE HENRY PHIPPS INSTITUTE celebrates its first half century of achievement, it is useful to undertake an appraisal of where we stand today in the battle against tuberculosis, and to attempt to draft the strategy for finishing the job. I realize the futility of hoping to contribute original ideas at this time for decision. All I presume to offer is a candid camera shot of the forest in which the tuberculosis experts have been doing excellent work among the trees.

That you may forbear as I attempt this, I quote Laennec, who wrote to his cousin: "Do not fear to repeat what has already been said. Men need these things dinned into their ears many times and from all sides. The first version makes them pick up their ears, the second registers, and the third enters" (1).

Dr. Parran, dean of the Graduate School of Public Health of the University of Pittsburgh, was Surgeon General of the Public Health Service from 1936 to 1948. In an article entitled, "No Defense For Any of Us," which appeared in the April 1938 issue of Survey Graphic, he suggested methods which could be followed in setting up a program for national control of tuberculosis, since many of the techniques used in the program for the control of venereal diseases, which already had been started, could be applied to tuberculosis control. During the early part of World War II, he supported the Public Health Service's experimental work on the use of small films in X-ray examinations. This work led to trials of the films on a demonstration basis. Soon afterward, in 1944, the national tuberculosis control program was authorized and began operation.

Early Approaches

Prior to 1900, public health measures were largely punitive. Quarantine, it was assumed, would erect safe barriers to the spread of epidemic disease. Later, specific immunization, long effective in the control of smallpox, was believed to be the method of fulfilling Pasteur's prophecy that "infectious disease would be banished from the earth."

Concurrently, the sanitary engineer played a major role in improving the human environment by the purification of public water supplies, the pasteurization of milk and other dairy products, and the draining or neutralizing of mosquito breeding grounds. He also initiated more sanitary methods in the handling of food, while the chemists taught processors how to preserve it safely. Refrigeration made possible a diet including fruits and green vegetables at all seasons. Nutritionists began nailing down some scientific facts as to what constitutes a good diet—they have no more finished their task than have the chemotherapists—and dietitians by the thousands emerged in a new profession to demonstrate these facts in many situations ranging from the factory lunchroom to the high school class of future housewives.

The Phipps Institute was born at one of the most exciting periods in the whole history of public health and preventive medicine. American living standards were being sharply raised and health standards along with them. There is no doubt that each set of conditions interacted upon the others and that hundreds of thousands of persons susceptible to tuberculosis yet not acquiring the disease were the beneficiaries.

Those who have devoted their lives to the control of tuberculosis have had valid cause for pride as they have watched the great downward curve of mortality from this disease. When the Phipps Institute was established 50 years ago, the "Captain of the Men of Death" was killing Americans in the most productive period of their lives at a rate more than 10 times greater than today. Today the world is convinced that tuberculosis is conquerable—convinced by demonstration rather than exhortation. Great minds, great hearts, great leadership, and great moneys have been rallied to this cause. Now, in 1953, the target has become measurable. The goal of eradication in this country and in our time is now attainable—at least to the optimist. And nobody but an optimist has any business in public health at all, in any of its branches.

Contributions by Nonmedical Men

The golden anniversary of the Phipps Institute represents, to my mind, an important factor in the progress of public health, but one often forgotten when the laurel wreaths are distributed and the accolades bestowed. It illustrates the great part played by laymen of vision, generosity, and courage who have contributed as greatly to the control of tuberculosis as has the brilliant work of scientists.

Many of the names are forgotten. One needs to dig below the surface in the history of this Institute, for example, to learn that when Henry Phipps in 1901 sought advice as to useful channels for his charitable endeavors, his close friend Samuel P. Harbison, of Pittsburgh, referred him to Francis J. Torrance, then a member and later president of the Pennsylvania State Commission of Public Charities. And in due course the Phipps Institute was born into the world of scientific aspiration. No matter how substantial its support in later years and in years to come from other grants and benefactions, we must never forget that its origin was due to the advice and encouragement of practical businessmen who had the vision to look beyond the obvious and the immediate.

Administrative leadership is also indispensable. I know of no single person who contributed more to tuberculosis control, for ex-

ample, than Homer Folks, for many years secretary of the State Charities Aid Association of New York. His great gift of leadership, his capacity for organization, and his eloquent persuasiveness, along with his incorruptibility and fine intelligence, would have made him a success in any business or profession. He chose to devote his talents to the public welfare in general and to tuberculosis control in particular, for the benefit of the people of the State of New York. With Dr. Hermann Biggs, New York's first great health commissioner, to steer a steady scientific course and with Homer Folks

50 Years of Tuberculosis "Study, Treatment, and Prevention"

The past half century has been a dynamic period in the attack on tuberculosis—a time of high hopes sometimes realized, sometimes dashed, but withal a time of steady progress in the development of the basic and applied knowledge essential to the eventual conquest of the disease.

Spanning this period and contributing importantly to the record of achievement is the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis. It was founded in 1903 by the Pittsburgh industrialist Henry Phipps, whose interest in tuberculosis was stimulated by Dr. Lawrence F. Flick of Philadelphia, one of the founders of the National Tuberculosis Association. In 1909 the Institute became a part of the University of Pennsylvania.

In February of 1953 the Institute celebrated its golden jubilee, asking leaders in the "study, treatment, and prevention of tuberculosis" to share their appraisal of our present status and future prospects.

The authors and Dr. Esmond R. Long, director of the Henry Phipps Institute and director of medical research of the National Tuberculosis Association, have made these papers available to Public Health Reports in advance of their appearance in a commemorative volume. The major portion of Dr. Parra's discussion of the prevention of tuberculosis appears here, followed by a condensation of Dr. J. Burns Amberson's remarks on treatment.

—The Editors

to educate the people and their legislative representatives, the Empire State got off to a head start in public health and in tuberculosis control.

As other examples of nonmedical statesmen in public health, let me cite Frederick T. Gates and Wickliffe Rose, who guided the Rockefeller philanthropies which promoted medical education, added so much to our knowledge of preventable disease, and demonstrated so early the practicability of applying that knowledge to human need throughout the world. These are but a few among the many lay workers who have made possible the near victory in tuberculosis control and the almost complete victory against other and more vulnerable ancient plagues. Whatever our plans for the next half century, if they are to be successful, they must depend even more than in the past on citizens such as these.

Motivated in part by what Newsholm calls "the sentiment against suffering" and in part by the instinctive wisdom inherent in groups of good citizens who care profoundly and who will work devotedly for a cause outside and beyond their personal advancement, these men set forth zealously with the twin weapons of faith and hope. They had faith in our form of government, which will back with tax support measures for the welfare of the people after their authenticity has been demonstrated by voluntary pioneering. They had faith in the capacity of the average citizen to learn—to change his personal habits, if need be, in his own interest and that of his fellow citizen. They had hope that bed rest, fresh air, sunshine, and good food would help the victims of tuberculosis; that less crowding in filthy slums would lessen the spread of infection; that bovine tuberculosis could be eliminated.

Sociologists tell us how well-nigh impossible it is that people might change their habits without any specific promise that whatever they might do or might not do would save them from tuberculosis. Nevertheless, the people were motivated to action; a vast number were persuaded to do certain things and to refrain from doing others. All this, to my mind, entirely justifies the statement in the recent report of the President's Commission on the Health Needs of the Nation, "The individual effort of an in-

formed person will do more for his health and that of his family than all the things which can be done for them." You will note particularly the adjective "informed."

Current Status

Because the gains in the fight against tuberculosis have been substantial, we can accept rather cheerfully the fact that Pasteur was altogether too optimistic in his opinion that infectious disease could be banished from the earth and that Allen Krause in forecasting that the trend of tuberculosis rate would bring it to zero in 1935 was quite wrong (2). Tuberculosis we still have with us, but it is in manageable dimensions, at least as far as the Western World is concerned. Many persons now forecast that tuberculosis may become a minor cause of death in Western Europe, in North America, and in Australia before we know the reasons for this event. That would be good for humanity but a black eye for science.

By any scale of values, however, the 90-percent reduction in mortality rates in this country from 194 per 100,000 population in 1900 to less than 20 in 1951 is an outstanding performance. But there must be no complacency in our view of the tuberculosis that remains among us. It is not the time for a change in the energy and relentlessness with which the disease has been attacked. National averages are misleading. Tuberculosis mortality now is $3\frac{1}{2}$ times as high in the nonwhite population as among white citizens. Iowa and Minnesota may have rates of less than 10 per 100,000, but Alaska and Puerto Rico have rates 6 to 10 times the national average.

Even though statisticians believe that 1952 figures will show it to be ninth among the causes of mortality, and although it now accounts for only 2 percent of deaths in the country as a whole, tuberculosis is still a leading cause of death among young adults. In monetary terms, national efforts to control this disease are costing the American people more than \$350 million a year—a figure which does not take into account the cost and depreciation of hospital buildings or the training of professional personnel (3). If we try to estimate the loss in family incomes when the wage earner is separated from

his family for sanatorium care over long periods, and the fact that even though his life may be saved and his disease arrested he dares not go back to hard physical labor, the cost totals become astronomical. If one attempts to estimate the cost to the community of the broken homes so often resulting from tuberculosis either of father or mother, we would unhappily agree that tuberculosis still stands close to the top as a social tragedy, possibly exceeded only by mental disease.

Factors Affecting the Decline

Let us now consider briefly some of the reasons for the winning tide of battle thus far. We are faced at once with the paradoxical situation that not even the greatest living experts will make more than a cautious and qualified guess as to which of many relevant factors have had the greatest impact or what relative therapeutic or preventive weight may be given to any of them. A single exception to this generality is the epidemiological platitude that wherever the chain of infection is broken—whenever an early case of tuberculosis is taken out of the family, social, or business environment—x number of new cases do not develop. This single, simple fact may well be the keystone of the arch for the building of future programs.

Most experts are agreed that medical science alone cannot take major credit for the decline in tuberculosis rates, since the decline began long before control programs were initiated and before there were any scientific bases for such programs. For example, it has been estimated that the mortality rate in 1830 for the combined populations of Boston, New York, and Philadelphia was approximately 400 per 100,000 population; by 1900, this rate had dropped to approximately 250 in these three cities and to 204 in the United States as a whole.

As far back as 1937, when the mortality rate was far higher than today, Wade Hampton Frost, formerly of the Public Health Service and then of the Johns Hopkins University School of Hygiene and Public Health, expressed his belief that in this country we already had reached the stage at which the biological balance

is against the survival of the tubercle bacillus. He felt that even though measures taken up to that date to limit the spread of the bacillus in our environment were insufficient to prevent the infection of the great majority, such measures might still have great effect.

Another consideration, Frost thought, is the fact of "conditions limiting the propagation of the tubercle bacillus, which are: (a) that in order to escape from its host it must cause a lesion which breaks through the surface—in general, an extensive lesion which severely damages the host—and (b) that it succeeds in producing such a lesion in only a limited number of infected persons."

Various other pathogens of man are subject to one or another of these conditions, but none to both. The combination of these two limiting conditions constitutes the peculiarity of the tubercle bacillus which makes it more amenable to control by case isolation than are such diseases as diphtheria, scarlet fever, or measles. Consequently, Frost concluded: "Although tubercle bacilli multiply within the body, in a great many cases they do not escape to reach other hosts. Logically, therefore, for the eventual eradication of tuberculosis it is not necessary to set ourselves the impossible goal of immediate and complete prevention of all transmission. It is necessary that the rate of transmission be held permanently below the level at which a given number of infection-spreading cases succeed in maintaining themselves" (4).

This epidemiological prognosis should spur us to find more hidden cases and isolate them more swiftly from their susceptible associates. It encourages us also, in 1953, to believe that the biological balance is increasingly on our side.

Elements of Uncertainty

Nor should we disregard the elements of uncertainty which Frost pointed out, "among them, uncertainty as to the stability of our civilization." In the atomic age that has been thrust upon us since his death, we are all grimly aware that tuberculosis control, along with every other good thing our western civilization has evolved for and through its citizens, may be discarded in the event of another global war.

But assuming that our civilization stands, and assuming a continuation and improvement of environmental control, Frost saw only two forces which singly or together might check or reverse the downward trend. They were (a) a decrease in human resistance to the disease and (b) some fundamental change in the virulence of the tubercle bacillus, the specific properties of which, as he pointed out, have changed little in modern times.

As to the first of these possibilities, it might be noted that an increase in racial resistance over the centuries may be of some importance in "tuberculized" civilizations, but it does not explain the recent precipitous fall. Conversely, the low racial resistance among populations rarely exposed to infection is acknowledged. But since we assume that in the future these populations will not have similar gross repeated exposures, this fact is not of importance.

Developments Since 1937

It has been said that the level of tuberculosis mortality is a sensitive index of a complex variety of environmental factors. Since Frost made his carefully calculated predictions in 1937, a number of things have occurred in this country to affect that index. It is not possible to list these things in order of importance for, in fact, we do not as yet know with any degree of accuracy what has contributed most to the decline in the tuberculosis rate. Nevertheless, it is reasonable to assume, on the basis of experience, that each in some degree has weighted the scales more heavily against the tubercle bacillus.

1. Living standards, including standards of nutrition, have steadily improved; levels of education have risen; hours of work have lessened; general public health measures have been broadened and intensified.

2. As a result of increasingly intensive case finding, the number of newly discovered cases reached a peak of 137,006 in 1948; since then there has been a slight decline, year by year, to 118,491 new cases in 1951. Mass radiography of whole populations has become economically feasible and is being utilized for the benefit of about 14 million American citizens each year.

3. Chemotherapeutic agents have proved

helpful and may point the way toward a specific. Surgical procedures have been improved and are more widely used in appropriate cases to lessen the spread of infection and to prolong life.

4. The National Tuberculosis Act of 1944 charted a Federal policy and program for control of the disease, with States and research agencies cooperating, and authorized support for more extensive and more unified efforts.

5. A worldwide attack upon tuberculosis has been organized; the value of the BCG vaccination has been confirmed—though it is far from a complete answer for the prevention of tuberculosis—and it is being used on a broad scale internationally, especially in the war-torn and underdeveloped countries.

Quo Vadis?

At this point it is relevant to inquire, *quo vadis?* I agree with Dubos that progress does not necessarily consist of doing more and more of what has proved profitable in the past. Research is certainly needed. Even though the results may prove only that we are on the right track, research is needed to validate our going forward faster in the familiar channels.

But we cannot mark time waiting for the result of inquiries. In my opinion, these are some of the things we must go on doing at a brisk tempo, concurrently with a diversity of research:

1. Hospital beds more wisely utilized for the patients with active disease are the crux of the problem. Some waiting lists for such beds now are so long that the discovery of new cases in the absence of the means of relieving them perhaps adds to the sense of frustration.

2. More and better trained personnel are of equal importance with the provision of hospital beds. In some sanatoriums whole wings are closed for lack of professional staff. We need to recruit actively nurses, doctors, and technical personnel of all descriptions. We need to recruit an increasingly better type of student, and to make sure these are offered as good a professional opportunity in the care of the tuberculous patient as in any other area of medicine and public health.

3. Even though the disease may be eradicated

without better vaccines and drugs—merely by integrating biological wisdom with social technology in the management of everyday life—the search for the vaccine or for the drug might, in the long run, be simpler. A better vaccine or the new cure may be found. BCG and some new chemicals may be short steps in the right direction, or an entirely new direction may be indicated. Whatever the answer, the search must go on.

Exploration Needed

So far, I have been urging that we do more and that we do better some of the things already being done. Nevertheless, there are several areas in which we know very little about the potentialities for tuberculosis control and where exploration appears to be clearly called for.

For example, every student of tuberculosis is aware of the varying emphasis on diets over the years. Yet what, precisely, do we know about what types of food deficiency are or may be critical in their impact upon the patient? I am convinced only that during both world wars the lack of food was correlated with increased mortality from tuberculosis and that relief from a starvation diet was followed by a prompt reduction in mortality.

We have made general assumptions as to the relationship between “poor living conditions” and tuberculosis. Actually, we know nothing about it on the basis of scientific study.

We believe that exhausting physical work adversely affects resistance, but how we do not know. Does this factor or the working environment, or do both factors, account for the relatively higher death rate among older males? Springett maintains that despite the present form of the tuberculosis mortality curve, there has never yet been a group of men who experienced a greater mortality at ages over 45 years than their contemporaries experienced at young adult ages (5). Frost and others earlier reached the same conclusion, as the age “cohorts” of mortality were analyzed. From this evidence, can we conclude that tuberculosis deaths in later life are usually, though not always, the result of disease acquired many years earlier? In fact, it appears that the lifetime experience of any generation can be pre-

dicted from its level of mortality in the first years of life. Available evidence regarding exogenous and endogenous infections conflicts.

Even though it is not possible to change the totality of what we consider an adverse environment—in other words, we are not yet able to abolish poverty—may it not be found by careful investigation that some one factor predominates? Having found it, might it not be possible to ameliorate that one factor?

Research of this type is difficult and costly. It involves the skills of the social scientists integrated with the skills of public health and clinical scientists. The Graduate School of Public Health of the University of Pittsburgh is particularly interested in this type of study and is undertaking it in reference to certain other chronic diseases.

The Phipps Institute has pioneered in the fields of immunity and susceptibility in tuberculosis, and its experts would be the first to insist that the surface has hardly been scratched. Such work should continue, even if by some happy accident the perfect vaccine were to be discovered tomorrow, because of its contribution to our understanding of other disease processes.

We know little about the ways in which emotional stress affects resistance. That it does seems possible from the drop of the mortality curve in Japan, Germany, and Austria after the war had ended but before there were available good food, decent housing, or other factors, which in the United States we have considered basic for tuberculosis control.

Is the well-known tendency of tuberculosis to reactivate related to tension or emotional stress? Is this a factor among the infectious patients who leave the sanatorium against advice? Since 25 percent of our tuberculous veterans and an even larger percentage of civilian patients fall into this latter category, it would seem that we need scientists specializing in human behavior to integrate their skills with those of the tuberculosis epidemiologists and clinicians.

Expansion of Present Activities

Sanatorium care is the largest single debit entry in the United States control program. In

a recent review, Dr. Long very wisely suggests making more beds available for more patients by greater cooperation with the practicing physician, especially for those patients who have responded so well to hospital care and indoctrination that they may be sent home under proper medical supervision and chemotherapy (3).

This is sound in principle for several reasons: It should reduce the total cost of care, return the patient earlier to his family, and increase the interest and participation of more physicians in tuberculosis control. This last point is important, since private physicians now report only 15 percent of the new cases. Moreover, this suggestion is strengthened by the precedent of syphilis. A decade ago its treatment was practically a health department monopoly; today the private physician has taken over a very large proportion of it.

In addition to the mass X-rays, which serve as a dragnet gathering in many unsuspected cases, hospitals and clinics should be required to make a chest X-ray routinely upon every person entering for any disease condition. In view of the fact that the care of each tuberculosis patient costs, on the average, about \$15,000, every institution of diagnosis or healing should utilize every opportunity to identify another link in the chain of infection.

From my own experience in dealing with syphilis and other communicable diseases, I would suggest a much greater use of the epidemiological method. This is particularly practical in this country during the present period of transition, when a large part of the population is not exposed to tuberculosis until adult life and many not even then.

In 1900, by contrast, our environment was literally saturated with the tubercle bacillus, like fog in a valley. Not so today, when there is evidence to show that tuberculosis is kept alive by a series of local epidemics. Intensive epidemiological study can ferret out the source, the contacts, and the secondary cases not only in households but also in schools, factories, restaurants, business offices, and through the routine X-ray of all patients of hospitals and

clinics. Here are opportunities to break the chain of infection and save the maximum of human suffering and economic loss with the minimum of effort and expense. They should be explored more fully.

Steps Toward Success

It is highly commendable to have developed a more or less standard control program for tuberculosis, or any other disease entity. It will, however, become static and steadily less effective unless we constantly evaluate each part of it. We need to search endlessly for more facts, for new approaches. Even though our battle against tuberculosis has gone well, we are still at the frontiers of knowledge. I suggest, in short, more pinpointing of the predisposing and precipitating factors of the disease and their mechanisms of action, changing our emphasis as new truths become known, adding or subtracting one or another element in the program as knowledge grows and the disease declines.

"To combat consumption successfully," wrote Knopf of Philadelphia in 1901, "requires the combined action of a wise government, well-trained physicians, and an intelligent people." I doubt that his prescription for success can be bettered today. In this time we have set for decision, we have nothing to fear except complacency and dogmatism, nothing to avoid except inflexibility or inaction, and everything to hope for in a greater half century than the one just past.

Treatment of Tuberculosis

By J. BURNS AMBERSON, M.D.

THE INTRODUCTION of streptomycin into the clinical treatment of tuberculosis in 1944 and the subsequent use of other drugs have led to radical changes in the management of this disease. Indeed, there has been no other comparable period in its history. The momentum originally imparted by the discovery of antituberculosis drugs is still felt, and it would be rash to predict when or where it may spend itself, so swift is the rush of events. It seems prudent, therefore, to characterize the following remarks as more of a commentary than a critique.

In the relatively short time since tuberculous patients first received streptomycin, it has been found possible, by adjusting the dosage and combining its administration with that of para-aminosalicylic acid, to circumvent most of its serious toxic properties, as well as to prolong the antimycobacterial effect through many more months than either drug would accomplish alone. There are now a number of other active

antituberculosis drugs, the most potent of which are isoniazid and viomycin. Consequently, the variety of drug combinations which may be used simultaneously and in sequence becomes large and the task of assessing their efficacy quite formidable.

An accurate evaluation can be arrived at only after patient and sustained efforts in the laboratory and clinic, which will require years. Eagerness for progress should not be permitted to disrupt the methodical, time-consuming pursuit of scientific facts upon which clinical practice ultimately must stand. In dealing with a problem as complex as tuberculosis, a get-wise-quick approach is thoroughly unsound.

Early Favorable Effects

Largely because of the use of specific drugs, the early response of the tuberculous patient to treatment can now be said to be more uniformly favorable, more certainly predictable and, on the average, more rapid than ever before. Whatever the regimen adopted, the first maneuver in treatment is to attempt, as rapidly as possible, to suppress the activity of the tubercle bacillus and thus halt active, progressive disease. The effect of successful treatment is manifested by an abatement of toxemia—allowing the patient to recover his strength and feeling of well-being—and by a gradual restoration of normal physiological processes. Another easily observed effect is the retardation or arrest of active inflammation and destruction of tissue.

The early favorable effects of treatment are often conspicuous. The cough and expectoration may disappear, and drainage from discharging sinuses may dry up completely. The

Dr. Amberson is professor of medicine at Columbia University College of Physicians and Surgeons, attending physician at Presbyterian Hospital, and visiting physician in charge of the chest service at Bellevue Hospital. He received the 1952 Trudeau Medal Award partly for work begun in 1926 and reported in the October 1931 issue of the American Review of Tuberculosis. Discussing the failure of a clinical trial of sanocrysin, a gold salt, Dr. Amberson described the criteria he used to judge the clinical effect of this chemotherapeutic agent against pulmonary tuberculosis. His outline of minimum "clinical, laboratory, and X-ray observations sufficient to warrant any reasonable conclusion from such a study" is as valid now as it was in 1931.

subsidence of inflammation may also be followed by a resolution and absorption of inflammatory products which is remarkable or even dramatic. All this may be observed in the space of 3 or 4 months. But then further regressive changes of the lesions often tend to occur more slowly, and a time may come, perhaps after many more months, when little or no further change is observed, even though the symptomatic recovery is maintained.

Although the early halting of active inflammation and of exudation in and discharge from tuberculous lesions may not be synonymous with the death of the bacteria responsible, these favorable changes nevertheless benefit the patient. At the peak of these effects, necrotic lesions sometimes can be removed surgically without great operative risk. Therefore, one may think of the drying out of lesions as one of the most beneficent, rapid, and striking effects of specific drugs.

Drug Therapy vs. Rest Treatment

The mechanisms of healing under the influence of specific drugs do not appear to be essentially different from those occurring under natural conditions, often favored by a regimen of rest. With minor exceptions, the difference in the early response to treatment does not seem to be qualitative but, rather, a matter of speed and predictability. Thus, the question is raised as to whether these new developments justify or necessitate a change in our ideas regarding the use of rest treatment, which long experience has proved so helpful against tuberculosis.

An answer is difficult because of our limited knowledge of the way in which rest treatment exerts its favorable effects. These effects are vaguely identified as biochemical, hormonal, and general, but not primarily mechanical. Innate factors seem to be vital, and there is reasonable assurance that in most patients these can be raised to better levels by rest treatment and other general measures. If this be so, can specific drug therapy in any way substitute for rest? Certainly, during the early phases of active, progressive tuberculosis, when resistance is low, it seems rational and obligatory to give the patient the benefit of every

available help. It is rather generally agreed, therefore, that rest treatment and general adjuvants are just as important as the administration of drugs, and in many cases probably more so.

Measuring Resistance

Since there is no accurate objective measure of resistance, it is necessary to estimate it almost entirely by clinical judgment based on experience. Although the early response to drug therapy is in most cases consistently favorable, the tendency to relapse after the discontinuance of therapy varies widely in different patients, and this tendency almost certainly is related in part to the level to which resistance has risen. It is much easier, therefore, to identify the time and circumstances initially calling for drugs than it is to identify the time to stop them. In some patients, an early relapse indicates that chemotherapy has been stopped prematurely; in others, it is continued for an unnecessarily long time, ostensibly for safety's sake.

This dilemma illustrates the practical problem of the physician and his patient, who perforce cannot wait for the laboratory to produce a reliable test of resistance. The best test we have now is the tolerance of the patient for gradually increasing activity, especially physical exercise. And since resistance is the only permanent defense against the infection, it is logical to stop chemotherapy (at a time when healing of the disease is judged to be well advanced) before allowing the patient unrestricted activity, and then gradually to test his tolerance of greater liberty under carefully observed conditions. Justification may be found for speeding his return to a productive life or to more prolonged and radical treatment. This is another one of the problems which require long and careful study.

Condition of Tubercle Bacilli

A word should be said about the condition of the tubercle bacilli which remain in tuberculous lesions, particularly those of a solid necrotic character, after the patient has recovered and his disease is called arrested or inactive. It

has long been recognized, on the one hand, that the bacteria may survive there for many decades while the patient remains well. Should a relapse occur, these survivors or their descendants are usually found to be the culprits. On the other hand, the bacteria may eventually disappear from the lesions or, if persisting, they may be found incapable of growth on artificial culture media or of causing disease in susceptible animals. A very lively question at the moment is whether the remaining bacilli are really dead, leaving behind only their skeletal remains, or whether they have merely been so enfeebled and modified by the antagonistic forces of nature that they are unable to keep their tenuous hold on life except in the lesions in which they are found.

How long is required under natural conditions for such changes to occur is largely conjectural, but usually it seems to be a matter of many years. It now appears that the continuous administration during many months of combinations of specific drugs such as streptomycin and para-aminosalicylic acid sometimes exerts similar effects on the bacteria. This observation tempts the most critical scientist to entertain the thought that the bacteria may have been killed by the drugs. It is legitimate to pursue the thought and this is being done in various laboratories. Meanwhile, it seems wise and sound to take the position that sterilization of lesions by drugs has not been proved.

Treatment Principles

In sum, it may be said that even though the patient profits greatly from the use of specific drugs when they are needed and may experience an early halting of serious disease which in earlier days almost always led to chronic illness at best and early death at worst, his ultimate prospects of permanent recovery depend largely on other help which may be given him. Particularly they depend on the effect of rest treatment to build up his resistance for the long battle against the tubercle bacilli which survive in his tissues.

If resistance against infection has risen to a high level during treatment and the residuals of disease are small, the prognosis for permanent recovery is excellent. The recovery un-

der drug treatment of patients whose resistance is poor usually is followed sooner or later by relapse. However, surgical removal of the grossly damaged tissue, if practicable, may effectively turn the balance in such a patient's favor. Obviously, therefore, each case must be considered according to its individual features.

Certainly, a most important principle is to treat the patient with recently developed and limited tuberculosis promptly and sufficiently long to prevent extensive destruction of tissues and chronic disease and to insure the best prospect of permanent recovery. Many of these patients have no symptoms, and their disease is discovered in case-finding surveys or in other routine examinations. Although the rest cure alone has been effective in a great majority, the time required has been long, often a year or more. Now, although recovery may not be speeded greatly by drugs, their use when needed should help assure a permanent arrest of the disease almost uniformly; only a few of such patients will require surgery.

In the more advanced and active cases, reliance is now placed chiefly on the immediate and prolonged use of combined drug therapy to gain early control of the infection and to permit resolution of inflammatory changes. Mechanical procedures such as thoracoplasty and artificial pneumothorax are usually reserved for mechanical problems such as residual unhealed cavities in the lungs. Similarly, surgical resection is preferably reserved for the time when the disease has been brought under control and the remaining problem is the threat of relapse. During this time of waiting, it is to be hoped that the resistance of the patient may rise to a maximum level under treatment so that the permanence of his recovery may be improved or assured.

Another debatable question is the place of the so-called ambulatory treatment. If this could be shown to be adequate, the obvious advantages are that the huge cost of hospital care would be reduced, the patient's morale possibly would be improved, and the patient would not suffer the usual heavy social and economic losses. It is questionable whether these theoretical advantages can be achieved without paying the price of frequent relapse or of long chronic disease

leading to disability and eventually to death. Certainly, the matter should be approached objectively. Almost every conceivable treatment of tuberculosis has been applied in the past to the ambulatory patient. The early favorable response frequently is deceptive, and the opportunity to bring about a permanent recovery is easily lost.

Patients as Sources of Infection

Tuberculous patients with long-established chronic disease who circulate and act as sources of infection in the community represent a serious situation everywhere. As life is saved or prolonged by treatment, the death rate drops but the number of living patients continues to be high, and in fact, rises in some groups, particularly elderly men. Since many of these patients are destined for continuing chronic and eventually fatal disease, the problem of eliminating the source of infection short of the death of the patient must be considered. Giving drugs and thus drying up pulmonary cavities appeals to the imagination as a practical public health measure, and studies of this possibility are under way.

Here again, the only reasonable attitude is an objective one. Thus far, no combination of drugs has proved permanently adequate in preventing open cavity lesions from discharging bacteria. Furthermore, when a dry cavity

again becomes wet and starts discharging and the patient again starts coughing, he may be spreading drug-resistant strains which, when they infect a previously uninfected person, may produce disease which will not be amenable to drug therapy. The hope would be to circumvent this by resorting to different series of drugs, but the practical feasibility of this course is at best open to debate.

Prospects for the Future

In view of our better understanding of the various modes of treatment and of the outlook for the discovery of new drugs, the future holds brightening prospects for the tuberculous patient. To indulge in the hope of eventually finding an absolute and final cure of the disease would be idle at this time. The methods of study and investigation promising to lead to further knowledge are well known, but the time they require is necessarily long. One thing is certain, though: Progress will be made in laboratories and clinics like those of the Henry Phipps Institute, and the scientists who will achieve that progress will be of the same sterling character as that group at the Phipps which has given it such an illustrious past. We place in their hands, and in those of similarly competent and devoted workers, the privilege and responsibility of coming to grips with the almost limitless problems that remain.

Institute for Federal Hospital Administrators

The seventh Inter-Agency Institute for Federal Hospital Administrators will be held at the Walter Reed Medical Center, Washington, D. C., from October 26 through November 13, 1953. Participating in the institute will be key hospital administrators of the Army, Navy, Air Force, Veterans' Administration, Public Health Service, and the Bureau of Indian Affairs.

Speakers from Government agencies, schools of public health, and university departments of hospital administration will lecture and hold discussion sessions. Individual hospital problems will be analyzed.

International Certificates Of Vaccination

A revision of the immunization form required for international travel was made available in July 1953 by the Public Health Service.

Titled "International Certificates of Vaccination," and approved by the World Health Organization, the revised form provides travelers with a record of their compliance with the vaccination requirements of all nations governed by the International Sanitary Regulations. It contains certificates for vaccination or revaccination against smallpox, cholera, and yellow fever and has space for recording other immunizations such as typhus, typhoid-paratyphoid, plague, and tetanus. The principal changes are:

Smallpox and cholera certificates must bear the approved stamp called for on the certificates. The signature alone of the certifying officer is not acceptable, nor does it make the certificate valid. (In the United States, the approved stamp is that of the local or State health department in the area where the immunizing physician practices, of the Department of Defense, or of a designated yellow fever vaccination center, or it may be the seal of the Public Health Service. If the local health officer does not have an identifying stamp, undoubtedly the State health officer can validate the certificate.)

Only the primary vaccination for smallpox must be inspected and the results recorded. On revaccination, the smallpox certificate is immediately valid, whereas previously a 14-day wait was required.

The cholera certificate becomes valid beginning 6 days after the first injection or immediately in the instance of revaccination. Previously, the entire injection series had to be completed before the certificate became valid. (In the United States, two injections are given

for the initial series. Travelers are advised to take the second inoculation because the type of vaccine used in this country provides maximum protection only after the second injection.)

The period of validity for the yellow fever vaccination certificate has been extended from 4 to 6 years. (In the United States, yellow fever vaccination certificates are valid only when the inoculation is obtained from a yellow fever vaccination center designated by the Public Health Service. The international regulations require a nation to designate specific vaccination centers for this purpose and to use vaccine approved by the World Health Organization.)

The text is printed in both English and French, but entries may be completed in either language.

The new form is distributed with all passport applications issued by the clerks of the court in any city in the United States and by the passport agencies of the State Department in Boston, New York City, San Francisco, New Orleans, Chicago, and Washington, D. C. It may also be obtained from local or State health departments and from Public Health Service facilities. It is identified by number as PHS-731, revised November 1952. Copies may be purchased from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C., for 5 cents each, or \$2.50 a hundred.

Travelers to countries where passports are not needed but where immunization is required may also obtain the form from the above sources.

Although the new form replaces the previous International Certificate of Inoculation and Vaccination, the old form will be acceptable in international travel until the expiration date of recorded examinations. Also, agencies still holding stock of the old form may continue to distribute it until the supply is depleted. Inquiry concerning use, distribution, and availability of the new form and restrictions on the use of the old certificate should be directed to the Division of Foreign Quarantine, Bureau of Medical Services, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington 25, D. C.

*Prepared by the Division of Foreign Quarantine,
Bureau of Medical Services, Public Health Service.*

Distribution of Hospital Nursing Services

By HELEN G. TIBBITTS, M.A.

THE NEED FOR more nurses in hospitals is a familiar problem. As a result, sometimes hospital beds have been closed, but more often the available nursing services have been spread more thinly over the existing patient load. The American Hospital Association reports that at the end of 1951, nearly 14,000 hospital beds were closed for lack of personnel and that job vacancies existed for 22,486 graduate nurses (1), 10 percent of the total number already employed in hospitals. These data, collected by the American Hospital Association, cannot be used to show the amount of nursing care patients are receiving, but data from the 1951 American Medical Association's census of registered hospitals can be used for this purpose, and so round out the picture.

The American Medical Association has made available to the Public Health Service unpublished data on patient census and nursing personnel, which show the geographic locations and hospital types in which those patients are concentrated who are receiving less care than the nursing profession's standards recommend. Such standards have been set forth for three distinct types of hospitals: general and allied special, nervous and mental, and tuberculosis. For general and tuberculosis hospitals the standards are in terms of hours of care per patient-day, and for mental hospitals they are in terms of a nurse-patient ratio. While the nursing profession recognizes that these stand-

ards are not based on adequate data, they are the only guidelines available at this time. The standards are in fairly general use pending the results of studies now under way or contemplated.

Nurse-patient ratios have been computed for each type of hospital from data supplied by the American Medical Association. The nursing personnel included in these ratios are limited to nurses available to give direct care to patients. General duty nurses are the only professional nurses included. The nonprofessional personnel include practical nurses, attendants, nurses' aides, and orderlies. The care given by student nurses is excluded from the nurse-patient ratios developed from the American Medical Association data. The personnel counts are as of a particular day in October 1951, while the number of patients was counted as the daily average patient census for the most recent 12-month period for which data were available at that time. An adjustment is made for part-time general duty nurses so that personnel counts would be on a full-time basis. No adjustments are made for care given by private duty nurses, and to offset this, no adjustments are made for newborn census.

The ratios computed from the data for hospitals registered by the American Medical Association have been converted by a very simple process into estimates of average hours of care received by patients: For hospitals whose nurses work an average of 44 hours a week and 48 weeks a year, the average hours of care per patient-day is one-seventeenth of the number of nursing personnel per 100 patients. For hospitals that average a 40-hour week, the average hours of care is one-nineteenth of the ratio. For example:

Mrs. Tibbitts was statistical analyst with the Division of Nursing Resources at the time this study was made. She is now with the Health Resources Staff of the Office of Defense Mobilization.

Figure 1. Estimated daily hours of total nursing care per patient in nongovernmental general hospitals, 1951.

Estimated Daily Hours of Care 44-Hour Work Week

In States where nurses work 40 hours a week, each nurse works 1,920 hours per year (40×48). The number of patient-days per year is the product of 365 multiplied by the daily average patient census. If we let R stand for the number of nursing personnel per 100 patients, C stand for the average hours of care per patient-day, NP for the total number of nursing personnel, and $DAPC$ for the daily average patient census, the following relationships can be stated:

$$(1) R = \frac{100NP}{DAPC} = 100 \frac{(NP)}{(DAPC)}$$

$$(2) C = \frac{1920NP}{365DAPC} = \frac{1920}{365} \frac{(NP)}{(DAPC)}$$

$$(3) \frac{R}{100} = \frac{NP}{DAPC} \text{ (from 1 above)}$$

$$(4) C = \frac{1920}{365} \times \frac{R}{100} = \frac{R}{19}$$

Data are shown in this report in terms that make them comparable to professional standards for nursing service for each of the three types of hospitals. Comparisons are made be-

tween the staffing of Federal hospitals, other governmental hospitals (includes those administered by the Bureau of Indian Affairs), and nongovernmental hospitals for each of the three types of service. Where figures are quoted in terms of hours of care given, they are based on the assumption that nurses in Federal hospitals work a 40-hour week and that nurses in other hospitals average a 44-hour week.

General and Allied Special Hospitals

The variations in hours of nursing care per patient-day available in hospitals under different types of control and the number of patients affected are as follows:

Control	Patients (in thousands)	Hours of care ¹	
		Total	Professional
Federal.....	96	2.1	0.7
Other governmental....	119	2.8	.9
Nongovernmental.....	294	3.6	1.6

¹ Reference 9.

Figure 2. Estimated daily hours of professional nursing care per patient in nongovernmental general hospitals, 1951.

Estimated Daily Hours of Care
44-Hour Work Week

This picture of the situation in general hospitals shows that patients in Federal hospitals and those in other governmental hospitals are receiving not more, but actually less, nursing care than are patients in nongovernmental hospitals.

The average length of stay of patients in Federal hospitals is about three times as long as in nongovernmental hospitals. Long-term patients usually need less nursing care than short-term patients. However, obstetrical cases make up about one-fifth of the admissions to nongovernmental hospitals and only one-fifteenth of the admissions to Federal hospitals, and such cases are characterized by shorter than average stay and less than average acuity. Furthermore, in Public Health Service hospitals (data are not at hand for other Federal hospitals), the median length of stay is only about one-half the average stay; and of the 80 percent of patients who are discharged in less than 1 month the

average stay is considerably less than one-half the average stay of all patients.

If an adjustment were made for the care given by student nurses, the difference between the amounts of nursing care available to patients in governmental hospitals of both types and those in nongovernmental hospitals would be more pronounced.

Information from other sources indicates that on a national basis student nurse care averages about 0.5 hour per day for each patient in general hospitals, and that 86 percent of it is concentrated in the nongovernmental hospitals. The breakdown of these figures follows:

State surveys made by the Division of Nursing Resources, Public Health Service, corroborated by evidence from the 1950 list of State Approved Schools of Nursing, indicate that a student nurse gives care to patients .4 as many hours as a graduate nurse employed on a full-time basis by the hospital. This means that the 102,500 students enrolled on January 1, 1951, were spending as many hours giving care to

patients as 41,000 full-time nurses employed by the hospitals, or 86,592,000 hours a year, based on average personnel policies in nongovernmental hospitals. The 509,446 patients in general and allied special hospitals received 185,047,790 days of care in the year, or .47 hours per patient-day from student nurses.

The concentration of student care in nongovernmental hospitals can be inferred by the control of the hospitals operating the schools in which the students are enrolled. Of the 97,903 students reported in Facts About Nursing to have been enrolled in schools of nursing January 1, 1950, 13,561 were enrolled in schools operated by Federal, State, city, county, or city-county hospitals. The control of the hospitals with schools was determined from the list of hospitals registered by the American Medical Association, and their enrollments from the 1950 list of State Approved Schools of Nursing.

A conservative estimate is that patients in nongovernmental hospitals probably average .4 hour of care daily by student nurses, which brings the total hours of care they are receiving up to 4 a day, about one-half of it being professional.

The average staffing of nongovernmental hospitals, computed by totaling personnel and patients in this entire group of hospitals, appears to meet the standards set by the nursing profession in 1948 with respect to total hours of nursing care although not in number of professional nursing hours. A study published by the National League of Nursing Education in that year indicated that each patient should have 3.5 hours of care per day, with 2.4 of these hours provided by professional nurses (7).

A more recent study indicates that under specified conditions of assignment and supervision professional care may be sufficient if it is one-third of the total (6), and another shows that patients on active medical and surgical service require 3.9 hours of care (10). A definitive study is needed now to relate amounts of nursing service to the demands of modern medical practice, but in the last analysis each hospital has, and will continue to have, different requirements.

The staffing ratios presented here are averages for large groups of hospitals; and hence, as would be expected, many hospitals in any group will have ratios lower than the group average. The extent to which nongovernmental hospitals fail to meet the standards of the nursing profession for general hospitals is sketched

in briefly following the discussion of geographic variations.

Nervous and Mental Hospitals

Patients are distributed among the three classes of nervous and mental hospitals in inverse relationship to the amounts of nursing care available:

Control	Patients (in thousands)	Nursing personnel per 100 patients ¹	
		Total	Professional
Federal-----	60	26.2	2.9
Other governmental---	621	11.5	.3
Nongovernmental----	17	33.9	4.2

¹ Reference 9.

In contrast to the situation in general hospitals, patients in Federal mental hospitals are receiving considerably more care than patients in other governmental hospitals. It remains true that patients in nongovernmental mental hospitals are receiving the most care.

The standard approved by the American Psychiatric Association in 1945 for staffing mental hospitals called for 4 professional nurses per 100 patients, and 25 nonprofessional nursing personnel (4). The great majority of mental patients in the hospitals operated by States and other local governments thus is receiving less than one-tenth the professional nurse care and only two-fifths of the total amount of care considered essential.

While on the face of it, the average staffing ratios of nongovernmental mental hospitals appear to meet the standards quoted, it must be realized that these hospitals generally are undertaking intensive therapy for a much larger proportion of their patients than the State mental hospitals for which the standards were designed. The American Psychiatric Association has since developed a more discriminating set of standards, but they can be used only in a situation in which something is known of the condition of the patients in addition to their total number (3).

Tuberculosis Hospitals

The patient with tuberculosis receives the most care in a Federal hospital, and the least care if he is in a nongovernmental hospital:

Table 1. Average hours of nursing care by all types of nursing personnel, except student nurses, per patient-day and distribution of hospitals according to actual hours provided: nongovernmental general hospitals in 8 States

State	Average hours	Hospitals distributed by actual hours care					
		Total	Less than 2.0	2.0-2.9	3.0-3.9	4.0-4.9	5.0 and over
Arizona.....	4.3	11	-----	1	3	3	4
District of Columbia.....	4.2	12	-----	1	5	5	1
Maine.....	3.2	28	3	3	12	7	3
Nebraska.....	3.9	71	1	11	25	12	22
New Mexico.....	3.8	18	1	4	6	2	5
South Dakota.....	2.9	35	2	6	15	7	5
Vermont.....	3.4	18	1	6	3	6	2
West Virginia.....	3.1	48	2	8	21	14	3

Control	Patients (in thousands)	Hours of care ¹	
		Total	Professional
Federal.....	8	1.8	0.6
Other governmental....	58	1.4	.2
Nongovernmental.....	8	1.2	.2

¹ Reference 9.

On the basis of standards of the Tuberculosis Advisory Nursing Service, even the better staffed Federal tuberculosis hospitals are short of professional nurses (5). These standards are based upon the regimen prescribed for patients, that is, whether the patient is on strict bed rest, bed rest, or is semiambulant, or ambulant. To obtain a single figure from these four standards so that comparison could be made with existing staffing practices, the nursing requirement of patients in each category was weighted by the probable proportion of all patients in the category. The weighted average nursing requirements of tuberculosis patients amounts to

a total of 1.8 hours of care per day, .9 hour of which should be professional nurse care.

Geographic Variations

All of the figures cited so far have been national averages. It is reasonable enough to use national averages when discussing Federal hospitals since their centralized administration means that there is relatively little local variation in staffing ratios.

What justification is there, however, for computing a single ratio by combining data for 48 States from Arkansas to Maine and from Georgia to California? A comparison of the ratios for nongovernmental general hospitals across the country suggests part of the answer (9). Figure 1 shows some geographic variations in the ratios of total nursing personnel to patients. The ratios have been grouped into

¹ Only one hospital operates a school of nursing, and to avoid disclosing confidential information, data are not shown.

four classes for mapping purposes. The States with the lowest ratios have fewer than 55 nursing personnel of all types available to care for each 100 patients. This means that in these States if nurses work 44 hours per week, patients can receive an average of less than 3.2 hours of care per day. Patients in the next higher States can receive 3.2 to 3.7 hours; in the next to the highest group of States they can receive 3.8 to 4.0 hours, and in the highest States, 4.1 hours or more are available.

Figure 2 shows similar variations in graduate professional nurse to patient ratios. In the States with the lowest ratios, fewer than 22 graduate professional nurses care for each 100 patients. That is, patients in these States can average less than 1.3 hours professional nurse care each day. Patients in the next group of States can average 1.3 to 1.9 hours professional nurse care daily, in the next higher group, 2.0

to 2.5 hours, and in the most privileged States they can average 2.6 hours or more.

Interhospital Differences

It cannot be inferred that a State whose average nurse-patient ratios provide for amounts of care that meet professional standards has all the nurses it needs in its hospitals. Nurses are not distributed among all hospitals in proportion to the number of their patients, and no assumption is made that this should be so (tables 1 and 2). Admittedly, the patients in some hospitals need more care while those in other hospitals may need less, depending upon the conditions for which they are being treated, the nature of the treatment, and the hospital's program.

The safest assumption probably would be that the patients in any general hospital need at

Table 4. Hospitals distributed according to total hours of care provided per patient-day, including care given by student nurses: nongovernmental general hospitals in 8 States

State	Total hospitals	Total hours care				
		Less than 2.0	2.0-2.9	3.0-3.9	4.0-4.9	5.0 and over
Arizona.....	11	-----	1	3	3	4
District of Columbia.....	12	-----	-----	6	5	1
Maine.....	28	2	4	9	7	6

New Mexico.....	18	2	4	6	2	4
South Dakota.....	35	2	8	12	8	5
Vermont.....	18	-----	1	8	7	2
West Virginia.....	48	2	11	20	10	5

least the amount of care that would be equivalent to the nursing profession's 1948 standard for total hours of care and Bredenberg's standard for hours of professional nurse care. The corollary of this assumption is that hospitals providing more hours of care than this do so either because of the kind of care their patients need, out-of-date facilities for care, awkward administrative procedures, educational programs for student nurses or medical students, or for a variety of other possible reasons. Thus, in Nebraska, although the State average meets professional standards for total hours of care, at least 12 hospitals could be considered inadequately staffed.

Differences in the extent to which student nurses give patient care show up in table 3. Table 4, when compared with table 1, shows how including the care given by students in the total hours affects the picture of the amount of care patients are receiving.

Summary

1. The ratio of nursing personnel to patients in the entire group of nongovernmental general hospitals in the country is sufficient to provide an average of 3.6 hours of care, 1.6 hours of this being professional. Nevertheless, numerous hospitals in every State need more of both categories of nurses even where statewide ratios are at the national average. Only in the Pacific coast States and in Nevada, Wyoming, and Florida do patients in general hospitals appear to be receiving an average amount of both professional and nonprofessional nursing care that is up to minimum professional standards. In the New England States the average amount of professional nursing care appears to be sufficient, but hospitals in this area perhaps should employ more nonprofessional nursing personnel. In all of the remaining States there appear to be too few graduate nurses in the general hospitals.

2. All general hospitals under governmental control of any sort appear to be short of both professional and nonprofessional nursing personnel, although the longer average length of stay in Federal hospitals modifies the picture to some extent.

3. In the mental hospital field, only those under nongovernmental auspices come close to meeting the staffing standards of the nursing profession, and these hospitals care for only 17,000 of the 698,000 patients in this kind of institution.

4. Tuberculosis hospitals in all three classes appear to be grossly understaffed with respect to both professional and nonprofessional nurses.

Occupational Disease Reporting

By VICTORIA M. TRASKO

THE STUDY and control of occupational diseases in the United States has progressed markedly in the past four decades. A vast body of information, both clinical and toxicological, has been developed, particularly on such diseases as silicosis, dermatoses, and poisoning due to lead, benzol, beryllium, and hundreds of other toxic substances. Scientific knowledge concerning the environmental control of these diseases is likewise well developed, although its application is yet far from universal. An exception to these notable gains has been the ineffectual attempt to obtain adequate morbidity data on occupational diseases.

The value of universal morbidity statistics on diseases, whether communicable, chronic, or occupational, is unquestioned in public health planning, in developing control programs, and in aiding the passage of pertinent legislation. Though incomplete, statistics based on early pioneering studies of occupational diseases and general sickness have been sufficiently impressive to interest governmental agencies and other groups in the improvement of working conditions and in raising the health level of workers.

Miss Trasko, public health adviser to the Division of Occupational Health, Public Health Service, and a member of the division's staff since 1938, has had varied experience in industrial hygiene activities in this country and South America.

This paper is based on Public Health Service Publication No. 288, Occupational Disease Reporting—A Review of Current Practices, Together With a Collection of Incidence Statistics, also by Miss Trasko. Detailed analyses of the information presented in this article will be found in the full publication, now in press.

In fact, the recognized prevalence of silicosis and its association with tuberculosis was one of the main reasons for the establishment by the Public Health Service of an "office of industrial hygiene and sanitation" in 1914.

Despite their limitations, occupational disease statistics have also influenced the adoption of legal measures to control the use of toxic substances known to cause illness among exposed workers, and to regulate general working conditions. Beyond that, however, the absence of reliable data on the prevalence of occupational diseases has made impossible a definition of the overall industrial disease problem and a reasonable determination of where toxicological and clinical research is needed.

Industrial hygienists have long recognized this hindrance, and representatives of State and local industrial hygiene units, medical directors of private industries, representatives of insurance companies, and others have, for many years, urged the Division of Occupational Health of the Public Health Service to undertake a study of the prevalence and reporting practices of occupational diseases in the United States. Finally, because of the long-sustained need and in view of the fact that the situation was remaining static, such a project was undertaken in 1949.

One of the phases of this project dealt with a review of the status of required reporting by physicians to State and local agencies. The second phase dealt with an experimental pilot study originally undertaken to test the feasibility of developing a national reporting system for occupational diseases. In addition, the project has also encompassed the collection of all available statistics on occupational diseases.

Required Reporting of Occupational Diseases

An accepted method of obtaining information on the incidence of diseases is through required or universal reporting by practicing physicians. While a fair degree of success may have been experienced through the reporting of communicable diseases, required reporting on the whole is not considered an effective device. For occupational disease statistics and prevention purposes, this method has produced discouraging results.

The idea has been expressed that required reporting will never be successful unless it is associated with reasons other than that of collecting statistics (1,2). The administration of workmen's compensation laws in this country provides this incentive, since the reporting of essential information concerning the cause and nature of accidents and diseases is required of the physician, employer, and worker before benefits can be paid for the disability incurred. There is no doubt that reporting for compensation purposes is more successful, at least quantitatively, than compulsory reporting, despite the relatively long reporting experience in this country and the fact that more than one-half of the States require reports.

At the present time, 27 States have legislation or regulations requiring physicians to report one or more occupational diseases to health or labor authorities. According to available information, several States, including New York, Michigan, and Wisconsin, passed their first laws in 1911. The Maryland law was first enacted in 1912; the New Hampshire law, in 1913; and the Rhode Island law, in 1915. Ohio requires reports to both the State department of health and the industrial commission. The department of health law dates to 1913 and the industrial commission law, to 1921. While many of these earlier laws have been revised and broadened, a few are still in force in their original forms. About one-half of the 27 States that now have laws or regulations enacted them after 1936, when the passage of the Social Security Act made funds available for the establishment of public health programs, including industrial hygiene. These reporting laws were passed to facilitate the efforts of the State industrial hygiene agencies in obtaining occupa-

tional disease reports for investigative purposes.

Many reasons are attributed to the ineffectiveness of required notification of occupational diseases. Among these are difficulties of recognition and diagnosis. Limited knowledge of occupational diseases, of industry itself, and of materials handled and manufacturing processes involved contribute to lack of reporting. Moreover, it is probable that many physicians are of the opinion that reporting occupational diseases violates the confidence of the physician-patient-employer relationship. Other factors are lack of standardization, nonenforcement, and other shortcomings of the laws themselves.

Reportable Diseases

Contrary to the practice in communicable disease reporting, there is no standardized pattern among the States for occupational disease reporting. For instance, all occupational diseases, with or without definitions and qualifications, are reportable in eight States (Georgia, Louisiana, Massachusetts, Michigan, Mississippi, Montana, South Carolina, and Utah). In six States (Alabama, Arkansas, Colorado, Iowa, Missouri, and New Mexico) the reportable diseases are named. In Arkansas, the list corresponds to the schedule of compensable diseases covered by the State workmen's compensation law; in the other five States, the list bears little or no resemblance to the schedules, since most reporting laws were passed before occupational diseases became compensable. In two States, New Jersey and Pennsylvania, the compulsory reporting is limited to lead poisoning.

Reporting laws in the remaining 11 States appear to be patterned after the British Factory and Work Shop Act of 1895, which requires reporting by the medical practitioner of anthrax, and of poisonings by lead, phosphorus, and arsenic (3). New York and Wisconsin seem to have used this basic pattern, later adding mercury poisoning and compressed air illness to the list. The laws in the other nine States (Connecticut, Kansas, Kentucky, Maine, Maryland, Minnesota, New Hampshire, Ohio, and Rhode Island) follow the New York-Wisconsin pattern but have added poisoning due to brass and wood alcohol, and conclude with

the phrase "any other disease contracted as a result of the nature of employment."

An interesting reporting device used by Ohio, Missouri, Pennsylvania, and New Jersey is a law which requires that physical examinations be made periodically of workers exposed to certain toxic substances, and that all cases of poisoning thus found be reported both to the State health and the State labor authorities. In Ohio, New Jersey, and Pennsylvania the law applies to exposure only to lead and its compounds; in Missouri, the law is more inclusive and covers exposures encountered in the manufacturing or processing of antimony, arsenic, brass, copper, lead, and other substances.

Recipients of Reports

Another shortcoming which possibly bears on the limited success of current reporting is the lack of uniformity as to whom the reports are to be made. Legal provisions in 17 States require that reports be made to the State health officer; in 2 of these States, the local health officer is also mentioned. In 6 States, the local health officer is named as the exclusive recipient. Experience has shown that unless the local health department has its own occupational health program there is less chance that reports of occupational diseases will be made, since the incentive to encourage reports is lacking. Moreover, the few reports that might be made directly to local health departments usually reach the State industrial health agency responsible for their investigation either late or not at all, or in a summary form along with other notifiable diseases.

In Ohio, physicians are required to report occupational diseases both to the State department of health and to the State industrial commission, in accordance with separate laws. In actual practice, however, the commission receives from physicians only those reports which involve claims. In two other States, Massachusetts and New York, physicians are required to report to the State department of labor. In New Jersey, Pennsylvania, and Ohio, separate statutes make lead poisoning reportable to both the State health and the labor authorities.

Several of the State laws provide for an exchange of reports. According to the Massachusetts law, copies of reports of occupational

diseases made to the department of labor may be referred to the State department of health on request; in three States, Missouri, New Hampshire, and Ohio, copies of reports made to the State health department must be transmitted to the State labor authorities.

Extent of Present Reporting

A canvass of occupational disease reporting showed that slightly less than 1,800 cases of occupational diseases were reported by physicians to health departments during 1950 or 1951. Moreover, 1,695, or 94 percent, of these cases were reported by three States, Connecticut, Michigan, and Ohio, the rest being reported by Colorado, Kentucky, Minnesota, and Montana. Eighteen States with reporting laws received an occasional report or none at all. In fact, some of these States have never received an occupational disease report, despite continued efforts to solicit cooperation. New York and Massachusetts were not included in the above tabulations because they indicated that the reports received were too few to have any statistical significance.

A crude index of under-reporting by physicians in the past as well as at present is furnished by a few States that have kept continuous records of reports received, as contrasted with the number of occupational disease claims filed or awarded by compensation authorities. For example, in 1942, the Ohio Department of Health received 1,637 reports of occupational diseases from physicians (4). This figure may be considered fairly representative for the State, since it closely approximates the average number of reports that had been received annually by the department in the 10-year period 1928 through 1937 when 12,931 cases were reported (5). In contrast, the Ohio Industrial Commission in 1942 received 5,597 occupational disease claims for compensation. The contrast was further borne out in 1950, when the Ohio Department of Health received 482 reports from physicians and the industrial commission, 4,574 claims for compensation.

The experience in Minnesota shows similar discrepancies; 61 reports were made to the State health department in 1950, as contrasted with 1,931 cases of occupational diseases closed by the industrial commission. Michigan has had a

comparable experience. The State's present occupational disease reporting law was passed in 1937, also the date of the enactment of its occupational disease compensation legislation. Under this reporting law, according to the records of the division of industrial hygiene of the Michigan Department of Health, physicians made the following reports:

<i>Year</i>	<i>Number cases</i>	<i>Year</i>	<i>Number cases</i>
1939-----	1, 110	1945-----	793
1940-----	1, 034	1946-----	553
1941-----	1, 482	1947-----	775
1942-----	933	1948-----	613
1943-----	2, 742	1949-----	513
1944-----	1, 358		

During the 2 years, 1950 and 1951, covered by the pilot study, 1,074 reports were received, including cases uncovered during field studies and not otherwise reported, as well as cases of silicosis reported as a result of general X-ray surveys. According to the biennial report for the fiscal years 1948-50, the Michigan Workmen's Compensation Commission received reports of 1,993 compensable industrial diseases. Although the 2-year periods are not the same, these figures likewise indicate a large degree of under-reporting by physicians.

In Connecticut, figures for the 1937 fiscal period showed that physicians reported 127 cases of occupational diseases; during the same year, compensation claims were paid for 286 cases which were not among those reported (6). Comparable data for more recent years are not available. However, as a result of checking physicians' reports against compensation reports, the Connecticut industrial health agency has found that many of the later occupational diseases, too, have not been reported as required by law. It should be pointed out that the experience in Connecticut is unique because the number of cases reported in 1951 increased instead of decreasing or remaining at the same level. The number of reports generally received from physicians averages 300 a year. However, as a result of more contact with physicians during the 2 years that the Connecticut Bureau of Industrial Hygiene participated in the pilot study, the number of cases reported went up to 749 in 1951. This development certainly suggests the possibility that compulsory

reporting of occupational diseases might have some merit, if encouraged actively.

Reporting of occupational diseases to the State department of public health is not required by law in California, but this State's experience is cited to show the difficulty of drawing valid conclusions from State statistics on occupational diseases. According to the interpretation of the State Workmen's Compensation Act, all illnesses arising out of conditions of employment are defined as injuries. As such, they are compensable and legally reportable to the California Department of Industrial Relations by both employers and physicians. Of special interest here are reports made by physicians of all injuries they treat which result in a disability of 1 day or longer or require medical treatment other than first aid. The department of industrial relations has been referring all occupational disease reports of this type to the bureau of adult health of the California State Department of Health for more than 15 years. The volume of reports of occupational diseases made and referred surpasses that of any other State in the country. Annual tabulations of the bureau show that for the 1939 fiscal year, 4,231 reports of occupational diseases were tabulated; during the calendar year 1944, the number was 11,893; during 1949, it was 12,536; in 1950, 12,245; and in 1951, 14,777. Between 50 and 55 percent of the cases referred were dermatoses.

To what extent this continuing rise in the number of cases reported represents a real increase in the occupational disease problem is difficult to say. No doubt, increased compensation benefits, improved methods in handling reports, and selectivity of cases falling into occupational disease categories are factors reflecting improved figures. On the other hand, California has experienced a tremendous upswing in industrialization and, as a consequence, an increase in the labor force. This growth undoubtedly has contributed to a potentially greater problem with respect to some occupational health conditions.

The Pilot Study

The pilot study represents the only known effort at uniform collection of occupational dis-

eases over a period of time, involving a group of States with various methods of obtaining reports. The pilot study was carried out in cooperation with divisions of industrial hygiene in 11 State health departments (Connecticut, Florida, Georgia, Indiana, Michigan, Missouri, New Hampshire, Oregon, South Carolina, Tennessee, and Wisconsin), selected to afford average representation of different reporting practices. The study covered the calendar years 1950 and 1951, during which time the participating States transmitted on special forms to the Division of Occupational Health, Public Health Service, individual reports of occupational diseases coming to their attention.

The pilot study was made to determine the feasibility of developing a nationwide reporting system on occupational diseases. Originally, it had been planned to consider only required reports from physicians. When it was determined, however, that few reports were being made by physicians, it became clear that a successful national reporting scheme would have to consider other sources of reports as well. The inadequacy of sole reliance on physicians' reports has been realized for a long time by State industrial health agencies, and they are presently depending on workmen's compensation agencies for reports of cases that occur in industry. Consequently, to reflect actual reporting practices in the States, the base of the pilot study was broadened to include reports referred from workmen's compensation authorities.

During the 2-year period covered by the study, 9,058 reports of occupational diseases were submitted by the 11 States. Of this total, 77 percent consisted of reports referred to the health departments by compensation agencies. Reports to health departments by physicians accounted for only 20 percent; the remaining 3 percent comprised reports of cases encountered or reported unofficially during investigations of occupational health hazards, reports of pneumoconiosis uncovered through mass X-ray surveys, and some reports of cases taken from death certificates.

The reports received may be considered typical of the kind of reports of occupational diseases being made today. The quality varied from State to State as well as within individual areas, depending on how the report

originated. Differences cannot be ascribed to any one cause; they are due to many factors inherent in the recognition and reporting of occupational diseases. In general, physicians' reports were likely to be weak on etiology; employers' reports, on the nature of the disease. In many instances, better reports resulted when the information was abstracted from both employers' and physicians' reports. While omissions, inaccuracies, and incompleteness were found in all types of reports, they were observed more frequently in reports made in connection with claims for compensation than in others. Most unsatisfactory probably were statements on the cause or substance responsible for the occupational disease.

Occurrence in Companies

The 2 years covered by the pilot study afforded a good opportunity to observe the frequency with which cases are reported from the same plants over such a period. The distribution of companies according to the number of cases of alleged or suspected occupational diseases occurring per company, as reported by 10 States in the pilot study, is shown in table 1.

Three-fourths of the 3,654 companies reported one case, their total accounting for 36 percent of all the 7,590 reports. At the other extreme, 10 or more cases were reported by 2.2 percent of the companies and accounted for 29.7 percent of all the alleged diseases reported.

In Michigan, where physicians' reports made up the largest number, 18 companies were responsible for 703 cases. It is assumed that the

M-----	6,000	43	12	19	-----	12

same person or persons in these companies made the reports, although there may have been exceptions. Data on employment were not furnished for all 18 companies, but most of them employ several thousand workers each and have their own medical departments.

The reporting experience of 13 of these Michigan companies, all manufacturing automotive transportation equipment, revealed that there is a distinct tendency for some physicians to report only one kind of occupational disease and other physicians another kind (table 2).

Moreover, there is little relation between the number of workers employed and the number of cases reported, regardless of the type of case. Company B with an employment of 21,500 workers reported 199 cases, all of which were dermatitis. Company E with 41,000 employees reported only one case of dermatitis and 67 cases of hernia. Company L with 75,000 workers reported 75 cases of pneumoconiosis, 7 of dermatitis, and 1 of hernia. Company M with 6,000 workers reported 12 cases of dermatitis, 19 of hernia, and 12 of tenosynovitis.

The suspected incompleteness and spottiness of required reporting of occupational diseases is substantiated by these figures. Since all 13 companies are engaged in the manufacture of transportation equipment, it would reasonably be expected that more or less the same types of occupational hazards would prevail, giving rise to similar types of occupational illnesses. Even if it were assumed that all operations were ade-

quately controlled, dermatitis, hernia, and tenosynovitis would probably occur fairly universally among these industries. With respect to pneumoconiosis, however, the situation may be different since it is not known how many of the cases might have been reported by physicians in the plant and how many were picked up through mass X-ray surveys.

Incidence of Occupational Diseases

To obtain a more comprehensive picture of the nationwide occupational disease problem, the pilot study data for the 11 States covering the year 1951 only were supplemented by information from the annual reports of workmen's compensation commissions in 17 States not included in the pilot study. It was determined that in the 28 States there were 43,307 alleged or suspected occupational diseases reported in a 12-month period.

State differences in compiling statistics on occupational diseases made the summarization of this material difficult, and certain liberties had to be taken when classifying cases according to a diagnostic pattern. However, a rough classification according to diagnosis shows that diseases of the skin accounted for 54.3 percent of all occupational diseases. Systemic effects due to chemical agents accounted for 5.2 percent; dust diseases of the lungs, 4.6 percent; other respiratory disorders, 1.5 percent; disorders due to physical conditions, 9.5 percent; infective diseases, 2.7 percent; and miscellaneous conditions, 22.2 percent. Wide differences occurred in the number and kind of diseases reported from State to State, probably due in part to prevalence but in larger part to variations in legal provisions on compensation of occupational diseases and to technicalities in processing the data.

Conclusion

On the basis of the evidence presented, required reporting by physicians gives little promise of yielding national statistics on occupational diseases. In view of the long experience with required notification of occupational diseases, and the continuous inadequacy of resultant reports, the need is indicated for a

reevaluation of the principle as well as procedures of required medical reporting. On the other hand, reporting for compensation purposes offers some hope of obtaining general statistics on occupational diseases, provided that some of the obvious technical difficulties can be resolved.

A practical approach might be to suggest standards and procedures, similar to those developed by the American Standards Association on work injuries applicable to occupational diseases, which the workmen's compensation agencies and others could use as a guide and which would make more usable existing statistics on occupational diseases.

CIRCULARIZATION

of free mailing list

Now Under Way

Official and free subscribers to *Public Health Reports* this month—October—are being sent a mailing list circularization inquiry. The inquiry is not sent to paid subscribers.

Required by the Joint Congressional Committee on Printing, this circularization necessitates return of a special card confirming correctness of the address and number of copies of *Public Health Reports* received each month. Health departments, teaching institutions, libraries, and others will want to devote special attention to the circularization inquiry, as the mailing list is composed for the most part of office and position titles, rather than of individual names.

Watch for the special postal card. Complete it fully and return it promptly. Failure to respond by the date specified on the card

November 2 (domestic addresses)

will result in removal of the address from the mailing list.

Report of a Case Of Rat-Bite Fever Due to *S. moniliformis*

By ROBERT L. GRIFFITH, M.D., and
DONALD W. McNAUGHTON, M.D.

REPORTS of only 51 bacteriologically proved cases of rat-bite fever caused by *Streptobacillus moniliformis* can be found in the United States through 1951.

Yet with our ever-present rat population, this disease must be considered in the differential diagnosis of obscure febrile illnesses as well as in illnesses following a rat bite. A history of the actual rat bite cannot always be obtained. The disease may be transmitted by any rodent and also by dogs and cats. Laboratory rats, as well as wild rodents, may harbor the organism. Most of the cases have occurred in children or in men whose occupations take them into rat-infested areas. There is also the possibility of the disease being spread by food, as in the 1926 milkborne epidemic in Haverhill, Mass. This epidemic was called Haverhill fever (epidemic arthritic erythema).

The case of rat-bite fever reported here occurred in 1952 in an 8-year-old Seattle boy who was bitten on the tongue by his pet white rat. The disease has previously been reported as being acquired from white rats by laboratory workers. It is the first known case reported from the State of Washington.

It is generally considered that rat-bite fever can be caused by two distinct organisms: *Streptobacillus moniliformis*, a normal inhabitant of the nasopharynx of rats, and the spirochete, *Spirillum minus* (the disease having been originally described in Japan and called sodoku) which is present in infected eyes of rats. Both organisms may be present in the same case.

Dr. Griffith is chief of medical services and Dr. McNaughton is clinical director of the United States Public Health Service Hospital at Seattle, Wash.

Occurrence of the Disease

Watkins (1) in a complete review of the disease in 1946 found a total of 184 cases of rat-bite fever reported in the United States. Of these, 39 cases were proved to be caused by *S. moniliformis* and 41 cases, by *S. minus*. Since 1946 two cases due to *S. moniliformis* have been reported from Massachusetts and one each from Connecticut, California, Delaware, Illinois, Maryland, Michigan, Minnesota, New York, Texas, and Wisconsin.

Until 1951 no proved cases caused by *S. moniliformis* had been reported in the United States west of Minnesota and Missouri, and no clinically diagnosed case had been reported in Canada west of Montreal. In that year, one case was reported from Los Angeles and two cases from Vancouver, British Columbia (2).

This geographic distribution is, no doubt, a matter of recognition and reporting, since there is no reason to believe this worldwide disease is new to western North America. Cases of rat-bite fever caused by *S. minus* have been reported from California and Oregon.

In describing the disease, it is desirable to specify the organism involved and whether it was caused by a rat bite or by some other means of entry into the body.

Diagnosis and Treatment

Clinically, rat-bite fever due to *S. moniliformis* is characterized by septic or relapsing fever and frequently by petechial or morbilliform rash and polyarthritides. The incubation period varies from 1 to 22 days, usually less than 10 days. The primary wound generally heals rapidly. There may be regional lymphadenopathy. Leukocytosis is usually present. About 16 percent of the cases have a false positive serologic test for syphilis. The diagnosis is confirmed by culture on special media and by animal or chick embryo inoculation of blood, joint fluid, or abscess material. Specific agglutination tests may be obtained in a few laboratories where the antigen is available. The titer usually reaches a peak between 1 and 3 months and may persist for 2 years. Specific skin tests may be positive for 4 to 5 months after the infection. Six deaths have

been reported due to this organism in the United States. The most significant findings at autopsy have been myocarditis, endocarditis, and pneumonia.

The disease caused by *S. minus* is remarkably similar clinically to that caused by *S. moniliformis*. The fever is more likely to be relapsing. The local ulcer tends to be more indurated. Arthritis is less common. Approximately 51 percent have false positive serologic tests for syphilis. *S. minus* may be recognized by darkfield examination or by animal inoculation.

Either penicillin or streptomycin is usually effective in the treatment of rat-bite fever caused by either of the organisms. However, one case due to *S. moniliformis* has been reported which responded to streptomycin after failing to respond to penicillin, and another case caused by the same organism was reported which was refractory to both of these antibiotics. It is advisable to perform antibiotic sensitivity tests on the organisms.

CASE REPORT

K. S., an 8-year-old white boy, was admitted to the United States Public Health Service Hospital, Seattle, April 28, 1952, with chills, fever, headache, and vomiting of 6 hours' duration. Four days prior to admission, the child had been bitten on the tongue by his pet white rat. Other members of the family were in good health.

On physical examination his temperature was 103° F., his pulse was 96 per minute, respirations were 22 per minute, and blood pressure was 110 mm. Hg systolic and 70 mm. Hg diastolic. He did not appear to be in acute distress. There were small petechiae around the mouth. There was a small ulcer on the left side of the tip of the tongue with a small area of induration around the ulcer and on the inferior surface of the tongue. The pharynx was moderately injected. Rhonchi were present in the right lower chest. A systolic apical murmur was heard on expiration only. The murmur had the quality of a functional murmur. Physical examination was otherwise normal.

The roentgenogram of the chest at admission was negative. The day following admission the leukocyte count was 17,000 per cu. mm. with

72 percent neutrophils, 25 percent lymphocytes, 2 percent monocytes, and 1 percent basophils. The erythrocyte count was 5,400,000 per cu. mm. The hemoglobin was 14 gm. The platelet count was 83,000 per cu. mm. The hematocrit was 38 percent. The erythrocyte sedimentation rate and the urinalysis were normal. The standard Kahn test was negative. A blood culture was taken on April 29 and a sample was sent to the Seattle-King County Department of Health Laboratory, together with the history of the rat bite. This laboratory recovered the *Streptobacillus moniliformis* by culture on standard tryptose phosphate broth enriched with 20 percent aseptic fluid. After 5 days of incubation the typical fluffy ball colonies were present in the broth, and smears showed the characteristic pleomorphic organisms with filaments and beads. The organism was inoculated into four mice, all of which died, and the same organisms were recovered from them. The laboratory has been able to maintain the strain on Löffler's medium until this date. No pleuropneumonia-like (*L*₁) organisms were seen.

On April 29 the child was started on 300,000 units of procaine penicillin intramuscularly daily for 4 days. The temperature, which ranged between 102° and 104° F. on the first day, dropped to 101° F. on April 29. The following day the temperature was normal and remained so. After the first day the child slept well and had no complaints. The petechial rash around the mouth faded and the ulcer on the tongue began to heal rapidly.

The child was discharged from the hospital May 2, 1952. Since then he has been well. It was ascertained that the rat had been obtained from a pet shop in Seattle. The family gave the rat responsible for the illness to the Seattle-King County Laboratory where it was autopsied, but no organisms were obtained from the examinations.

Sanitary Quality of Crushed and Cubed Ice As Dispensed to the Consumer

By V. D. FOLTZ, M.S.

INFORMATION on the sanitary quality of ice as it is served in iced drinks and used to chill foods in public eating places apparently is unavailable in the literature. There are references in the literature of the early nineteen hundreds to studies made on "natural" ice harvested in the winter season and stored for summer use, but these reports are conflicting as to the quality of the ice. At that time it was common belief that natural freezing would destroy any disease germs that might have been present in the original water.

At the present time most of the ice used for chilling food and drink for human consumption is commercially frozen. With the introduction of the use of high-quality water in producing ice, it was generally assumed that the ice would be of the same high quality. This assumption was questioned, however, as early as 1905. A study of a typhoid epidemic in the District of Columbia in that year necessitated the examination of both the "natural" and artificial ice sold in the area, and sanitary surveys revealed that the sanitary conditions in commercial ice plants left much to be desired (1).

In recent years sanitarians have formulated standards of quality for commercial ice and have introduced regulations covering such items as (a) the water supply used, (b) the

plumbing and toilet facilities of the premises and surrounding area, and (c) the employees' health. If such regulations are adhered to, the ice (usually in 300-pound cakes) should be of high sanitary quality when pulled from the freezing tanks. As evidence that the cake ice in the area covered by the studies described in this report is of high quality, the following data are submitted. Ten samples of cake ice, representing at least five ice plants, were purchased, handled with the same aseptic precautions, and cultured in the same manner for coliform, clostridia, and standard plate count as subsequently described for crushed and cubed ice. No coliform or clostridia organisms were detected in any samples, and the average standard plate count for the 10 samples was only 6.8 per 1 ml. of water.

In a previous report attention was called to the gross inert material and high coliform, anaerobic, and total plate count of a limited number of crushed-ice samples (2). This paper reports more detailed studies of the sanitary quality of both crushed and cubed ice as it is dispensed to the consumer.

Test Methods

Standard Methods for the Examination of Water and Sewage (ninth edition) was followed in detail for all procedures relative to plate counts and tests for the presence of members of the coliform group.

The "stormy fermentation" test for the *Clostridium welchii* (*Clostridium perfringens*) group was made by inoculating sterile skim milk in test tubes covered with a paraffin-vase-

Mr. Foltz, professor and acting head, department of bacteriology, Kansas State College, and bacteriologist in charge, Kansas Agricultural Experiment Station, gave this paper before the American Public Health Association, October 21, 1952, at Cleveland, Ohio.

line seal, with 5 portions each of 10.0, 1.0, and 0.1 ml. of water, heating the tubes at 80° C. for 15 minutes, immediately chilling, and then incubating them at 35° C. for 5 days. No tube was called positive unless the seal was blown from the tube and the curd gave a typical "stormy" type of appearance.

Isolation of the dominant type of coliform was made from eosin-methylene blue agar plates streaked from the smallest inoculum giving a positive or a doubtful presumptive test. Identification was carried only to the point of determining the methyl red and Voges-Proskauer reactions on each isolate. Further studies on a limited number of samples were made by adding 50.0-ml. quantities of melted ice to 50.0 ml. of double strength selenite F enrichment medium. This mixture was incubated at 35° C. for 24 hours and subcultured onto bismuth sulfite and S S agar. Colonies suspected of being noncoliform enteric types were isolated and subjected to differential study, as outlined in *Diagnostic Procedures and Reagents* (third edition).

To detect the presence of and to identify micrococci and streptococci, incubation of 5 portions each of 10.0, 1.0, and 0.1 ml. of water in the enrichment medium designed by Ritter and Trece (3) for the isolation of cocci from swimming pool water was the first step. When growth appeared, all tubes were subcultured on 5.0 percent sheep blood agar. No tube was regarded as negative until 10 days' incubation at 35° C. revealed no growth.

From the blood agar plates incubated at 35° C. for 48 hours, colonies suspected of being micrococci and streptococci were isolated for further study and identification. Those colonies proving to be streptococci were grouped according to the methods outlined by Sherman (4). Micrococci were identified according to *Bergey's Manual* (sixth edition), and the identification was substantiated with additional tests.

Physical examination of ice samples was limited to the passage of 300 ml. of water through cotton sediment disks with an exposed surface of 0.68 sq. in. A comparison of the amount of sediment collected was made with standard sediment disk photographs, as described in *Standard Methods for the Examination of Dairy Products* (ninth edition). Sedi-

ment identification was made by wide-field binocular microscope examination.

Residual chlorine was determined colorimetrically by the orthotolidine method, using a Hellige comparator.

Field Procedure

Samples of ice were collected from hotels, restaurants, soda fountains, hospitals, and soft-drink parlors in sterile wide-mouthed jars. The filled jars were sealed immediately with a lid lined with sterile cellophane to prevent the possibility of lacquer from the jar lid flaking and confusing the sediment picture. Bagged ice was purchased and aseptically transferred to the same type of container. All samples reached the laboratory only partially melted. They were tempered at 40° C. until the ice melted and then immediately examined.

The ice samples were collected from establishments in central Kansas within an area having a radius of 150 miles. They included 77 samples of crushed ice and 37 samples of ice from automatic ice-cube machines. Ten of the ice-cube samples came from hospitals. It was thought that this latter group of samples would represent the ideal in sanitary machine care and ice-dispensing techniques. Collections of samples were made either in June, July, or August, or in December or January so that a comparison of the sanitary quality of ice during the two climatic extremes could be made.

Numbers of Bacteria

In table 1 are presented the data on the numbers of bacteria found in the 114 samples of ice included in this study. Only 27 (about 23 percent) of the 114 were free from coliform contamination and would be of acceptable quality on the basis of drinking water standards.

The 84 samples collected during June, July, and August contained the highest average MPN (most probable number) of both coliform and anaerobic bacteria and the second highest average standard plate count of the 6 groups of samples. The winter samples had a comparatively low average coliform count, indicating a decidedly better quality of ice than

Table 1. Numbers of bacteria found in 114 samples of crushed and cubed ice

Range of MPN coliform per 100 ml.	Number samples	Average MPN coliform per 100 ml.	Average MPN clostridia per 100 ml.	Average standard plate count per 1.0 ml.

1,600->1,600-----	0	0	0	0
Average-----	---	0	0	1,029

the summer samples. However, the coliform count coupled with an average MPN of 17 clostridia per 100 ml. of water and a standard plate count of 11,415 bacteria per 1 ml. indicates a poor quality product on the basis of the standards for acceptable drinking water.

Only 10 (13 percent) of the 77 samples of commercial crushed ice were found to be free of coliform bacteria, whereas 17 (46 percent) of the 37 samples of cubed ice were free of coliform organisms. All 10 of the hospital samples were free of both coliform and clostridia organisms.

Types of Organisms

The dominant coliform types isolated from the 87 samples giving positive and doubtful presumptive tests were *Escherichia coli* from 41 samples and *Aerobacter aerogenes* from 46. In some samples only one type of the coliform group appeared to be present; but in the majority of the samples a mixture was observed.

From the limited number of samples subjected to selenite F enrichment and subsequent streaking on S S and bismuth sulfite agar, a number of isolations were made from entericlike colonies. Examination of these cultures yielded organisms identified as *Proteus* spp. and *Paracolobactrum* spp.

Pseudomonas spp. were found in 25 of the 114 samples studied; *Pseudomonas aeruginosa* was isolated most frequently, followed by *Pseudomonas fragi*.

Thirty-two of the 37 machine ice-cube samples were cultured in sodium azide enrichment broth to make possible the isolation and subsequent identification of micrococci and streptococci. The results are recorded in table 2 in such a manner as to make possible a comparison between growth in azide broth and the isolation of coliform types. The frequency of micrococci and streptococci isolations from coliform-positive and coliform-negative samples is also shown.

Growth developed in sodium azide medium in 24 (75 percent) of the 32 samples cultured in this medium. From these azide-growth-positive samples coliform types were isolated from 16, streptococci from 19, and micrococci from 22. It is significant that coliform types were found in only 1 of the 8 azide-negative samples. Seventeen of the coliform-positive samples were found to contain streptococci and/or micrococci—streptococci in 14 and micrococci in 16. In contrast the 15 coliform-negative samples yielded only 6 streptococci and

Table 2. Number of samples from which isolations of micrococci, streptococci, and coliform organisms were made, and correlation of findings: 32 samples of cubed ice examined

	Azide broth		Coliform isolation	
	Growth	No growth	Positive	Negative
Micrococci isolated.....	22	-----	16	7
Micrococci not isolated..	2	-----	1	8

Streptococci not isolated..	5	-----	3	9
Coliform present.....	16	1	17	15
Coliform not present....	8	7	-----	-----
Growth in azide broth....	24	-----	16	8
No growth in azide broth..	-----	8	1	7

7 micrococci isolations. One hundred and eighty-four cultures of micrococci were isolated from the 24 growth-positive-azide samples. A brief study of the micrococci revealed that 97 were hemolytic, and 87 nonhemolytic; 11 (5 percent) were coagulase positive, and 173 coagulase negative; and 63 produced yellow, 14 orange, and 107 white pigment. The organisms were identified as belonging to the following species: *Micrococcus pyogenes* var. *aureus* and var. *albus*; *Micrococcus citreus*; *Micrococcus flavus*; *Micrococcus epidermidis*; *Micrococcus candidus*; *Sarcina flava*; *Sarcina aurantiaca*; *Sarcina lutea*.

Ninety-eight streptococci cultures were isolated from the 24 azide-positive samples. Of these cultures 87 were found to belong to the enterococcus group, 10 to the lactic group, and 1 to the viridans group. A large percentage of the cultures grouped as enterococci grew at 10° C. and at 45° C. and in the presence of 6.5 percent sodium chloride, indicating that they were probably *Streptococcus fecalis*.

The MPN of micrococci ranged from 2 to more than 1,600 per 100 ml. of water, and the streptococci, from 4.5 to more than 1,600. The micrococci gave higher MPN values than the streptococci.

Sediment

Sediment collected by filtration and examined under the wide-field binocular microscope

was found to contain sand, clay, assorted colored fibers, assorted colored threads, vegetable fibers, finger-nail-polish scales, insect fragments, rodent hairs, and wood splinters. The amount of sediment removed by the filtration of 300 ml. of water ranged from 10.5 mg. to 0.25 mg., averaging 2.25 mg. The ice-cuba samples contained the least amount of extraneous material, and the group of summer samples contained the largest amount of sediment. Available residual chlorine was consistently low or entirely absent; the largest amount in any sample was 0.01 ppm.

Discussion

The finding of only 13 percent of the crushed-ice samples to be of satisfactory sanitary quality when judged by the standards used for public water supplies indicates that most of the crushed ice in the area covered by this survey is of extremely poor quality. In general, the same conclusion applies to automatically frozen cubed ice dispensed in commercial establishments.

The frequent isolation of *E. coli*, universally accepted in water analysis as an indicator of pollution of human or animal origin, suggested the desirability of testing for other types of organisms of possible sanitary significance. The subsequent tests for clostridia, enteric bacilli, micrococci, and streptococci revealed that one or more of these four groups of bacteria, which are intimately associated with the human body, were found in the majority of ice samples. Frequently the numbers were large enough to suggest recent heavy pollution of possible human origin.

The organisms found are of sanitary significance not only because ice is introduced directly into beverages, but also because it is used in direct contact with foods, some of which are eaten raw, to accomplish chilling. Micrococci, streptococci, coliform types, paracolon organisms (5), and *Proteus* (6) all have been identified as or suspected of being the causative agent in food poisoning. *Pseudomonas* spp., which were detected in 22 percent of all ice samples examined, are known to play an important role in the spoilage of certain foods (7). Thus, crushed ice in direct contact with

food may serve as a source of contamination with both food-spoilage and food-poisoning organisms.

Origin of Microorganisms

The question naturally arises as to the origin of the large numbers of bacteria found in ice when it reaches the consumer. Time has not permitted a thorough investigation of this phase of the problem, but some information is available.

Ice is usually manufactured from a water supply which is tested regularly and maintained at an acceptable sanitary level. Furthermore, cake ice as taken from the freezing tank was found to be entirely satisfactory, whereas crushed ice from the same plant was found to be highly contaminated. Finally, the temperature within a mass of crushed ice and the limited time interval between crushing and consumption would, for practical purposes, eliminate growth of all the organisms tested for in this investigation. Thus, it would seem reasonably certain that most of the microorganisms found in crushed ice when it reaches the consumer have gained entrance at one or more points between the freezer and the consumer.

No effort was made in this study to evaluate the relative significance of factors which may contribute to the contamination of crushed ice. Even a casual examination of the average ice plant and other facilities for handling ice, however, will indicate many possible points of contamination: the ice plant itself; the sawing, crushing, and grinding equipment; the containers in which the ice is transported; the loading and unloading docks; the delivery trucks and insulating blankets; and the dispensing facilities. Factors to be considered are the construction of the ice plant, the maintenance of the equipment, the protection afforded the ice after it leaves the freezing tank, and the practices used in handling the ice.

Although the bacterial content of cake ice was found to be practically nil, the producer is not relieved of all responsibility for the quality of the crushed ice delivered to the consumer. A rapidly expanding practice in the handling of ice is for the producer to deliver crushed ice to the dispenser. The ice may actually be packaged in bags which the retailer dispenses

intact. Several samples of bagged crushed ice were included in this study, and no significant difference in quality was noted between this ice and the crushed ice collected from the individual dispensers.

The fact that ice from automatic freezers in hospitals was found to be of high sanitary quality whereas most of that from machines in retail establishments was found to be of poor quality indicates an absence of sanitary precautions in machine care and in dispensing techniques in the latter. The feasibility of producing high-quality ice with the automatic ice-cube machine is demonstrated by the finding of all hospital samples free of coliform and clostridia organisms.

Corrective Measures

Despite the fact that ice is by its very nature one of the products most amenable to sanitary production and handling, the data presented here leaves no question as to the poor sanitary quality of much of the ice dispensed to the consumer in the area covered by this survey. What are the reasons for this apparently paradoxical situation? Primarily, it is due to the absence of factual information concerning the quality of consumer ice; secondarily, to the lack of appreciation, on the part of producers and handlers, of the factors influencing the sanitary quality of ice. It is hoped that the facts presented here will stimulate such additional research as is necessary to evaluate the relative significance of the many factors contributing to the poor quality of crushed and cubed ice. Only with such information will it be possible for public health authorities to formulate adequate regulations concerning production and handling of this product.

In the meantime, any well-trained sanitarian can initiate an educational program in his community, a program which will acquaint the public with the need for a better product and provide the producer and handler with the necessary information to meet a demand for high-quality ice.

Summary

Data are submitted which show that the majority of crushed and cubed ice at the consumer level is of extremely poor sanitary quality.

Evidence is presented indicating that initially ice from both commercial and automatic freezers is of acceptable quality. The high plate counts, the presence of significant numbers of *Escherichia coli*, clostridia, micrococci, and streptococci, and the quantities and types of inanimate material present in crushed and cubed ice suggest recent, heavy contamination, at least a portion of which is of human origin. The implications associated with the extensive consumption of such a product are obvious, and the problem deserves early attention by public health authorities.

Public Health Service Staff Announcements

Dr. James R. Shaw has been assigned as chief of the Branch of Health of the Bureau of Indian Affairs where he will supervise the administration of 59 Indian Service hospitals and the public health program of the Bureau. He has been chief of the Division of Hospitals, Public Health Service, the past year. Previously, he was medical officer in charge of the Public Health Service Hospital in Detroit. Dr. Shaw has also held medical staff positions in the Public Health Service Hospital in San Francisco and its clinics in Los Angeles and San Pedro, and has served as district medical officer of the Coast Guard at Long Beach, Calif. He was admitted to the commissioned corps of the Public Health Service in 1939.

Dr. Clifton K. Himmelsbach has been appointed assistant chief of the Division of Hospitals, Public Health Service, as successor to **Dr. Myron D. Miller**, recently assigned medical officer in charge of the Public Health Service Hospital in Seattle. For the past 5 years, Dr. Himmelsbach has been medical officer in charge

of the Washington, D. C., Outpatient Clinic of the Public Health Service. He has held medical staff positions in several Public Health Service hospitals, and in the Service's hospital in Lexington, Ky., he directed clinical investigations on narcotic drugs and addiction. Before coming to Washington in 1947 as chief of the medical operations branch of the Federal Employee Health Program, he was a medical consultant for the Office of Vocational Rehabilitation.

Dr. Stanley E. Krumbiegel has been appointed medical officer in charge of the Public Health Service Outpatient Clinic at Washington, D. C., to succeed **Dr. Himmelsbach**. Dr. Krumbiegel has been medical director of the Bureau of Prisons, Department of Justice, since 1948. Since receiving his commission in the Public Health Service in 1939, he has served as medical staff officer in Public Health Service hospitals in Boston and on Ellis Island, and as staff psychiatrist and chief medical officer in a number of Federal penal and correctional institutions.

State Laws on Financing and Staffing Local Health Departments

By CLIFFORD H. GREVE, M.S.P.H., and KATHRYN J. CONNOR

This report completes a three-part presentation in Public Health Reports of a study of State laws, regulations, and practices applicable to local health departments, made by the Division of State Grants of the Public Health Service.

The first section, entitled "Provisions of State Laws Governing Local Health Departments" (January 1953, pp. 31-42), described existing laws, regulations, and accepted practices with respect to boards of health, health officers, and the organization of local health departments.

The second section is entitled "General Regulatory Powers and Duties of State and Local Health Authorities" (April 1953, pp. 434-438).

A separate 68-page report entitled "State Laws

Governing Local Health Departments" (PHS Publication No. 299) presents in tabular form data by individual States on all aspects of the study.

Thus, a comprehensive report of public health legislation is available as reference material to guide States in planning legislative programs in this field.

The data summarized in these reports are from questionnaires prepared by regional office personnel of the Public Health Service assisted by regional attorneys of the Department of Health, Education, and Welfare. Information relating to procedures carried out by practice in the absence of statute or regulation was collected in personal interviews with State health officers or members of their staffs.

• • •

STATES have fewer laws, regulations, and practices pertaining to the financing and staffing of local health departments than they have for governing the appointment and qualifications of local health officers, the establishment of local health units, or the delegation of broad regulatory powers and duties to State and local health authorities.

Distribution of Costs

In all States, local units of government are

Mr. Greve is chief and Mrs. Connor is an analytical statistician of the analysis and reports section of the Division of State Grants, Bureau of State Services, Public Health Service.

permitted to raise local revenues to finance all or part of the cost of local health departments. However, specific or general limitations are frequently placed on this general power either by statute, regulation, or by practice without statutory authority. Some of the limitations may be applicable only to some types of local governmental areas or only under certain conditions.

About two-thirds of the States prescribe methods for allocating the cost of operating local health departments among participating local units of government. Such allocation may involve distribution of costs among counties in district health units, or between county and city in city-county units, or among townships in single-county units. Specific methods for the proportionate distribution of costs

among local governmental units are established by statute in 26 States, but in 6 of these the method of allocation is applicable only to district health units, and in one other State only to cities and districts. In describing the method of apportionment of funds from local resources among local units of government, States most frequently report the use of a population factor.

Local Financing

Several types of provisions are used by the States to determine the share of total local health department costs which are to be met from local revenues. Eleven States require that a prescribed percentage of the cost of operating each local health department be met from local revenues (table 1).

Local financing of health departments is frequently influenced by statutory tax provisions. Local taxation is based primarily upon real estate valuations. Tax limit provisions in 21 States establish by law a specific millage limitation applicable either to specific taxes for public health purposes or to taxes in general. In either case such provisions place a limit upon local revenues available for public health purposes. Twenty-three States have statutes which permit levy of a specific health tax in excess of other tax millage limitations. In only 4 States does the law require the imposition of a mandatory tax rate or millage for the financing of local public health programs.

Four States require a local per capita appro-

priation as the share to be borne by local revenues. In 4 States a minimum dollar amount is required of local governments in financial support of the local health department.

Twenty-eight States report other provisions that are applicable to the financial support of local health departments. These are generally contained in statutes but are usually limited in their application. Frequently, a State may have more than one provision applicable to the local financing of health departments.

Nineteen State health officers indicated that local health departments should be supported from the general tax fund, while 21 State health officers thought local financial support should come from special tax provisions. At least 7 health officers thought local financial support should come from both sources.

State Financing

Inadequate local revenue from tax resources requires local health units to depend in part upon State funds and other resources for assistance in financing their health programs. Nearly three-fourths of the States have statutes which authorize the distribution of State funds to local health units (table 2).

Methods used to distribute State funds are important in the sharing of State revenue with local units of government. These methods usually fall into two groups: those designed to allocate available funds by some objective method, and those based on subjective judgment. Objective formulas vary widely between

States but, in general, are designed to provide a State-local fiscal relationship which offers security to local health programs. Comments made by State health officers indicate that most of them think it desirable to establish a relationship between local and State funds for allocating the cost of local health units.

One type of objective formula used by one-fourth of the States provides that a percentage of total operating costs of local health units be met from State funds. By a second method of distribution closely related to that of paying a percentage of the total cost, the State pays a percentage of the salaries of all or certain selected employees of local health departments.

Other types of objective formulas are used by 17 States in the distribution of State funds. There was wide variation in the objective methods described, but the use of factors of population and financial need was reported most frequently. Basic grants to each local area, or grants based upon specific health needs, are not uncommon factors employed. As an adjunct to the distribution of State funds, contracts are frequently drawn between State and local officials to legalize the financial agreement made either through the use of subjective judgment or an objective formula.

Payment Procedures

The designation of an official custodian of local health funds is accomplished by law in

33 States, in 8 additional States by common practice, and in 1 State by regulation. Almost universally, the person designated as official custodian of the local health unit funds also disburses the funds. In districts, the treasurer located in the most populous county or in the county housing the headquarters of the local health department is generally the disbursing officer for multicounty units.

The payment of State funds to local health units is made on a reimbursable basis in only 20 States. Six of these States have statutes providing for a reimbursable payment procedure; 13 States do so by practice, and 1 State by regulation.

Actually, the reimbursable principle is frequently achieved by issuing State checks to cover salaries of local health department employees. Thirteen States report that they issue checks against local funds covering salaries of local health department employees, but in only 3 States is this done on the basis of a statutory provision.

Twenty-six States issue State checks to pay the salaries of local health department employees who are paid from State and Federal funds. In conjunction with this procedure, the use of State or Federal funds in local health department budgets is frequently limited to salary items. In 1 State it applies only to the salaries of nurses employed in local health units. In only 13 of the States which pay local employees with State checks does the check indi-

cate the source of funds from which the employee is being paid.

Ten States require that local funds for the support of local health units be deposited in State treasuries for disbursement. Three States require local funds to be deposited locally for disbursement by a State health department official or other State disbursing officer.

State funds are paid to local custodians of funds for disbursement in 21 States. Only 8 States have statutes establishing this procedure, and in 1 State new enabling legislation sets up the procedure. The payment of State funds to local custodians is specifically prohibited by law in 2 States.

Budgets and Plans

The responsibility for the preparation of local health department budgets is delegated to a wide variety of officials, and such delegation is more frequently based on practice than on

statutory provision. In 14 States, local health department budgets for single governmental units such as cities or counties are prepared by the State health department. Local health officers serving this type of unit have some responsibility for the preparation of budgets in 30 States (table 3).

In 10 States district health department budgets are prepared by the State health officers although only 1 State has statutory provisions prescribing this procedure. District health officers prepare their budgets in 14 States, while district boards of health prepare the budgets in 19 States.

After budgets of local health departments have been prepared, there is usually some procedure established for their approval. Provisions for budgetary approval are more frequently established by practice than by statute and may involve more than a single official or agency. The State health officer is responsible for approving local health department budgets in 30 States, and he also has authority in 30

States to approve district health department budgets.

As indicated in table 3, the local board of health is responsible for approving budgets for single governmental units in about half the States. In 33 States the local legislative body has some responsibility for approving budgets. Local administrative officials have responsibility for the approval of budgets in 12 States.

In district health units the budgets are usually approved by the State health officer, but district boards of health have powers of budget approval in 15 States. Local legislative bodies in districts may approve budgets in 21 States.

Almost universally, State health officers commented that local health officers should prepare the budgets with some other local or State authority, or both, having power of approval.

A relatively new procedure of plan preparation requires local authorities to outline their health programs in advance. Less than half of the States have provisions for the preparation of plans either through statutory requirements or in practice. Seventeen States indicated that plans for single governmental health units are prepared in practice.

Twelve States require plans from district health units in practice, while 5 other States have statutory requirements with respect to plans for these units.

The majority of States which require plans from local health units also require that more than one authority approve each plan, and this approval is usually based on practice rather than on regulation or statute. The State health officer is the authority most frequently assigned this responsibility, but in only about a third of the States requiring his approval is it based upon statute.

Staffing Local Health Departments

Staff appointments in local health units usually are made by the local health officer or the local board of health. Frequently, there is joint approval by the local health officer and local board of health in making such appointments. The law in some States requires that certain officials, such as the city and county commissioners, or the State health department be consulted with respect to staff appointments. Thirty-seven States have provisions permitting the local health officer to make staff assignments to local units (table 4). In 20 States the local board of health has statutory appointing authority, but in a dozen States these boards are not the sole possessors of this authority. In 4 States the law limits the appointing authority of local boards of health to city health departments. The questionnaires

³ Authorized by regulation in 2 States.

further reveal that 10 State health departments make staff appointments to local health units.

Predominantly, the responsibility for staff appointments to district health units rests with the district health officer, and in 20 States he has such authority by statute (table 4). The data also indicate that statutes in 14 States provide district boards of health with the responsibility for making staff appointments, but in only 6 States do they perform this duty alone. The State health department appoints personnel to district health units in 8 States. Statutes in 3 States require that appointments to multi-county health units be made by each constituent unit making up a district health department.

In 17 States personnel in district health units serve only the constituent governmental unit to which they are assigned rather than serve throughout the district. This is a statutory requirement in 5 States. Personnel serving in district health units are responsible to the district health officer in 37 States.

Merit System

Personnel of local health departments in the majority of States are employed under some type of merit system. One-third of the States have statutory provisions for a merit system covering local health department employees. Regulations for the establishment of a merit system for local health department personnel exist in 7 States; however, in 2 of these States statutory provisions for this purpose also have been enacted. Several States indicate that a merit system is operated for local areas only if they receive State aid.

In the questionnaires States were requested to specify the type of merit system applicable to their local health department employees. A total of 31 States indicated that the State merit system was extended to cover local employees. In 14 States this was accomplished by statute. In 10 States such a procedure was carried out in practice and in 7 States by regulation. Four States administer a separate merit system for local health unit employees, but these are operated either on the basis of practice or by regulation.

Seven States have statutes providing for a locally administered merit system, but in 6 of

these States such provisions are limited in their application. Nine States provide for locally administered merit systems by practice with more than half of these having limited application. In one State regulations provide for a locally administered merit system of limited application.

There are 11 States in which local health department employees are, either by practice or by regulation, State employees and therefore employed under the merit system applicable to State employees.

Compensation Plans and Retirement Systems

More than two-thirds of the States have statutory provisions for a statewide compensation plan applicable to local health department employees. In addition, all except one of the remaining States have compensation plans established by regulation or by practice. It should be pointed out, however, that only 5 States indicated that the statewide compensation plan provided for differences in various sections of the State.

There is wide variation between States in the authority named to establish compensation plans. By statutory provision in 22 States the local boards of health establish such plans. A few States name the local health officer, the State health officer, or the State board of health as the establishing authority although few reported this as a statutory provision. In one-third of the States the law requires some other authority, such as the State personnel board or city or county commissioners, to establish the compensation plan.

Placing of local health unit employees under a retirement system is authorized by law in 33 States. Not all local health unit personnel in the same States are covered by the same retirement system. The laws in many States provide for an extension of State retirement plans or the purchase of social security benefits, or both. Local health employees infrequently come under a locally administered retirement plan.

Summary

Local governments in all States are permitted to raise revenue from local resources for the

support of local public health services, but insufficient local revenue necessitates the allocation of State funds to carry on local public health programs. In this connection, States frequently distribute their funds by some subjective formula rather than according to an objective formula. This report shows that requirements for financing local health units are most frequently carried out by statutory provisions. On the other hand, the establishment of payment procedures and planning activities, such as the preparation and approval of local health unit plans and budgets, is usually done by accepted practice.

Payment procedures usually provide for the designation of an official custodian of local health funds, and he is usually the person who distributes the money. Although State funds are often paid on a reimbursable basis, few States follow this procedure by law. More than half the States permit the issuance of State checks to pay local employees.

Statutory provisions generally govern the appointments of personnel to local health unit staffs. These appointments are usually made

by one or more authorities but are frequently the responsibility of the local or district health officer and the local or district board of health. The State health departments seldom have the responsibility for assigning local personnel. It is the law in several States that the county or city commissioners, the board of supervisors, or the governing legislative body make local staff appointments.

Although the majority of States report that local health unit personnel are covered by some type of merit system, this coverage rarely is based on statute. Statewide compensation plans, which have been adopted in all but one State, usually are established by local boards of health according to law. The law in two-thirds of the States requires that local health unit employees be placed under a retirement system. Essentially the same number of States report the extension of State retirement plans as report the purchase of social security benefits for local health employees. A few States report the existence of both systems, while some States provide for a locally administered retirement plan.

A Date Book Invitation

RHODE ISLAND. A regular attendance of 75 was attracted to a 1952-53 series of nurses' conferences in Providence by an effective date book device. Since 1950, the bureau of public health nursing in the State health department has worked to develop ways of getting the public health aspects of nursing included in the basic nursing curriculum. The

date book was another step in this direction.

The booklet was prepared by the bureau, and the series was sponsored by the bureau and by the State nursing league. Meetings were free and were held monthly in Providence hospitals.

The booklet was sent to social workers, faculty members of schools of nursing, and others who teach basic nursing students. Titled "We Need Rhode Island's Social and Health Agencies—And They Need Us," it announced that the conferences were designed to acquaint members with the health and social resources available in Providence. For each meeting, the subject, the

time, and the place were listed on a separate page. Small (about 6¼" by 4¼"), inexpensive (mimeographed), the date book also contained title and introduction pages.

Speakers represented such agencies as the State cancer and heart societies, the Providence police, school, and social welfare departments, and the University of Rhode Island. Typical subjects included discussions on community resources for treating drug, alcohol, and mental health problems; on the availability of child welfare services and rehabilitation for the handicapped; on industrial participation in maintaining community health; and on the success achieved by interagency cooperation.

Unfinished Business and New Forces In Environmental Health Orthodoxy

By ABEL WOLMAN, Dr.Eng.

ON EXAMINING the table of contents of a forthcoming volume on public health under the editorship of one of the most distinguished workers in that field, I was astonished to find no mention of environmental sanitation or hygiene. The volume comprehensively covers elements in the public health field which are largely medical, dealing with the newer fields such as hospital care and geriatrics. But the book ignores the environment.

This field has been well defined by Winslow as "environmental therapeutics," the term encompassing those controls of the environment and that machinery of the community which go into the preservation of health and the prevention of disease.

Perhaps it might be useful to probe a bit into some of our current assumptions and practices in light of Winslow's farsighted concept. Also, we might attempt a glance forward.

Orthodox Functions

Begin with a look at what current engineering literature describes as the "orthodox functions" of the sanitary engineer. I want to take issue with this term and to explain why.

Dr. Wolman is professor of sanitary engineering at the Johns Hopkins University. Awarded the Sedgwick Memorial Medal "for distinguished service in public health" in 1948 by the American Public Health Association, of which he was president in 1939, his professional experience has spanned nearly a half-century and his assignments and interests have taken him into a wide variety of fields.

The orthodox functions are so familiar that nobody in a country such as this worries about water supply so long as something that is reasonably liquid and reasonably clear flows out of the spigot. We have become accustomed over a quarter of a century to a status in which that is the expected.

The canvass of the functions of the State, municipal, and county health departments made by the American Public Health Association recently bears out the fact that the so-called orthodox functions—such as water supply, sewerage, refuse disposal, and food sanitation—take a declining portion of sanitary engineering staff time in those agencies.

Yet travel about the country reveals that although those problems are by definition orthodox, they are, in addition, unsolved. They are unsolved technically and unsolved from the more important standpoint of coverage of the population. Many millions of persons living in well-defined communities in this country—the sparsely populated areas not included—have neither a public water supply nor public sewerage facilities. We are confronted with a persisting problem which has been accepted as solved partly because typhoid fever, the earlier measure of the problem, is disappearing.

In appearing yearly before the Maryland Legislature, in my early days, I defended the State health department budget exclusively and simply on the typhoid fever death rate decline. The familiar curve of typhoid fever disappearance was impressive, quantitative, logical, and simple. It was a much happier day than now

Before the regular monthly general staff meeting of the Public Health Service in Washington on May 1, 1953, an internationally known teacher and practitioner of sanitary science informally examined that field of public health endeavor which Dr. Winslow has characterized as "environmental therapeutics." In the following condensation of Dr. Wolman's informal remarks he notes that while many of our currently underemphasized problems are "by definition orthodox, they are in addition, unsolved." In closing, Dr. Wolman remarked that he knew he was speaking dogmatically and that he had "purposely chosen areas of criticism, simply on the assumption that you know what you have done."

when less dramatic and more subtle complexes must be explained in support of a budget.

Typhoid days are gone, and now people ask: "Why should you concern yourself with the extension of water supply? The typhoid fever rate total is quite small throughout most parts of the United States."

The combination of that disappearing index of necessity (or accomplishment) and the fact that we are dealing with orthodox and familiar principles has resulted in an important technologic and administrative gap in the matter of water supply and sewage and refuse disposal.

Progress in Sewage Disposal?

It required nearly a third of a century to eliminate cesspools and septic tanks in a large part of the congested areas of the United States. Today, we find that accomplishment has become negative. In the last 12 years we have put in more septic tanks and cesspools than we took out in the previous 40. We describe that situation as one which "crept up" on us.

Most health officers and sanitary engineers can recall the struggles to eliminate those early devices from the metropolitan areas. Recently a report came from one State of the installation of thousands of septic tanks and derivatives thereof in the past 5 years—perhaps half of them in areas in which the ground water is 8 inches or so below the surface.

The careful distribution of sewage among the population in certain congested areas has been eminently successful! We could not have done it better by design.

Community Management Problems

All of us in public health and public administration have fallen down in two areas of effort. We have failed to develop the administrative and fiscal machinery necessary to provide the public amenities of water supply, sewerage, and sewage disposal in areas outside the political boundaries of individual cities. Efficient planning, with very few exceptions, declines as one moves out of the municipality itself into its metropolitan areas, and in turn from the metropolitan areas into the more rural counties. It virtually disappears on an intercounty basis. Here we encounter the absence of either or both a responsible official agent or a militant public interest and knowledge. The two, of course, are inseparable, whether in city, metropolitan area, or county.

In the city, the problem is lifting the sights: first, of municipal officials, a task made more difficult because of historical limits; and second, of individuals, who do not see that city plans and ordinances do not necessarily whittle away their private rights.

As in epidemics, government takes action when the hazard to the many becomes too great. It has been about 18 years since the zoning ordinance of Baltimore was upheld by our court of appeals on the basis that smoke and carbon dioxide and congestion were true public health hazards. Within the city, however, there is still insufficient integration of planning and programs by the department of public works, the department of health, the department of highways, the city planning commission, the housing

authorities, and the redevelopment commissions. And I know of no city which has been able to accomplish this integration satisfactorily.

Metropolitan and Rural Areas

In the metropolitan area and counties, we are confronted with the problem of ex parte units. As chairman of the Maryland State Planning Commission for 10 years, I called officials together from the various areas frequently but found that a political boundary line on a map is an amazing brick wall.

We are edging into progress in the direction that all would like to see. In many instances, the State sanitary engineer has the opportunity to effect cooperation because he gets around. He has a comprehensive view. His facilities in general transcend political boundaries. He has a potential—one which he has not always used because he is busy with other things and gives integration and cooperative planning a low priority.

Integration ought to have a high priority. Possibly no one would require a sanitary engineer to be also a city planner, but he could be one of the best and sometimes is.

Suburbia Needs Sewers

The tremendous growth in this country in the past decade will probably continue in the next decade, particularly in the metropolitan areas, and generally there is no organization to assure installation of conventional sanitation features. All down the line our official groups for one reason or another have failed to introduce or develop the planning that would have prevented retrogression in this area.

In some of our States, sanitary district operations are almost at a minimum. Even in one of our greatest metropolitan areas in 1950, there were 50,000 septic tanks and cesspools within the city limits. Most were brand new. Most were bad. Many were recently installed in unsuitable soils. They were the result of a city policy which decreed that sanitary sewers would not be constructed unless storm sewers were first installed. It drove those areas into a medieval system of sewage disposal. I fail to see any logic in this.

The absence of workable administrative and planning machinery in and around our cities is one charge against our past practice and one which I hope will stimulate thought and future action.

Fiscal Blind Spots

Medical officers and sanitary engineers in their fields of application have a benign disregard for how the money is found. Their objective is to get the orthodox facilities introduced.

It is astonishing to find in no few instances that, when the pressure for installation of a system begins to mount, there is no realization of the amount of money involved. There appears, sometimes, what seems almost a cavalier disregard of whether the system costs \$10, \$20, or \$30 million.

I do not take exception to that too strongly, because if systems are needed and there are sound public health justifications for them, the money should be found. However, increasing attention should be paid to devices for finding such money—and there are devices.

Research in, and transmission of, information concerning methods of finances are as desirable and necessary as is the purely technologic delineation of the system.

Housing: Gap in the Orthodox

Administration sometimes has taken an easy route which reminds me of King Canute. Since sanitary facilities are not easily available, since the administrative machinery is not easily developed, and since the money does not seem to be in sight, the order goes out that no further construction of housing can take place in a particular area.

We must find some alternative to that negativism.

One of our most distinguished sanitary district engineers has announced that the function of his particular agency is to see to it that houses in subdivisions of 500, 1,000, or more shall not be placed where the agency considers them to be inappropriate on a zoning basis. The agency has no zoning powers, but it can extend water and sewer lines. It simply says, "Out in this

area, we do not think you belong. Therefore, you cannot get our facilities." The courts have yet to speak.

Technologic Challenges

An important technologic challenge confronts us in the orthodox areas. It is reflected partly in what I have said about money.

We are using, in the fields of water supply, sewage and refuse disposal, and in housing, approximately the same structural devices, the same technologic procedures that were employed a half century ago. We have made adjustments, of course. We have a different filter bottom than the one used in 1829 in London. It is not materially different, but it is a little different. We use a type of rake, with very modest modifications, which was used in 1913.

Is the state of our art so far advanced that there can be no contributions, not only to reducing cost, but—even to a considerable extent—to modifying and improving the processes?

If you look through our sanitation and engineering rules and our designs, you find that we are the victims of uniformity. Uniformity has great administrative advantages, but it also has great administrative danger, particularly if it curbs investigation, inquiry, and critical diagnosis.

Now let's discuss the future—not 1980, but the future of tomorrow morning. There are a few happenings which have encroached upon the environmental control area and to which we are not giving—in research, administration, or finance—the attention we should.

The Chemical Environment

The first of these happenings is the tremendous advance in the chemical industry. This area of unparalleled expansion is of interest not only because it has increased tenfold in the past 25 years, but also because it deals in a field in which neither the producer, the user, nor the engineer has detailed, accurate knowledge of what is being produced in the way of wastes. It is a strange situation.

Our chemical problems of 25 years ago had elementary simplicity compared with those found in the Kanawha River or the other

branches of the Ohio, and even in such streams as the Columbia. The kind of scientific information we need is lacking. We do not even have the instrumentation for identification or measurement.

There is also a tremendous technologic challenge in determining the peripheral effects on those who use this increasingly massive chemical production.

What is the effect of the great array of materials that are placed on the market and sold through radio, television, and newspaper advertisements? What are the products that everybody uses? What is in them? What effects do they have on people? How do we know? Are those effects subtle? Are they long term? Have we any measures for them?

Ionizing Radiation

A second happening is in the field of radiation. About 6 years ago the field was challenging, but it seemed circumscribed, geographically, in total production and in numbers of facilities. Only a handful of locations and installations had been developed, though it is true that they were big, as we thought of them then.

On a map of the production facilities in the field of nuclear fission today, there is hardly a spot in the United States which has not been used for developmental purposes. An additional characteristic of the nuclear energy industry is that, unlike most others, it has gone into areas which normally we would have said would always be isolated.

Radiation is a subject which many if not most health officers and sanitary engineers have avoided. Partly this avoidance is due to the mystery of the scientific practices, partly to the mystery of the terms, and obviously to the mystery of the effects.

This is another area of environmental problems that puts us back in the period between 1800 and 1880 in this respect: We attempt to control a situation without the guidance of the microbiologist. The heavy chemical industry and the radiation industry lack microbiological and physiological criteria. Even when we can determine the extent of contamination, we cannot predict with certainty the physiological effects. The situation is reminiscent of the days

when we began to filter water without knowing why we filtered it, except that people did not like what they were getting. Today, people do not even know what they are getting or where it is coming from.

There must be in the local, State, and Federal agencies that degree of imagination and foresight that would bring more satisfactory indexes for measurement and control. The engineers are not too patiently sitting around waiting for the answers which have come from bench and field investigations, with epidemiological findings as primary guides.

The Virus Diseases

Recently, one of the distinguished workers in the field of poliomyelitis chatted about its impact upon our public health problems and controls. He said: "There may come the day—and it may not be very far ahead—when we will have in this country one of the largest poliomyelitis epidemics of a waterborne nature that the world has ever seen. Everything that I know and have done and have found in our laboratories and in the laboratories of others about its probable epidemiology leads me to the feeling that if our guard is down, and down for even a very short interval of time, with our present sensitive population which we did not have a quarter of a century ago, we will get a disaster."

Another investigator commented with respect to infectious hepatitis: "I don't know what the route of this particular virus will be in its impact on the American population. I do know this: It will be one that should be protected by environmental sanitation. Of that I have little doubt."

Most observers are convinced that part of the control of these viruses is an environmental sanitation problem. It is a problem of food and water. It is curious to have these viruses come into the environmental sphere of interest because they are, strangely enough, in water, the field of our orthodoxy. And we have taken our sights off the field of water supply.

We shall be pushed into a revived interest in water control—and I dislike to admit that the only thing that will push us back into that emphasis in every health department is a calamity. If you look over public health history, and par-

ticularly environmental sanitation history, there are periodic reminders, by epidemic, of where we fail.

When we thought we had done everything we could do with the control of milk, we had the Montreal epidemic. A modest mistake, an interesting shift in a valve, and there were 4,000 cases of typhoid fever. On the European scene, particularly in the German area, large numbers of typhoid fever cases of a waterborne origin are occurring in populations which apparently for many years had believed that the water controls were supreme, accurate, and, therefore, could be forgotten.

Again we must turn to research. Quite recently a laboratory technique—cultivation of the Brunhilde virus in the brain of mice—has been developed which may make virus studies many times more practicable than they were in 1952. We seem to be mastering identification and growth of the virus on a simpler, cheaper, and more rapid basis. We may have to wait awhile longer. But now that the technique is available, we ought to sail into detailed developmental studies.

What do our orthodox water and sewage treatments do to the viruses? How do they behave? A year ago such exploration would have taken the whole Federal environmental research budget. Chimpanzees alone would have required a large part, but there is indication that with tissue cultures and mice the answers can be searched for with greater skill, economy, and speed.

Other Environmental Problems

In this country we thought we were rid of the insect and rodent vectors until the 1952 reminder—the human encephalitis outbreak in the Central Valley of California and one of the largest in recent history.

An engineer has to look 30, 40, or 50 years hence in most of his developments, so that I risk the prophesy that we will have repetitions of insect- and rodent-vectored diseases in this country.

Morbidity and mortality statistics reflect conditions which challenge the engineer. I look at the poliomyelitis record, dramatic as it is; I

look at the typhoid record, low as it is; I look even at the respiratory diseases, the sclerotic diseases, and so on, and I find the accident total rate outstrips them all.

Home, highway, and industrial accidents are a leading challenge to public health engineers. And our health departments, not by fiat, not even by conscious agreement, 30 years ago seemed to have ruled accident prevention out of their obligation. I am glad to see that there are evidences that they are going to rule it in again. Why is it all right to kill a child in the house by a defect in structural arrangement or to kill the child on the public street by an engine, but it is not all right to kill it by a virus?

The latter challenge we have accepted in full. About the former, we still have some hesitation. I predict we will have to take it; the public demands we should.

Water for Washing

In Korea last year, a medical investigator of epidemic hemorrhagic fever said to me: "You know, from the standpoint of environmental sanitation, I would say one of our biggest deficiencies up here, and maybe one that would have reduced our mortality and sickness tremendously, is not what you people are always talking about in the sanitary field, namely, the quality of water. The thing that impresses me most is importance of the minimum quantity of water—quantity per se—which insures the capacity to be clean. One of the great demonstrations to me on the front, with all of our diseases, is that quantity of water as a disease deterrent has been ignored."

This is an interesting point of view which I confess I have never thought of before be-

cause we live with an abundance of water—not for drinking only, but for all of its multiple sanitary uses. When you get into periods or areas of shortage and stress, the mere ability to wash has a tremendous public health significance.

"I don't even care," this same investigator said, "If they wash in a polluted stream—if only they can wash."

Physiological Engineering

Much of what I have described awaits developments in collateral fields. I now wish to note an engineering field which is subtle and remote.

As we become better acquainted with the physiologist, he says: "Why is it that the engineer stays away from the piping system of the human being? Why does he feel that all hydraulics are restricted to cast iron pipe? Why doesn't he interest himself in the mechanisms of viscosity, of deposition, of corrosion, and the like in arteries?"

The physiologist asks for participation. He says: "Why don't you interest yourself in the filtration system of the kidney? We read your material on filtration through sand. We have a system of capillary filtration which outstrips almost anything you know. We would like some light on hydraulics. Why do you deal with pumps if they are made of metal, but you don't interest yourself in the umbilical cord, which is one of the finest and most interesting and baffling pumps that we know of?"

This is jumping, maybe, into 1955 or 1960, but we should be whetting the interest of promising young engineers in the field of physiological mechanisms.

The Public Health Laboratory

—Yesterday, Today, and Tomorrow—

By ALBERT V. HARDY, M.D., Dr.P.H.

THE SUBJECT upon which I have been asked to speak is timely for me since this is the 50th anniversary of the opening of Florida's public health laboratory. At such a time one is stimulated to look to the past, is at liberty to critically examine the present, and may be at ease in suggesting desirable or possible trends for the future. The history, present activities, and outlook of the various State public health laboratories, though differing in some aspects, still have many features in common. Due to my familiarity with it, Florida's experience will be used as illustrative of the past and present and as a point of departure in considering the future.

The nature of the work of Florida's public health laboratory as it has developed in the past five decades is shown in broad outline in table 1. The rapidity of growth is striking. From 996 specimens in 1903, there was an increase to 15,949 in 1910. The requests for service quadrupled in the next decade, trebled in the twenties and in the thirties, and doubled in the forties. At first the laboratory must have been used almost exclusively to aid in the diagnosis of

clinical cases, since prior to 1910 from one-quarter to more than one-half of the specimens were positive in the test requested. At present there is an active concern with the detection of carriers and with case finding, and many specimens sent in for examination come from healthy individuals. Even with exacting techniques the current proportion of positive findings is low. Having grown in an era of development and change, the public health laboratory manifests these characteristics of the age.

The Change in Emphasis

The laboratory experience with malaria, diphtheria, and typhoid in Florida is shown first in table 1 by the number of specimens examined and then is further related to available morbidity and mortality data in table 2.

At the beginning of the twenties, when there were 1,865 reported malaria cases and 352 deaths due to malaria, there were 6,537 examinations for this disease in the Florida State public health laboratories. This was an average of 4 examinations per reported case and 19 per reported death. Malaria declined in the years following, but the number of laboratory examinations increased, reaching its peak in the early forties. In the latter half of the past decade, the incidence of malaria fell rapidly while the number of requests for laboratory tests for the disease decreased slowly. In 1950, there were 351 laboratory examinations per reported case of malaria and 614 per reported death. It was then necessary to call to the attention of physicians the rarity of positive findings for malaria and to urge a

Dr. Hardy has been the director of laboratories, Florida State Board of Health, since 1946. His review of public health laboratory services was presented to the laboratory section of the Southern Branch of the American Public Health Association at its annual meeting in Atlanta, April 23, 1953. It was one of a series of papers arranged by the chairmen of the respective sections, each dealing with one phase of the general subject "Public Health, Yesterday, Today, and Tomorrow."

¹ Data for 1920 not available. ² Widal. ³ Serology. ⁴ Smears. ⁵ Positive for *Salmonella typhosa*. ⁶ New activity. ⁷ Data not available. ⁸ Predominantly clinical laboratory examinations. ⁹ Rh tests entirely. ¹⁰ In part an estimate based on the number of examinations reported.

discontinuation of a relatively routine submission of specimens for malaria examination in undiagnosed febrile illnesses.

When malaria was common, an erroneous positive finding would have had minor public health and little clinical significance. Now, one of our problems in malaria is the occasional apparently unfounded positive report offered by clinical laboratories. In earlier years, it was acceptable for competent technicians in the clinical or public health laboratory to examine malaria slides. Now, accuracy of the highest degree must be attained, and this requires the participation of qualified parasitologists.

There has been a similar experience with diphtheria. The laboratory activity in this disease increased from 4 examinations per case and 55 per death in 1910 to a peak of 88 examinations per case and 725 per death in 1940. Thereafter the requests for examination fell more rapidly than the incidence of the disease.

The individual test is better at present so fewer examinations may be adequate, but perhaps there is undue complacency and insufficient activity. The volume of work in typhoid increased even more markedly (tables 1 and 2). Thus the trend in laboratory examinations in these three communicable diseases has been an increasing number of specimens with a decreasing proportion of positive findings. As the incidence of the infections fell to low levels there was a slow decline in examinations requested, a large number of examinations per reported case or death, and a much lower proportion of positive findings, but each laboratory test and particularly each positive finding now has increasing significance, and reliability of the highest order is required.

Better Diagnostic Tests

By comparison, consider Florida's present position in examinations for tuberculosis and

syphilis (table 1). The laboratory is still in the phase of trying to provide adequate diagnostic and case-finding services. The percentage of positive findings remains high.

The objective in tuberculosis is to detect the infection prior to the onset of clinical symptoms. The mass X-ray surveys and routine radiological examinations of all patients admitted to some hospitals point to individuals warranting study, but it is the responsibility of the laboratory to ascertain whether the suspicious radiological shadow is caused by *Mycobacterium tuberculosis*. Much more sensitive bacteriological tests than those available in the past or at present are needed, and the best available present procedures must be applied by highly qualified workers. Laboratory work in tuberculosis is at its beginning, not nearing its end.

In syphilis, the laboratory has even broader responsibilities since it must provide both the screening and the diagnostic tests. Considering their nonspecific nature, the standard serologic procedures have proved surprisingly effective. These simple examinations undoubtedly still need to be used freely in Florida. Standard serologic tests for syphilis are satisfactory as screening tests, but they have serious limitations as diagnostic laboratory examinations. A more highly specific test is needed. The *Treponema pallidum* immobilization test probably represents an early step to this end. If an obvious need is to be met, State laboratories in the future must make available both a simple screening test and a more highly specific diagnostic test for syphilis. The latter

will be more costly, will increase the volume of work, and will require unusually competent professional workers, but it is one of the many challenging tasks ahead.

There is no basis for pride in the record of attainments in the laboratory diagnosis of gonorrhea. Treatment for gonorrhea is simple at present. The laboratory procedures, however, are difficult and their reliability is uncertain. For these reasons there has been a tendency to omit diagnostic laboratory tests, and serious consequences are evident. Nonspecific urethritis is being diagnosed in epidemic proportions, but such a diagnosis signifies only that the case was not proved to be a neisserian infection. Here is a bacteriological problem. Gonorrhea and similar conditions appear to need more, not less, attention.

There will be no disagreement in public health history as to the past prevalence and significance of parasitic infections in the Southern States. Hookworm disease in the early part of the 20th century was a serious cause of morbidity. Many parasitological examinations have been done in the past and in Florida this work continues to increase. There will be differences of opinion as to the present importance of this activity. Optimum health, not the mere absence of obvious illness, is the objective of public health and obstacles to the attainment of this goal must be removed. The individual has a right to be free of parasites. This may be attained by sanitation, a slow but a permanent solution. The rapid and still needed approach is through laboratory diagnosis and treatment. There is unfinished business here.

Table 2. Number of reported cases and deaths from malaria, diphtheria, and typhoid in Florida, and number of laboratory examinations per reported case and death, by year

Year	Reported cases			Examinations per case			Reported deaths			Examinations per death		
	Malaria	Diphtheria	Typhoid ¹	Malaria	Diphtheria	Typhoid ¹	Malaria	Diphtheria	Typhoid ¹	Malaria	Diphtheria	Typhoid ¹

1950.....	7	97	30	351	46	334	4	8	1	614	555	10,036

¹ Withd. * No data on reported cases and deaths. ² Cases and deaths for 1920; laboratory examinations for 1921.

Except in diphtheria the relative newness of bacteriological culture diagnosis, as is evident in table 1, is surprising. Enteric and gonorrhea cultures have been used chiefly in the past decade; those for tuberculosis, in the past half decade. Miscellaneous bacteriological service is a recent and relatively undeveloped addition to public health laboratory work in this area. To illustrate opportunities, for example, otitis externa is a widely prevalent and troublesome disorder common in summer months in the South. Physicians commonly call this entity "otomycosis" but recent studies have indicated that this is a bacterial rather than a mycotic infection. The modes of treatment are being radically changed as a result of bacteriological studies. Rightly or wrongly, swimming and the quality of water in pools and at our beaches are under suspicion. Here is but one of many neglected bacteriological diagnostic fields which warrant attention.

With the growth of veterinary public health has come the need to provide laboratory service for our public health veterinarians. The development of this work in Florida in the past 3 years has proved most interesting. The bacteriological diagnostic work in anthrax was new to us. Leptospirosis in cattle and dogs has come to the fore. There have been tests for a wide variety of poultry infections. Bacteriological studies of edible meats and in abattoirs have been revealing. Lacking a veterinary diagnostic laboratory in Florida, the veterinarians have looked to us. It proved practicable for a public health laboratory to provide diagnostic service in animal as well as in human infectious diseases. Wherever there is no animal diagnostic laboratory, interdepartmental cooperation, rather than separate and independent laboratories, would be economic and advantageous.

No progress in providing aid in the diagnosis of virus infections, other than rabies can be reported from Florida's public health laboratories. These new and newly recognized entities are of increasing importance. It appears probable that within one to two decades it will be standard practice in public health laboratories to use tissue cultures and embryonated eggs as

well as serologic procedures and animal tests for rather routine diagnostic studies of virus diseases. State laboratories need to begin to provide opportunities for some of their workers to obtain training in the exacting field of virology.

Public health laboratories were developed as a result of the urgent pressure for the control of communicable diseases. There has been gratifying progress in this field and the laboratory has played an essential role. The goal of the virtual elimination of communicable diseases is beginning to be attained. In those infections in which there has been most progress in control, increasingly dependable laboratory diagnostic tests are required to identify accurately the residual infections. In such major diseases as tuberculosis and syphilis, there is much work ahead in satisfying the diagnostic laboratory needs; in others, notably the virus diseases, scarcely a beginning has been made. In communicable diseases, well acknowledged to be a responsibility of public health laboratories, there are still unmet needs and new opportunities.

In the above activities the laboratory is providing service to physicians, health officers, and epidemiologists. There is work also requested by sanitary engineers and sanitarians. There has been a recent marked increase in the examinations of water and milk in Florida. As local health departments have been organized in the State the quality of the water and milk available to the public has been checked more adequately. There are still localities in the State, and undoubtedly in every State, which do not receive this elementary public health protection. This work must continue and will undoubtedly expand.

New Responsibilities

The fluoridation of water has added a new responsibility. Periodic checks will be required at the water plants. It is the proper function of the public health laboratory to serve as a control laboratory; highly dependable findings on specimens submitted periodically will be required.

The chemical services appropriate for a public health laboratory are only beginning to

develop in Florida. At present this work includes: some diagnostic tests such as tests for protein in spinal fluid, hemoglobin tests which are given to the prenatal cases attending public health clinics, and check tests for the diabetes screening program. The service also includes the detailed chemical analysis of water and other miscellaneous chemical tests. But the toxicological problems are the ones of most interest and of highest importance, and their solution is a service needed by the law enforcement agencies of the States and their counties. Unless otherwise covered, this important field is open to public health laboratories.

The environment of the industrial worker properly receives special attention. Commonly, but in my opinion unfortunately, the industrial hygiene laboratory functions apart from the general public health laboratory. Concerned for so long with communicable diseases, the general public health laboratory was not well prepared for the responsibility of providing laboratory service to industrial hygiene units in health departments when that work was initiated. Eventually this work should be incorporated with the broadened activities of the public health laboratory. Such an arrangement will be economical, and with carefully selected personnel and desirable cooperative relationships it will be a more efficient organization of public health services than the widely prevailing present arrangement.

In the future it is probable that substantial attention will be given to air sanitation. Control of environmental pollution caused by radioactive substances may be required in many localities rather than in a few. The extent of laboratory participation in such activities cannot be estimated at this time.

In the past and largely at present, the public health laboratory has been and is a diagnostic laboratory performing simple tests in large numbers. In general, it has been given the type and number of personnel adequate only for this work. No laboratory can grow satisfactorily under these conditions. If laboratory personnel are to develop, and if laboratories are to retain able workers, satisfying opportunities for special studies must be provided. Moreover, there are numerous investigations which can be conducted only through public health

facilities. An urgent need for the public health laboratory is to attain a satisfactory balance between diagnostic services and special studies, a development which is still at a very early stage.

What of tomorrow's work in the chronic diseases? It is reasonable to expect that case-finding programs will eventually be accepted as a proper field of public health activity. Useful tests to indicate the probable occurrence of early malignancy or to detect chemical aberrations leading to arteriosclerosis could drastically modify the extent and character of laboratory work. When the Florida laboratory was organized, there was no serologic test for syphilis but now the performance of these examinations is a major activity. The early detection of predisposing causes or the early signs of chronic disease conceivably may be the major activity of the public health laboratory 50 years from now.

Educational Opportunities

In considering programs of the future, careful attention needs to be given to educational opportunities and responsibilities. It is well to examine programs of this type which have established their value in our sister bureaus. Seminars and short courses are an accepted part of the maternal and child health and venereal disease programs. More recently, educational programs of this type have proved notably effective in cancer, diabetes, and heart disease activities. They are designed solely to help the practitioner serve his patients better. Likewise, in the laboratory field, there are rich opportunities to aid clinical laboratory workers to provide more dependable and uniform results to the physicians they serve.

This will bring the public health laboratory into intimate contact with the medical technologists. Laboratory workers in the medical field need to develop as a professional body. There should be strong State and local organizations drawing together all those in this field who serve in hospitals, clinics, physicians' offices, private laboratories, public health laboratories, or elsewhere. In any such organization the bacteriologists, serologists, parasitologists and clinical chemists should join with the general

medical technologists. The public health laboratory is in a position to give leadership. Every influence must be used to assure that the strength of an organization of medical laboratory workers rests on its high educational value. In the future we can aid in bringing to maturity an allied professional body of high importance in the medical field. When this is attained, it will be natural to work with, or as a part of, this organized professional body and its allied State and local groups to improve the quality of laboratory practice—an activity which eventually should receive the endorsement and commendation of pathologists, medical practitioners, and the public they serve.

It has proved advantageous in Florida to work closely with laboratory personnel in the dairy industry. An annual refresher course giving detailed attention to selected problems, with opportunities for laboratory practice, has been received favorably. Representatives of the State Department of Agriculture, the dairy science division of the University of Florida, and the State Board of Health cooperated in planning the course which has served to draw together technologists from the dairy industry and the public health "control" laboratories. The initiative and leadership in this activity came from the State public health laboratory.

Educationally, there is a continuing need to participate in discussions at meetings of physicians, nurses, sanitarians, and others who use public health laboratory services.

Personnel Practices

The development of laboratory programs and planning for laboratory personnel must go hand in hand. There have been gratifying advances in personnel practices in public health. Retirement plans offer inducements for long-term career service. Salaries have been raised to a more adequate and equitable basis. These are some of the favorable features, but there are also weaknesses and problems.

Under any plan providing for slow advancement in long-term careers, there is always the possibility of losing the better workers, and, through personnel seniority policies, the possibility of having the less ambitious, the less imaginative, and the more easily satisfied per-

sons in senior positions. The only solution to this potential problem is its prevention. There must be greater flexibility to permit the rewarding of exceptional persons; there must be even greater care in personnel selection, and especially in promotion to positions of senior responsibility.

Stagnation is a real hazard of career service and a particular risk to those in repetitive routine activity such as in the laboratory where large numbers of the same tests are performed day after day. There are safety devices here. Academic advancement is to be encouraged. We have been highly pleased with a cooperative relationship between the Florida State public health laboratory and the University of Florida, which permits promising junior workers to accumulate academic credits while employed and, equally important, which requires senior workers to teach. The limited investigations required for the master's degree thesis has stimulated keen interest in these activities. Workers advancing academically who are given opportunities and encouragement in research will not stagnate.

Laboratory work today is teamwork, not individual activity. This accentuates the importance of the problem of personnel management. The reliability of laboratory findings varies with the worker's emotions as well as his ability. Directors or departmental chiefs are managers of laboratory teams and need a sympathetic understanding of human emotions quite as much as technical skill and scientific knowledge. The laboratories of the future must be recognized above all as groups of human beings working together. Facilities, equipment, and reagents are required, but harmonious teamwork, just as much as material tools, determines the dependability of findings.

Summary

The record of the past has been written. During the first chapter of the history of the public health laboratory, attention was concentrated on the acute communicable diseases. Tests at first were employed largely for confirmation of diagnosis; later they were used in increasing numbers for case finding and the detection of carriers. More exacting tests by more expert personnel became essential for the

accurate identification of residual infections.

Major emphasis is directed to the chronic infections during the second and present chapter of the history. The need for simple procedures for case finding and for more highly sensitive and specific tests for diagnosis has become evident.

For the future, there are numerous unexplored problems in viral and other infectious diseases. Ahead, there is a call for continuing and increasing work in sanitary bacteriology, a broad development in public health chemistry, closer integration of all laboratory services provided at public expense, new and expanding

work in chronic diseases, and an educational program designed to aid in improving the quality of medical laboratory service wherever it is performed. Special studies and active research programs will be required to encourage the development of laboratory personnel and to elevate the stature of the public health laboratory.

Looking to the future, we must obtain adequate facilities; acquire, train, and retain highly competent professional laboratory workers and aid each in attaining a highly satisfying and productive professional experience. Opportunities and needs of the future equal or exceed those of the past.

Amyotrophic Lateral Sclerosis

A major study of amyotrophic lateral sclerosis is under way on Guam where the disease is highly prevalent. The contributions of heredity and environment to the development of the disease will be investigated on the island which has a population that is relatively fixed. The National Institute of Neurological Diseases of the Public Health Service, the Bureau of Medicine and Surgery of the Navy, the Department of the Interior, and the Government of Guam are cooperating.

Amyotrophic lateral sclerosis is a degenerative disease of the nervous system which strikes most frequently between the ages of 30 and 55. There is no treatment for it. Its cause is unknown. Frequently assigned to the large class of demyelinating diseases of which multiple sclerosis is the best known, the disorder is pathologically characterized by demyelination of the brain and spinal cord—a breakdown of the fatty covering of nerve fibers. Popular attention was directed to it when Lou Gehrig, a baseball player, became one of its victims.

There seem to be two types: one, a slow progressive type primarily paralyzing the muscles of the hands and arms, and eventually affecting other organs; the other, a more rapidly progressive type, where shoulders, neck, tongue, lips, palate, and pharynx are initially involved and paralyzed. In the latter, the bulbar type, death by asphyxia or from aspiration pneumonia usually occurs within 2 years.

Whether amyotrophic lateral sclerosis is as prevalent on Guam as is believed, whether it is exactly similar to the disorder as it is known elsewhere, and what may be its possible cause or causes are objectives of the study. Neighboring islanders will also be studied to determine if the disease is typical for Guam alone or for other islands in the Marianas as well.

Cancer Morbidity Studies In Metropolitan Areas

Two out of five patients with newly diagnosed cancer will die within 1 year unless a better record of early diagnosis is made; more than 500,000 new cases of cancer will be diagnosed in 1953; but only half of these new cases will be diagnosed while the cancer is localized, according to estimates made by the biometrics section of the National Cancer Institute, Public Health Service.

The recently completed studies on cancer morbidity in 10 metropolitan areas indicate that the current outlook with respect to the survival of cancer patients is not favorable. That the survival of cancer patients depends largely on the stage of the disease at time of diagnosis—whether the cancer is localized or has spread beyond the primary site—is strongly pointed up by the reports. The more accessible the cancer site to direct examination, the greater is the opportunity for its early discovery. Half of all cancer involves sites accessible to direct examination. Exclusive of skin cancer, 48.2 percent of all cancers in females and 22.6 percent of all cancers in males are located in accessible sites.

Only 64 percent of newly diagnosed cancer cases survived 1 year, according to the studies. When skin cancers, which have a high cure rate, are excluded, the survival rate is reduced to 58 percent. Among cases diagnosed while the cancer was localized, 84 percent of the patients survived 1 year. This rate may be compared to the 1-year survival of the 58 percent who were diagnosed after regional involvement had

occurred and the 28 percent who were diagnosed after remote spread of the disease.

Cancer of the uterus provides a striking illustration of the effect of stage of disease at time of diagnosis on survival; the 1-year survival rates were 91 percent for localized cases, 71 percent for cases with regional metastasis, and 36 percent for those diagnosed after remote metastasis had occurred.

Except for skin cancers, the percentage of cases diagnosed while localized is low for cancer developing at sites accessible to direct examination. These sites are: skin, prostate, rectum, mouth and pharynx, thyroid, breast, and uterus.

In cancer of the breast, a highly accessible site, only 2 out of every 5 cases are diagnosed while localized (40 percent). The proportion is less than 3 out of 5 for cancer of the uterus (57 percent), and it is 1 out of 2 for cancer of the prostate (50 percent). For cancer of the rectum in both sexes, the proportion is less than 1 out of 2, or 45 percent for males and 46 percent for females.

The cancer morbidity series cover Atlanta, New Orleans, Birmingham, Dallas, San Francisco, Denver, Chicago, Detroit, Pittsburgh, and Philadelphia. These cities were originally surveyed by the National Cancer Institute in 1937-39 and were resurveyed in 1948-49.

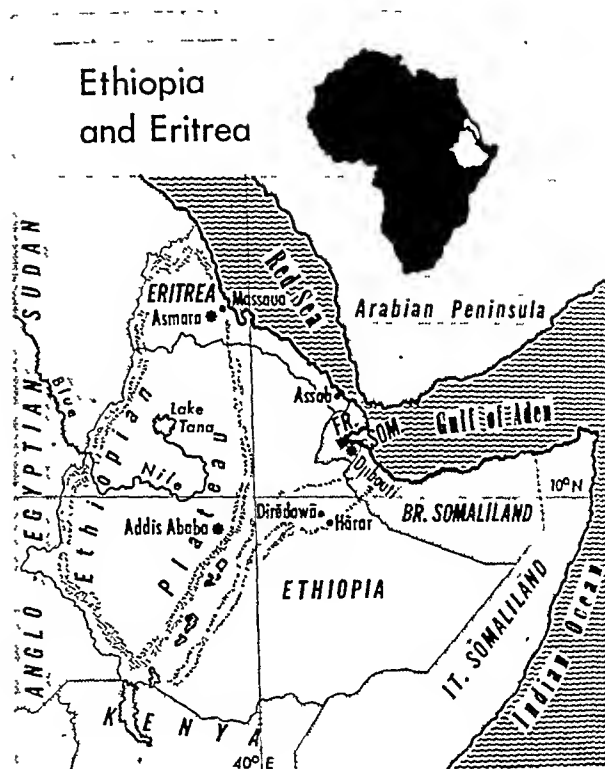

In preparation is a summary report which will provide comparative statistics for the two survey periods on cancer incidence, prevalence, and mortality as well as the relationship of cancer to such factors as primary site, sex, age, and race.

Separate reports of the 10 survey areas, covering both survey periods, have already been published. The reports on the 1948-49 series have been reviewed in recent issues of *Public Health Reports*. Inquiries concerning the series should be directed to the National Cancer Institute, National Institutes of Health, Public Health Service, U. S. Department of Health, Education, and Welfare, Bethesda 14, Md.

Mapping a Program Of Public Health For Ethiopia And Eritrea

By HENRY R. O'BRIEN, M.D., M.P.H.

Historically significant because of its fierce resistance to political and cultural invasion for 16 centuries, Ethiopia is today undergoing many crucial changes . . . Being officially welcomed are scientists, teachers, and health workers from other lands, who seek to introduce to this country the benefits of modern advances in medicine and public health . . . One of these public health workers reports his field observations on some of the health problems he found and some of his suggestions for their solution.

ETHIOPIA and Eritrea—politically independent, and since September 1952 federated by a decision of the United Nations General Assembly—are experiencing the ferment that has enveloped all Africa.

Both countries lie historically and geographically between the world of the Arabs, the eastern Mediterranean Sea, and equatorial Africa. Together, they form a rich agricultural reservoir of grain, cattle, and coffee.

In May 1951, a representative of the Technical Cooperation Administration (now a part of the Foreign Operations Administration) visited Ethiopia to discuss cooperative programs. Soon afterward, the Imperial Government of Ethiopia, through the American

Embassy in Addis Ababa, invited the Public Health Service of the United States to send a representative to Ethiopia to "recommend a specific project for public health preventive measures."

This report is an accounting of the observations of health conditions in Ethiopia and Eritrea and the recommendations which were made.

The Land and the People

Situated in the northeast corner of Africa, Ethiopia, known also as Abyssinia, is more than a third larger than the State of Texas. Its population is between 10 and 20 million.

Most of the country lies on a high plateau, reaching as high as 9,000 feet above sea level, and rising in sharp escarpments from the plains on the east and west and more gradually on the north and south. The plateau has been cut in deep gorges by the erosion of the Blue Nile, its tributaries, and other rivers, and is divided by the great Rift Valley.

The country is largely deforested. Heavy rains come in June through September, with lighter rains in February and March. Temperatures at 8,000 feet may fall from a high of 85° F. during the day to 40° F. in the early morning.

The size of the State of New York, Eritrea lies on the northern tip of the Ethiopian plateau. The high land gives way to an intermediate level on the east and west and then finally to the deserts of the Sudan (on the west) and to the narrow coastal plain along the Red Sea.

There is less water in Eritrea and more deforestation than in Ethiopia. Eritrea is a little warmer. Its roads and communications are noticeably better than those to the south in Ethiopia. Grains are the chief crop on the plateau, and some coffee is grown there. Cotton is raised in the western section. The people number between 1.2 and 1.8 million.

The ancestors of the Ethiopians came from southwest Arabia some 3,000 years ago, but the original Semites intermarried extensively with the Hamitic or Berber strains of northern Africa. Conquered negroid tribes are found in the south and west.

Some 40 languages are spoken in Ethiopia. Amharic is the first official tongue, and English the second. In Eritrea, the official languages are Arabic and Tigrinya, which is related to Amharic. In both countries, instruction in the schools, beginning with the fifth grade, is in English.

Ethiopia has long been a part of the eastern Mediterranean world—ever since Greek vessels sailed down the Red Sea. Christianity was first introduced in 350 A.D., and a Coptic Church developed, which has maintained itself in sturdy independence for 16 centuries. From the eighth century on, Moslem waves swept over much of the surrounding area and threatened Ethiopia again and again. Isolated by its

fiercely hostile neighbors, Ethiopia was known to Europe only through rumors as the "land of Prester John," the legendary medieval priest and king. Today, the people of both Ethiopia and Eritrea are Copts, Moslems, or pagans. These groups live together harmoniously.

In the European rush for territory in Africa during the late 1800's, Eritrea came under Italian control. Ethiopia was threatened with conquest too, but it remained independent until the Italian seizure in 1936. East Africa was liberated by British and other Allied armies in 1941. As a result of the long Italian occupation and the later British administration, the Eritreans are today more accustomed to Western ways than are the Ethiopians.

For the past century, the influence of the West has been increasingly felt in Ethiopia. Even when he was regent (from 1916 to 1930), Haile Selassie had started plans for the modernization of his country. His efforts were intensified on his coronation as Emperor in 1930. On his return from exile in 1941 after Ethiopia's liberation, the process began anew. The Emperor stresses education as the basis for general progress. He believes that advance must take place gradually on an even front—in health, education, agriculture, communications, and in-

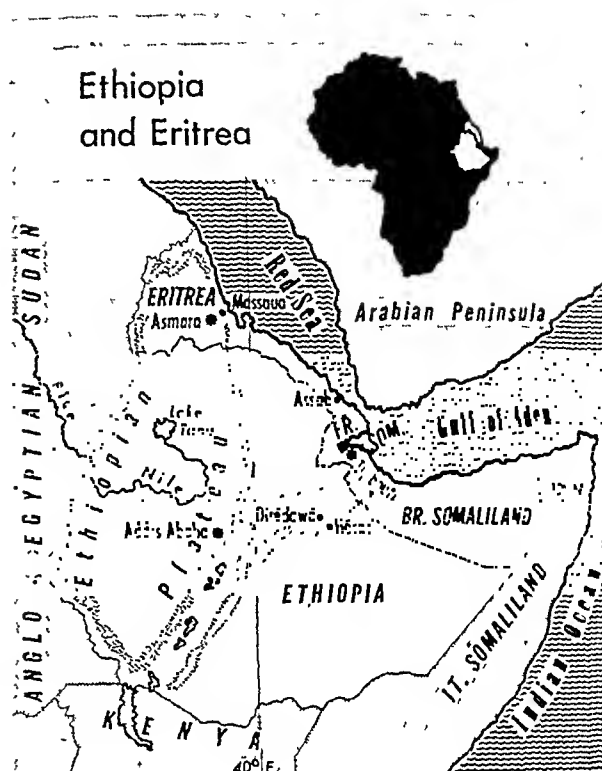

Dr. O'Brien bases his observations in this field report on the 3½-month survey of Ethiopia and Eritrea which he made in the latter part of 1952. Now a special assistant in Region III (Washington, D. C.) of the Department of Health, Education, and Welfare, Dr. O'Brien was formerly chief of the educational programs branch of the Division of International Health, Public Health Service.

Dr. O'Brien was stationed in Thailand with the Rockefeller Foundation at Bangkok from 1921-24 and with the McCormick (Presbyterian) Hospital in Chiangmai from 1926-30. During World War II, he visited 11 countries in the Near and Far East in connection with the medical activities of the United Nations Relief and Rehabilitation Administration. Between 1931 and 1943, Dr. O'Brien was engaged in State and local health work in Ohio, New York, and Connecticut. He is a commissioned officer in the Public Health Service.

The pictures in this field report are photographs taken by Dr. O'Brien.

Mapping a Program Of Public Health For Ethiopia And Eritrea

By HENRY R. O'BRIEN, M.D., M.P.H.

Historically significant because of its fierce resistance to political and cultural invasion for 16 centuries, Ethiopia is today undergoing many crucial changes . . . Being officially welcomed are scientists, teachers, and health workers from other lands, who seek to introduce to this country the benefits of modern advances in medicine and public health . . . One of these public health workers reports his field observations on some of the health problems he found and some of his suggestions for their solution.

ETHIOPIA and Eritrea—politically independent, and since September 1952 federated by a decision of the United Nations General Assembly—are experiencing the ferment that has enveloped all Africa.

Both countries lie historically and geographically between the world of the Arabs, the eastern Mediterranean Sea, and equatorial Africa. Together, they form a rich agricultural reservoir of grain, cattle, and coffee.

In May 1951, a representative of the Technical Cooperation Administration (now a part of the Foreign Operations Administration) visited Ethiopia to discuss cooperative programs. Soon afterward, the Imperial Government of Ethiopia, through the American

Embassy in Addis Ababa, invited the Public Health Service of the United States to send a representative to Ethiopia to "recommend a specific project for public health preventive measures."

This report is an accounting of the observations of health conditions in Ethiopia and Eritrea and the recommendations which were made.

The Land and the People

Situated in the northeast corner of Africa, Ethiopia, known also as Abyssinia, is more than a third larger than the State of Texas. Its population is between 10 and 20 million.

system in Ethiopia, and Addis Ababa has telephones and a radio station.

At a weekly market, to which people walk from miles around, a vendor may be seen selling little measures of salt brought up from the desert plains along the Red Sea. Another sells factory-wrapped cakes of soap of a well-known brand. Hand-forged spearheads are displayed in another part of the market and both foreign and domestic cloth in still another.

Some 15 communities, from the capital of Ethiopia to a small village, have public water supplies. Most of these are inadequate, and equipment is wearing out. Otherwise, the housewife carries water, often over long distances, in a clay jar from a spring or stream or waterhole. There are some septic tanks and pit privies in Addis Ababa. The municipality also collects rubbish. Harār has a few public comfort stations.

Health Conditions in Ethiopia

Although there are no epidemics at present in Ethiopia, the country is steadily drained by major endemic diseases. Syphilis and malaria, gonorrhea and the pneumonias seem to be the most prevalent. In the highlands, malaria follows the end of the rains. Lower down, it is endemic. Louseborne typhus is widespread: 8 cases were noted in 1 ward of a 100-bed hospital. Flea- and tick-borne typhus are also present. Relapsing fever is endemic. Amebic and bacillary dysentery are prevalent. Cerebrospinal meningitis appears in local epidemics from time to time. Tuberculosis is a serious problem and has increased since the Italian occupation. One estimate for the number of leprosy cases is 15,000.

Next to syphilis, wounds are the condition most frequently reported by the clinics. Trachoma, conjunctivitis, tropical sores, and rheumatic conditions follow. There is general malnutrition resulting from deficient diets and from periodic fasting. Some maternal deaths occur, most frequently from hemorrhage. Infant mortality is high. The village midwife is strangely absent in Ethiopia, but some training in midwifery has started in Addis Ababa. Instruction began in Asmara (Eritrea) some years ago. Scabies is widespread.

Ethiopia's Health Services

Public health first took a definite place in the Government of Ethiopia in 1942 as a bureau in the Ministry of the Interior. In 1947, the bureau became the Ministry of Public Health, which today is the center of health work in Ethiopia. The effectiveness of a health unit is measured by its organization, its program, its personnel, and its budget. Studied in each of these phases, Ethiopia has made distinct beginnings, but the country still has pressing needs.

The existence of a Ministry of Public Health is in itself a distinct achievement. There are now an acting Minister of Health and an experienced Director-General who handle administration for the Ministry. A Swedish physician with the title of Inspector-General serves as adviser to the Ministry. He is a trained public health worker who is devoted to Ethiopia. He speaks both Amharic and Galla. There are at present no Ethiopians in the country who are doctors of medicine. The Ministry has on its staff only 2 Ethiopian workers who are trained in public health: 1 had training in sanitation, and the other in statistics.

In the central office of the Ministry, there are separate bureaus handling administration, sanitation, statistics, foreign quarantine, and medical services. The bureau of medical services operates most of the hospitals in the country, either directly or by contract with one of the foreign missionary groups. The curative work of the Ministry, functioning through the hospitals, is at present its leading activity. Ethiopia has 38 hospitals with 2,315 beds (0.15 per 1,000 estimated population) and 3 leprosariums with 800 patients. There are some 80 physicians in Ethiopia, all foreigners, or 1 per 200,000 people.

The Ministry of Public Health places little emphasis on preventive medicine, although a good central laboratory for vaccine production and research and diagnostic work is developing in the Pasteur Institute of Ethiopia, an autonomous organization technically supervised by the Pasteur Institute of Paris under a contract with the Ministry of Public Health. The Institute also operates an anti-epidemic service, a function which gives it nominal supervision

established. The growth of basic nursing services will depend largely on the continued development of secondary education. Nurses are licensed by the Ministry of Public Health, and a nursing council is active under the medical education board.

Definite plans for local training of physicians are now under way. University College, which opened in Addis Ababa during 1950, accepts students who have passed the matriculation examination. It offers what seems to be a good premedical course and was to have been appraised by an accrediting committee from London in March 1953.

Meanwhile, funds have been collected from government workers to build the Haile Selassie I University in Addis Ababa. The university will have a faculty of medicine. A European businessman recently willed \$750,000 in Ethiopian currency (US\$300,000) for the new university. Bids have been invited for the first building which will include space for the first 2 years of a medical course. More than Eth\$3,500,000 is in the bank for this building. (Eth\$1.00 has an exchange value of US\$0.40.) Classes are planned to start in October 1955, and an enrollment of perhaps 8 students in the first year of medicine is expected.

There are 2 schools of dentistry in Addis Ababa, 1 under the Municipal Department of Health, the other under the sponsorship of the former Minister of Public Health. Neither school has much in the way of equipment, curriculum, or faculty. The teeth of Ethiopians are excellent, and the country has much more pressing health needs than the early development of dental education.

With plans made and training under way for physicians, nurses, and dressers, there is no present provision for an intermediate type of health worker, who has much more training than a dresser receives and less than is required for a physician, to assist the latter and supervise the former.

Budget for Health

The present budget for the Ministry of Public Health is Eth\$3,000,000 (US\$1,200,000). With this the Ministry maintains its hospitals and other health work. It is evident that if the Ministry is to furnish the preventive med-

ical and health services which the country so greatly needs, it must obtain additional funds. Ethiopia is at present operating within its means, aided by today's favorable price for coffee. Funds are being found for other worth-

(Top) A pumphouse of the municipal water system at Jimma (Ethiopia). About 15 communities in Ethiopia have public water supplies. Wells and springs are more common sources of drinking water.

(Below) Mother and child outside the municipal clinic at Asmara (Eritrea). Infant and prenatal care and other health services are provided at this clinic.

while projects in the Government. It is probable that when sound proposals are advanced by the Ministry of Public Health, with a prospect of professional and financial support from outside, approval of the Ministry of Finance and of the Emperor can be obtained.

The Recommendations

After consideration of these and many other points, and after discussing them with the Swedish adviser to the Ministry and with the representative of the World Health Organization, a tentative program was outlined for specific public health measures in Ethiopia. This was gone over orally with the chief of the TCA mission in Addis Ababa, and with his approval was presented to the Director-General of Health and to the Director of the Central Planning Board. Their advice was sought and their reactions were noted for use in the final recommendations. The final report was addressed to the TCA chief for transmission to the Ministry of Public Health.

In substance, the program included five recommendations:

A demonstration health department and field training school for medical assistants to be set up in one of the provinces, with cooperative support in supplying both staff and equipment from the Ministry of Public Health, the Technical Cooperation Administration, and the World Health Organization.

Three health workers to be assigned by TCA for immediate needs—a sanitary engineer to work with the Ministry of Public Health to improve community water supplies, another to be stationed by the Ministry in the Addis Ababa Municipal Department of Health, and a health educator to be loaned by the Ministry of Public Health to the Ministry of Education for training of teachers in school health.

More fellowships abroad in professional fields where such training is not available in Ethiopia. Properly used, such fellowships can advance public health in Ethiopia by a good many years.

A limited amount of badly needed equipment and supplies for the schools of nursing, and medical journals and reference books for the hospitals.

A chief of the health section of the TCA mission to maintain contact with the Ministry of Public Health, the World Health Organization, and the Technical Cooperation Administration for coordinating the above activities and for supervising the smaller health programs requested by Eritrea. He would also aid in plans for the medical school.

Eritrea's Needs

Only a week was available for a study of Eritrea, but that time permitted visits to the health institutions and to several schools in Asmara, and to a regional hospital, a health center, and a dresser station in the provinces.

A local government committee had worked out a possible health program with the TCA deputy director for Eritrea. It gave high priority to a request for schools of nursing, midwifery, and laboratory technique to be started at the 1,000-bed Civic Hospital in Asmara and also asked assistance in setting up a small leprosarium near Asmara.

As a result of the visit, the local requests were strongly indorsed as urgent steps, and suggestions were made for carrying them out as an interim program. One instructor was recommended for each of the three schools requested.

Acceptance of Proposals

From the point of view of technical cooperation, a study not followed by operations is sterile. The proposed program for Ethiopia was submitted by the Technical Cooperation Administration in Ethiopia to the Ministry of Public Health. The proposals were considered by the Central Planning Board and finally were placed before the Emperor.

As a result of the Emperor's approval, an agreement for cooperation in the field of health was signed by the Technical Cooperation Administration and the Ministry of Public Health at the end of April 1953.

What changes will come to Ethiopia and Eritrea after the proposed health programs have been put into operation remain to be seen. The study of the two countries and the recommendations which followed it are an earnest effort to help both Ethiopia and Eritrea at a strategic period in their development.

Cancer of Accessible Sites

"Half of all cancer involves sites accessible to direct examination," a new cancer control exhibit, was first shown at the annual meeting of the American Medical Association in New York City, June 1-5, 1953. Available for the use of medical societies, health departments, health associations, or any meetings of physicians, the exhibit is designed to encourage the early diagnosis of cancer. It points out to general practitioners the accessible cancer sites in both sexes and charts the percentages of all cancer occurring in these sites (see p. 975).

The exhibit has edge-illuminated, transparent male and female figures on a blue background. Easily assembled by one man, it has blinking lights and a shelf to accommodate publications. No transformer is necessary with a. c. current.

A threefold leaflet (Public Health Service Publication No. 324) is a facsimile of the exhibit.

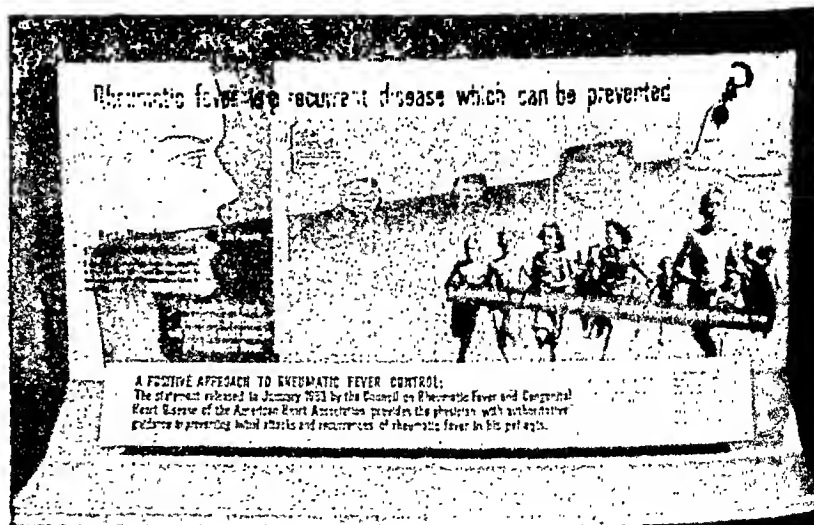

Rheumatic Fever Prevention

That "rheumatic fever is a recurrent disease which can be prevented" is stressed in an exhibit developed by the Public Health Service in cooperation with the American Heart Association. Based on the statement released in January 1953 by the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association, the exhibit illustrates the pattern commonly observed in a typical case of rheumatic fever. It underlines the fact that year-round daily doses of sulfonamides or penicillin will prevent most recurrences of the disease.

Designed for professional audiences, the exhibit has been shown at the annual meetings of the American Academy of General Practice in St. Louis, Mo., the American Heart Association in Atlantic City, N. J., and the American Medical Association, New York.

Specifications: 1 panel 8 by 6 ft. in 2 sections; requires 8 ft. floor space and 1,000 watts a. c. Assembling instructions included with shipment. For loan, apply to: Cancer Reports Section, National Cancer Institute, National Institutes of Health, Public Health Service, U. S. Department of Health, Education, and Welfare, Bethesda 14, Md. Borrowers must pay insurance and shipping costs both ways. Shipping weight 560 lbs.

Specifications: 1 panel 10 by 7 ft.; requires 10 by 6 ft. floor space; one 110 volt a. c. outlet. Assembling instructions provided. For loan, apply to: Division of Chronic Disease and Tuberculosis, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C. Borrowers must pay insurance and shipping costs both ways. Shipping weight 300 lbs.

Epidemiological Study Of Plantar Warts Among School Children

By WALTER K. GRIGG, M.D.
and GERTRUDE WILHELM, R.N.

AN EPIDEMIOLOGICAL STUDY of plantar warts among children attending the public schools in Dixon, Ill., was made by the school authorities and the Lee County Health Department during the school year 1951-52. The purposes of the study were (a) to determine whether or not an epidemic of plantar warts existed, and (b) to attempt to find significant factors in the epidemiology of plantar warts so that recommendations to prevent further spread might be made.

Despite the fact that plantar warts (*verruca plantaris*) are seen frequently in the general practice of medicine, relatively little has been written about them. The term plantar wart refers to any verruca located on the plantar surface of the feet. These warts may be single or multiple, multiple warts having either a haphazard distribution or that of a large wart with satellites (mother-daughter). The usual plantar wart is a hard yellowish or grayish lesion embedded in a small or large amount of hyperkeratotic tissue. On occasion the keratotic tissue may proliferate so freely that the lesion may be thought to be a callus. A diagnosis of verruca may be made if small black dots are found where the lesion is pared. These black dots represent vascular loops in the papillae of the corium and constitute the core of the wart.

Most plantar warts are presumed to have the same etiology as warts on other parts of

the body (*verruca vulgaris*) (1). When they grow on a pressure point of the sole of the foot, however, most growth must be inward. Severe pain and disability may result, particularly if the plantar fascia is invaded. Possibly of different etiology are the mosaic plantar warts, which are flat and nonpainful and which have irregular outline. Paring of these warts reveals many individual cores, forming a pattern which leads to the term "mosaic." Mosaic plantar warts frequently occur in association with hyperhidrosis (2).

Attack Rate

The feet of all children attending the public schools in Dixon were examined at weekly intervals during the school year 1951-52 by the school nurse and physical education instructors. In a school population of 2,389 students, 107 cases of plantar warts were discovered, an attack rate of 4.47 percent. For each of the 107 cases, an epidemiology card was prepared and filled out. A statistical analysis of the information obtained from these cards is given in table 1.

As a control measure, it was necessary to determine whether the attack rate in the Dixon schools was an epidemic rate. The school children in the neighboring town of Amboy were therefore examined in May 1952. In a school population of 275, only 2 cases of plantar warts were discovered, an attack rate of 0.72 percent. The two groups being comparable, a difference of 3.75 percent between the rates represents a standard error of difference of 0.6653 percent.

Table 1. Number of cases of plantar warts and attack rate among city school children in Dixon, Ill., by school, 1951-52

School	Number of students	Number of cases	Attack rate (percent)
Loveland (grade school) . . .	128	4	3.13
Lincoln (grade school)	719	25	3.48
North Central (grade school).	469	16	3.84
South Central (grade school).	429	22	5.13
Dixon High School	644	40	6.21
All schools	2,389	107	4.47

Dr. Grigg, now in general practice of medicine in Batavia, Ill., was at the time of this study acting health officer of the Lee County Health Department, Dixon, Ill. Miss Wilhelm is the school nurse of the Dixon public schools.

Table 2. Number of cases and attack rate of plantar warts among students in grades 4 through 8, according to availability of showers

School	Number of students	Number of cases	Attack rate (percent)
Showers available			
Lincoln.....	382	22	5.76
South Central.....	217	18	8.29
Both schools.....	599	40	6.67
Showers not available			
Loveland.....	38	4	10.53
North Central.....	293	16	5.46
Both schools.....	331	21	6.04

Thus, the difference is well outside the realm of chance, and it is assumed that an epidemic of plantar warts occurred among the school children in Dixon. It is realized, of course, that a year-long survey of the children in Amboy, such as was conducted in Dixon, might have yielded a greater number of cases and a higher attack rate.

Availability of Showers

No showers were available for the students in the North Central, the Loveland, and the first three grades of the Lincoln and South Central schools. Showers were available for the remainder of the students. A comparison of the number of cases and the attack rate of plantar warts among students taking showers with the number of cases and the attack rate among students not taking showers is shown below:

	Number of students	Number of cases	Attack rate (percent)
Showers not available....	1,146	27	2.35
Showers available.....	1,243	80	6.44

The factor of age, however, must be compensated for in interpreting these figures since all students not taking showers were in grade schools, whereas the students taking showers were in both grade and high schools. Therefore, a comparison was made between the two grade schools with shower facilities and the

two grade schools without shower facilities, omitting the figures for the first three grades (table 2). A ratio of 0.38 exists between the difference in the attack rates for these two groups (0.63 percent) and its standard error (1.67 percent). Thus, the difference is so small in comparison with its standard error that showers are neither implicated nor absolved as a causative factor in the epidemic.

Both the Lincoln and South Central schools use foot baths and powderboxes in their shower rooms, and all showers and shower rooms are scrubbed nightly with a strong antiseptic solution. No statement can be made as to the effect that these preventive measures had on the attack rate since there was no group in Dixon with which to compare them.

Incidence by Sex and Age

As shown in table 3, there was a higher incidence of plantar warts among girls than among boys: 59.8 percent of the cases occurred in girls. The difference between the attack rate for girls (3.48 percent) and for boys (5.55 percent), 2.07 percent, bears a ratio of 2.44 to its standard error, 0.88 percent. This difference could occur by chance only about 7.3 times in 1,000 and is therefore significant. Watkins also reported a higher incidence of plantar warts in girls, 62.9 percent (3). No reason for the higher incidence in girls has been determined.

The greatest number of cases for all students occurred at age 15; the greatest number for boys, at age 14, and for girls, at age 15 (see chart).

Table 3. Number of cases of plantar warts, by sex

School	Number of students		Number of cases	
	Boys	Girls	Boys	Girls
Dixon High School.....	303	341	16	24
Loveland.....	66	62	4	0
South Central.....	234	195	11	11
Lincoln.....	394	325	4	21
North Central.....	238	231	8	8
All schools.....	1,235	1,154	43	64

Distribution of cases of plantar warts among school children in Dixon, Ill., by sex and age, 1951-52.

The following tabulation shows the number of students observed in each grade:

Grade	Number of students
Kindergarten	271
1	177
2	161
3	234
4	180
5	184
6	171
7	173
8	170
9	213
10	188
11	150
12	117

Other Data

The number of cases of plantar warts discovered in each month of the school year 1951-52 were as follows:

Month	Number of cases
(Before July)	3
July	3
August	5
September	5
October	6
November	4
December	6
January	10
February	20
March	23
April	17
May	5

The epidemiological investigation also revealed the following data: All 107 of the students with plantar warts participated in physical education classes. Thirty-six of these students participated in interscholastic sports; 71 did not. Ninety-three of the 107 students swam in the Dixon swimming pool during the summer; 14 did not.

Incubation Period and Etiology

Investigators have attempted to determine the incubation period of verrucae vulgares through inoculation experiments on humans. They have found the incubation period to be 1 month, 3 months, 6 months, 8 months, and 20 months. The fact that material from verrucae injected into the normal skin will cause a wart to appear is presumptive evidence that warts are caused by an infectious agent, though no etiological agent has ever been isolated from a wart. Most investigators believe the agent is a virus (1).

As a part of this study a number of specimens of plantar warts were removed surgically and sent to the University of Michigan Virus Laboratory for study. All efforts to isolate a virus proved unsuccessful.

Type of Warts and Location

No mosaic plantar warts were found. Seventy-nine students had single plantar warts; 28 had multiple warts. One interesting fact was that 11 students had verrucae on other parts of their bodies. The distribution of these lesions were: hands, 7; arms, 3; and knee, 1. The incidence of verrucae on the body among the general school population was not determined. However, the fact that 10.28 percent of the children having plantar warts had verrucae on other parts of the body, 91 percent on parts that probably would come in contact with the feet, appears significant.

Ninety-three of the 107 patients had one or more verrucae located on a pressure point—base of heel, longitudinal arch, metatarsal arch, or base of toes. This figure is considered significant. Many investigators have previously presented the theory that trauma is a significant factor in the etiology of plantar warts. The locations on the feet were: metatarsal arch,

Table 4. Incidence of plantar warts among other members of the families of children having plantar warts and of control group

Group	Number of letters returned	Number of families having other members with warts	Attack rate (per cent)
Families of children with plantar warts	30	7	23.3
Families of children without plantar warts-----	22	5	22.7

55; toes, 28; heel, 18; longitudinal arch, 6; and other parts of the foot, 11. (The total of 118 is due to the fact that some children had warts on several parts of their feet.) There were approximately an equal number of warts on the right and left feet.

Family Members Having Warts

Since plantar warts and verrucae vulgares are presumed to be infectious, the incidence of warts among other members of the family was investigated. A form letter was mailed to the parents of each student who had plantar warts, requesting that the feet and body of each family member be examined for warts. As a control measure, letters were also sent to an equal number of parents of school children not having plantar warts. The children in the control groups were of the same age and sex and in the same schools as the children with plantar warts. The results of this investigation are shown in table 4. There does not appear to be a significant difference in incidence between the families of the patients and the families of the controls.

Summary

During the school year 1951-52, 4.47 percent of the students in the Dixon public schools were discovered to have plantar warts. An examination of the school children in the neighboring town of Amboy in May 1952 revealed an attack rate of only 0.72 percent.

A comparison of schools where showers were not taken with schools where showers were taken

(and foot baths and powderboxes utilized) failed to reveal a significant difference in the attack rates.

Girls showed a higher incidence of plantar warts than boys. The greatest number of cases in boys occurred at age 14; in girls, at age 15.

The incubation period was not determined; the greatest number of cases, however, had their onset in February, March, and April.

Seventy-nine students had single plantar warts; 28 had multiple warts. Eleven of these students had verrucae on other parts of the body. The percentage of school children having verrucae on other parts of the body was not determined, but the fact that 10.28 percent of the children with plantar warts had warts on other parts of the body is considered to be significant.

Pressure points were the site of 86.7 percent of the plantar warts. Since trauma would most likely occur on a pressure point, trauma may be a factor in the development of a plantar wart, as has been suggested by many investigators.

Plantar warts are thought by the authors to be related to verrucae vulgares. Many investigators have shown that material from verrucae can be inoculated into the skin of the same person or other persons and produce verrucae, suggesting that warts are infectious. The University of Michigan Virus Laboratory was unable to isolate a virus from specimens of plantar warts sent to them during this study.

ACKNOWLEDGMENT

The assistance of the following persons is acknowledged: Dr. Charles F. Sutton, Dr. Jackson Birge, and Isabelle Crawford, Illinois Department of Public Health; Dr. Thomas Francis, Jr., and Dr. John Morley, University of Michigan School of Public Health; the principals and physical education instructors of the Dixon and Amboy public schools; and Fern Hicks, Mary Wheatland, and R. G. Thomas, Lee County Health Department.

A Program for Protection Of Research Employees Against Pathogenic Hazards

BY JAMES BLACK, JOHN M. LYNCH, M.D.,
and IRVING LADIMER

IN THE PROCESS of investigating complex medical and biological problems, laboratory personnel become exposed to a wide variety of potentially severe hazards created by the chemical, biological, and radiological materials they handle. At the National Institutes of Health of the Public Health Service, this is true perhaps to an even greater degree than in many laboratory organizations.

Laboratory-acquired infections have been a source of danger to scientists not only because of the difficulty of safeguarding against known pathogens in small, compact work spaces but, of more importance, because of the possible presence of unknown organisms. From the early days of the Public Health Service Hygienic Laboratory down to the present extensive network of laboratory and clinical facilities at the Institutes, concern for the safety of investigators and technicians has been paramount. Laboratory hazards of this type are, of course, not unique at the National Institutes of Health (1-4), but its management and control of the problem appear worthy of report.

The National Institutes of Health was among the first of scientific institutions to develop a comprehensive program, which, following a severe outbreak of Q fever among the staff, was symbolized by the construction of a special memorial laboratory. The building, designed especially for the safe study of highly infectious diseases, physically embodies an integrated safety-health program emphasizing prevention,

control, and accurate reporting. The program operates on a quiet day-to-day basis through the efforts of the investigators who by specific instruction and exhibition of good work habits provide continuous education for the technician.

The Institutes employ about 3,000 investigators and technical aides to increase knowledge leading to prevention and cure of neoplastic, mental, cardiovascular, neurological, dental, microbiological, and metabolic diseases. The problem of safety is a continuing one of high priority. To cope with this problem, emphasis is placed on integration of physical safeguards into all the newer buildings, on observation of safe operating techniques, and on application of medical controls for all employees engaged in hazardous tasks.

Promoting "Hazard-Consciousness"

All preventive programs at the Institutes are based on the principle that the supervisor is responsible for the maintenance of a safe working environment. He is aided in this responsibility by the safety engineer, the radiological safety officer, and the medical officer of the employee health service.

The safety engineer fosters the development of a comprehensive program to create an atmosphere for hazard-awareness at all levels of employment. Each institute has its own safety committee which acts as a liaison between the laboratory chief and the employees, makes periodic inspections, and recommends safe-practice policies.

Protecting Against Pathogens

Although the safety committees of the National Institutes of Health concern themselves with all phases of safety, only the precautions used to minimize the possibility of infection from pathogenic organisms are described here.

Microbiological operating techniques necessitate a myriad of safe practices that form an integral part of procedure but which are rarely presented in the literature. Especially, for the benefit of new workers, one of the chapters of the National Institutes of Health manual, *Safe Practices*, contains a guide to safe microbiological practices, some of which,

Mr. Black is the safety officer, Dr. Lynch, the medical officer in charge of the employee health service, and Mr. Ladimer, the assistant to the director, research planning branch, at the National Institutes of Health, Public Health Service.

relating to aerosols, are outlined below. This guide consists essentially of a recording of safe techniques developed by the investigators and technicians over a period of many years.

1. All glassware containing infectious materials must be autoclaved before it is sent to the central glass wash unit. It cannot be left in the autoclave room unattended, and the can containing the glassware must bear an identification form (fig. a) showing the investigator's name and the length of time the material has been sterilized. Such equipment as broken syringes, broken glassware, or capillary pipettes that are likely to cause accidental lacerations or inoculation of the glass-room personnel should be autoclaved separately and discarded in "broken glass" receptacles.

2. Waring blenders containing infectious materials must be operated behind the closed sash of an exhaust hood (fig. b). Four vertically positioned ultraviolet lamps automatically turn on when the sash is lowered, and the exhaust chamber is provided with an electrically heated sterilizer.

A red jewel light indicates when the sterilizer element has attained its operating temperature of 700° F. Unless proper procedure directs otherwise, the blender should not be opened immediately after its operation. Other recommendations to minimize the danger of aerosol hazards are:

Modify blender to provide vaccine stopper to allow fluid to be drawn off without opening top.

Perform operation in a sterile chamber that can be decontaminated by one person in case of accident.

Provide a light plastic cover to prevent spraying of the hood chamber in the event a leak develops in the rotor bearing.

In the use of centrifuges, particularly where higher than usual speeds are involved or long periods of centrifuging are necessary, it is a good idea to make a preliminary check of the actual glass centrifuge tubes that will be used with the infectious agent.

3. When infectious material is being filtered, a trap containing an appropriate germicide should be placed between the filtering appar-

atus and the source of vacuum (fig. c). To further decrease the possibility of contamination to the vacuum line or pump and to minimize aerosol formation when the apparatus is disassembled, cotton plugs may be placed in the filter flask side arm, in the glass connecting tube between the two flasks, and in the glass tube connecting the trap with the source of vacuum. It should be set up in such a manner that the complete system can be easily autoclaved at the end of the experiment or periodically.

4. While infectious materials are being handled, the needle end of the syringe should be placed in an empty test tube to protect the technician against accidental puncture (fig. d). This technique will also minimize the possibility of contaminating the needle and will prevent droplets of infected material from contaminating work surfaces.

Syringes of the Luer-Lok type are recommended. Needles should be kept sharp, held securely and accurately in place, and oriented to prevent accidental spraying of assistant. Extreme care should be exercised during intranasal inoculations. Flame-sterilizing of the needle assembly should be done with caution to prevent cracking of the glass cylinder.

5. New workers should be made conscious of the fact that infection can be spread easily by touching equipment such as doorknobs, drinking fountains, sink faucets, and telephones, or by touching their own faces. Workers handling infectious materials should not be interrupted by the telephone. Awareness of the potential hazards involved in smoking, eating, or storing lunches in areas where infectious organisms are being handled should be stressed to the newly assigned aides.

6. The ease with which infectious aerosols can be created is also stressed in the safety manual. Aerosols can be caused when long needles of small gauge are withdrawn from tubes, setting up vibrations, or when needles are withdrawn from vaccine caps unless guarded with a wet cotton pledget (fig. e).

After flame-sterilizing a needle, the operator should hesitate momentarily before plunging a hot needle into infectious material. No solution should be prepared by bubbling expiratory air through infectious liquid, nor should

Protection against pathogenic hazards.

liquid be blown from pipettes in a manner to cause an aerosol.

Medical Examinations

The medical officer of the employee health service provides periodic physical examinations, laboratory tests, X-rays, and immunizations for those employees who are working in areas where such services are required. He is responsible for notifying the individual employee of the date on which he should report for examination. At least quarterly, the laboratory chiefs are required to provide the medical officer with a list of all personnel who are exposed to infectious organisms, and, in coordination with laboratory chiefs, the medical officer determines the type and frequency of medical control to be used.

With these data on the specific locations and nature of the various organisms, the medical

officer keeps the maintenance organization informed concerning specific hazards. The maintenance department is responsible for restricting its employees from the locations specified by the medical officer until the maintenance men have received the proper health safeguard.

Periodic chest X-rays are made of all employees exposed to infectious diseases, such as tuberculosis and histoplasmosis, that produce demonstrable pathology before outward symptoms can be detected. Employees working directly in the tuberculosis research unit receive chest X-rays at 3-month intervals, while employees with patient-contact duties in infectious and tropical disease areas of the Clinical Center at the Institutes receive chest X-rays at 6-month intervals. In addition, individuals with arrested tuberculosis and those who have had recent intimate contact with known active tuberculosis patients, are given appropriate followup chest X-rays. Employees working

with or exposed to monkeys are followed closely by chest X-ray for early signs of tuberculosis, since it is now well recognized that monkeys may act as a serious source of tuberculosis. As further protection, the monkeys themselves are tuberculin-tested when they arrive at the Institutes and at 6-month intervals thereafter; positive reactors would either be transferred to the tuberculosis research unit or be eliminated from further research projects entirely.

All employees working with or exposed in any way to infectious disease agents in their work, are urged to come to the employee health service whenever they have any illness, particularly febrile illness. Thorough evaluation and followup is conducted to determine possible relationship with the working environment. Employees who become ill at home, and who are unable to come to work, are urged to call their family physician who may call, if he desires, the employee health service or the employee's supervisor for information regarding the working environment. In any event, the ill employee is urged to report to the employee health service as soon as possible.

All employees in infectious disease areas are asked to provide a blood specimen every 6 months. The blood is frozen and stored for study and for comparison with blood taken in

future examinations. In the event of suspected occupational disease, serums are then available for diagnostic paired studies and other determinations utilizing serum.

Every 6 months, a serology test is performed to check employees working with *Brucella*. All employees directly or indirectly exposed to Q fever are immunized. Employees are encouraged to have tetanus toxoid inoculations.

In general, any applicant for employment at the National Institutes of Health with a pre-existing condition, which would make him more susceptible than the average individual to infectious diseases, would not be assigned to areas where microbiological research is being conducted.

Grain Sanitation Committee Organized

An Advisory Committee on Grain Sanitation has been appointed by the Departments of Health, Education, and Welfare and of Agriculture to recommend a program to improve the cleanliness of wheat and to reduce economic losses caused by insects and rodents.

The work of the 17-member committee has been described by its chairman, Dr. Charles Glenn King, scientific director of the Nutrition Foundation in New York City, as a cooperative attack on the problem of grain sanitation by Government agencies, the grain, milling, and baking industries, and the agricultural colleges.

At the committee's organization meeting August 11, three subcommittees were appointed. The subcommittees and their chairmen are:

Subcommittee on Education, chairman, W. H. Bowman, representative of Millers' National Federation, Chicago.

Subcommittee on Rodent Control, chairman, Dr. Harold Macy, dean of the Institute of Agriculture, University of Minnesota.

Subcommittee on Insect Control, chairman, Dr. R. C. Smith, head of the entomology department, Kansas State College.

Frequency of Accidents as Recorded In Family Surveys

Public Health Monograph No. 14 contains three studies of accident reports based on monthly visits to the homes of families living in certain blocks of the original Eastern Health District of Baltimore.

The first study pertains to the general aspects of accident frequency. The second indicates that more accidents occur in the home than in public places or at work, but the risk of accident per million hours spent in the home is much less than the risk in public places or at work. The third study suggests that persons with chronic disease have more accidents during a specified period of observation than those who are free from such diseases.

Part I. *Accident Frequency by Specific Cause and by Nature and Site of Injury.*
By Selwyn D. Collins, Ph.D., F. Ruth Phillips, and Dorothy S. Oliver.

Annual illness of all severities and from all causes amounted in this study to 1,379 cases per 1,000 population, of which 125 (9 percent) were due to accidents. Of the 2,690 injuries in the 5-year period, 1,110 (52 per 1,000) disabled the patient for one or more days and the other 1,580 (73 per 1,000) did not cause loss of time from usual activities such as work away from or at home, housekeeping, or attending school.

In terms of total and of disabling cases, falls and miscellaneous ill-defined accidents were the 2 most frequent of 10 external causes. In terms of total accidents, lacerations, and superficial injuries were the 2 most frequent of 9 kinds of injury.

Falls are an important cause of both fatal and nonfatal accidents; motor vehicle accidents only exceed falls in fatal accidents.

The highest accident frequency occurs among children. Under 35 years of age, rates were higher for males than for females, but above 35 the reverse was true.

No. 14

The accompanying summary covers the principal findings presented in Public Health Monograph No. 14, published concurrently with this issue of Public Health Reports. The authors are with the Division of Public Health Methods, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Collins, Selwyn D., Phillips, F. Ruth, and Oliver, Dorothy S.: Accident frequency, place of occurrence, and relation to chronic disease. Public Health Monograph No. 14 (Public Health Service Publication No. 249). U. S. Government Printing Office, Washington, 1953.

A high proportion of all injuries involve some part of the head, particularly among children. In the ages under 5 years, head injuries occur three and five times as often among boys and girls, respectively, as the next most frequent site, hands and fingers. These injuries are mainly lacerations and superficial wounds rather than fractures.

The external cause of the accident was related to the nature and the site of the resulting injury. In nature of injury, fracture and joint injury combined was the highest category in four external causes of disabling accidents—motor vehicles, sports and recreation, falls, and miscellaneous external causes. Lacerations were highest in three external causes—falling objects, handling or striking objects, and in the use of hand tools. Lower extremity was the most frequent site of injury in five external causes—motor vehicle, sports and recreation, falls, falling objects, and other external causes; hands and fingers were the most frequent sites in three external causes—handling or striking objects, machinery, and in the use of hand tools.

All injuries of a given nature were examined to determine from which external cause they originated. Falls were either the first or second cause contributing to each of the four natures of injuries.

Part II. *Risk of Accident at Home, in Public Places, and at Work.* By Selwyn D. Collins, Ph.D.

Estimates of hours spent at home, in public places, and at work were made for the Baltimore surveyed population, with the aid of data from an intensive survey in Michigan. The observed accidents in the Baltimore group were classified by place of occurrence (home, public places, work), and accident frequency rates per million person-hours were computed for each of the three places. Such rates represent the risk of accident in each place rather than the volume of accidents.

According to the usual rates, which do not take account of the time spent in each place, home accidents in the Baltimore study were 27 percent above the simple average of accident rates in the three places; public and work accident rates were 8 and 19 percent, respectively,

below the average. When hours spent in each place are taken into account, the situation is practically reversed: the home accident rate is 41 percent below the simple average of the rates in the three places, with public-place and work accident rates 16 and 25 percent, respectively, above the average of the three rates.

Age adjusted frequency rates for all accidents per million person-hours for the ages 15 and over are lowest for home, next for public places, and highest for work accidents. Age-specific rates are reasonably consistent in indicating the same order according to the size of accident frequency rates. Children under 15 years and particularly under 5 years have extremely high frequencies of falls on sidewalks, streets, and other public places per million person-hours spent in such places. Women experience more home and public-place accidents, particularly falls, than men in the same places, but they experience fewer work accidents than men.

Rates of actual days of disability per million person-hours indicate the same general order of the results of accidents in the three places, that is, work accidents have the highest rates; public places, the next; and home, the lowest of the three.

Several indicators of the severity of accidents, such as the percentage of cases disabling for 1 day or longer, average days of disability per disabling accident, percentage of disabling accidents that had 100 or more days of disability, and the percentage of disabling accidents that were fatal, all indicate rather consistently that work accidents are generally most severe, public-place accidents next, and home accidents the least severe of the three groups.

Part III. *Relation of Chronic Disease and Socioeconomic Status to Accident Liability.* By Selwyn D. Collins, Ph.D.

This study deals with the relation of chronic disease and socioeconomic status to the frequency of accidents.

The presence of chronic disease apparently adds to the liability to accident for the individual afflicted with the disease. A consistently higher percentage of individuals who had

repeated accidents during a specified period had some chronic disease than was true of individuals who had no accidents. This statement is true not only for all chronic and all major chronic diseases combined, but is true also for important specific chronic diseases and to some extent for minor chronic diseases also.

Consideration of males and females separately shows the same relationship of chronic disease to accident frequency for each sex.

Data were available on accident frequency in relation to only a few socioeconomic factors. Annual accident frequency rates per 1,000 population and the percentage of individuals who

had repeated accidents within a given observation period were higher among manual workers of each sex than among professional-business-clerical workers.

Annual accident frequency rates per 1,000 population and the percentage of individuals who had repeated accidents within a given period were higher in the lowest income group than in the two higher income groups.

A higher percentage of individuals living in low-rent houses and of individuals living in low-value owned homes had repeated accidents than of those living in homes with higher rents or values.

Medical Research Fellowships and Grants

Awards for postdoctoral fellowships in cancer and medical research will be made in the early spring upon recommendation by the National Research Council. Applications for any of the following 1954-55 programs may be made by citizens of the United States, unless specifically noted, and must be mailed on or before December 10, 1953:

Cancer research fellowships, awarded by the American Cancer Society for study in all branches of the biological, chemical, and physical sciences and of clinical investigation applicable to the study of typical or malignant cancer growth.

Exchange fellowships in specialized cancer research, awarded by the American Cancer Society to United States citizens for advanced study in Great Britain.

Fellowships in the basic medical sciences, awarded by the Lilly Research Laboratories and to citizens of the United States and Canada by the Rockefeller Foundation.

Tuberculosis fellowships, granted by the National Tuberculosis Association to promote the development of investigators in tuberculosis-related fields. Applicants must be United States citizens who are graduates of American schools.

Support by the James Picker Foundation of candidates who propose to carry on research relating to the diagnostic aspects of radiology. Appointments are not limited to citizens of the United States.

Also, institutions may apply before January 1, 1954, for one or more grants to scholars in cancer research. A grant of \$18,000 by the American Cancer Society, payable over 3 years, will be made to each scholar's institution as a contribution toward his support, his research, or both.

The fellowships are generally limited to candidates under 35. Information and application blanks may be obtained from the National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

Trend of Multiple Cases of Poliomyelitis In Household Units

By MORRIS SIEGEL, M.D., M.P.H., and MORRIS GREENBERG, M.D., M.S.P.H.

INTEREST IN the occurrence of multiple cases of poliomyelitis in the household was stimulated by the urgent need for basic preliminary data in formulating recommendations for the use of gamma globulin in familial contacts and by the long-range objective of studying the household as a basic social unit. Epidemiological study of family units is particularly applicable to poliomyelitis because of the heavy localization of infection in affected households and the close association between host factors and the disposition to paralysis (1-3).

Investigations within the home by others have revealed the common prevalence of infection among family members at the time of or soon after the first case develops as well as the rapidity with which the virus is disseminated among household contacts (4-6). Consequently, when multiple cases do occur, they usually appear within a very short time of each other (7).

The foregoing clinical observations were confirmed in a recent epidemiological study of household infections in New York City, in which detailed data on age, time intervals, and other factors are given (8). In addition it was shown that the frequency of multiple

clinical infections in the family was related to the number of susceptible persons in the household and to the annual attack rate of poliomyelitis. The association with incidence has been further explored in the present study because of its bearing on the evaluation of passive immunization in a community control program and on the broad problem of host-agent parasitism.

The method for determining the trend in the percentage of multiple cases during the year involved the tabulation by week of onset of (a) all reported cases, (b) first cases in families that had multiple cases, and (c) subsequent cases among the latter families. The difference between items a and c reveals the total number of newly affected families. This value divided into item b gives the weekly percentage of newly affected families with multiple cases.

Because of the newness of the approach, the results obtained by this method of tabulation are given by week of onset in the table for 1949 and for the endemic years combined. The households with multiple cases appeared to be fairly evenly distributed during the year in proportion to the total number of families affected. This was reflected in the weekly fluctuation of percentages above or below the annual average of 4.4 for 1949 and 2.7 for 1950-1952. As expected, the weekly deviations from the annual average are usually greatest when the number of reported cases is smallest, and can be reduced by accumulating the cases over broader periods.

The Data

The conditions of the investigation have been described previously (8). The data available

Dr. Siegel is associate professor, department of environmental medicine and community health, College of Medicine, at New York City, State University of New York, and Dr. Greenberg is director of the bureau of preventable disease, New York City Department of Health, and assistant professor of epidemiology, School of Public Health, Columbia University.

Figure 1. Poliomyelitis cases in newly affected households and percentage of newly affected households with multiple cases by week of onset (3-week moving average), New York City, 1949.

were 4,886 cases of poliomyelitis reported to the New York City Department of Health from 1949 through 1952. About 61 percent were paralyzed, and 39 percent had evidence of central nervous system involvement without recognizable muscular weakness. The cases reported occurred in 4,708 households of which 167 or 3.6 percent had more than one case per household. In the endemic years of 1950, 1951, and 1952, when the incidence in the general population varied from 6.8 to 13.1 per 100,000, the percentage of affected families with multiple cases fluctuated between 2.4 and 3.0. In the 1949 outbreak, when the incidence of poliomyelitis reached 31 per 100,000 population, the frequency of multiple cases was 4.4 percent. Because of these differences in endemic and epidemic years, it was deemed desirable to study the trend of multiple cases throughout the year. The clinical and epidemiological data analyzed were obtained by medical inspectors who visited the home of every reported case as well as the hospital.

The foregoing data by week of onset are presented graphically in figures 1 and 2. The fluctuations in weekly values shown in the table were smoothed by using the conventional method of a 3-week moving average. Thus,

each value shown on the graph represents the average number of households newly affected in the weekly period before, during, and after the specific week designated in the chart.

Horizontal Trend

In the epidemic year of 1949 the number of newly affected families each week rose sharply to a peak in the 32d week ending August 12, and then declined slowly (fig. 1). However, the percentage of those developing more than one case followed a horizontal trend which was elevated only at the onset of the outbreak, then dropped to a level maintained for 20 weeks until the end of the epidemic period. Consequently, while a rise and fall in the number of affected families was occurring, the percentage of those developing more than one case remained fairly constant during the epidemic except at onset when the percentage was unduly elevated.

The results observed in the endemic years from 1950 through 1952 are given in figure 2 in terms of an annual average for the 3-year period. That is, the data from the corresponding weeks of each year were combined, as shown in the table, and the average value for each week was used as representative of the period.

Poliomyelitis cases in newly affected households and percentage of newly affected households with multiple cases by week of onset in 1949 and in 1950-1952

Week of onset	1949			1950-1952		
	Newly affected households	Households with multiple cases		Newly affected households	Households with multiple cases

In the endemic years, a slowly progressive rise and decline in the number of newly affected families occurred during the summer and fall, and the percentage of households with multiple cases followed a horizontal trend. The number of new cases did not rise to the high levels observed in the 1949 epidemic, and the percentages of affected families with multiple cases were consistently lower than in 1949. It is further to be noted that the poliomyelitis

season was again ushered in by a rise in the frequency of multiple cases above average levels as had been observed in 1949.

Thus, the percentage of households with multiple cases appears to be fairly constant during the so-called poliomyelitis season, being higher in epidemic years than in nonepidemic years. In both periods, the percentages were somewhat elevated above their respective mean values at the onset of the poliomyelitis season.

Figure 2. Average annual cases of poliomyelitis in newly affected households and percentage of newly affected households with multiple cases by week of onset (3-week moving average), New York City, 1950-52.

Discussion

This study of the seasonal trend of multiple household cases of poliomyelitis has revealed some interesting features of theoretical and practical importance. The frequency of multiple clinical infections for a given year, expressed as a percentage of households with more than one case of poliomyelitis, was established early in the poliomyelitis season and was continued at a fairly constant level throughout the year regardless of seasonal fluctuation in incidence. From this standpoint, therefore, there was no evidence of a basic alteration in host-agent parasitism in the course of the seasonal rise and fall in number of reported cases. The data suggest that virulence as measured by the capacity to induce clinical infection among household contacts was not altered by serial passage in the human host under the natural conditions that prevailed during the study.

Several points of practical importance follow as a consequence of the foregoing observations. First, there was no evidence of an alteration in epidemic pattern arising from the control measures generally employed at the time. Otherwise there should have been a reduction in the percentage of households with multiple cases.

Second, the percentage of affected households with multiple cases could serve as a useful index for measuring the efficacy of a prophylactic agent, particularly when used during one part of an epidemic or in the absence of satisfactory controls. A favorable prophylactic effect should result in a measurable reduction in the percentage of household contacts developing clinical infection.

The increase in the percentage of multiple cases in the epidemic year of 1949 as compared with the 3 endemic years that followed was observed at the onset of the poliomyelitis season and continued throughout the summer. Such an increase might be used as an early index of epidemicity. However, our experience is limited to 1 epidemic and 3 nonepidemic years. If confirmed in other studies, its value in forecasting an impending epidemic should be further explored in conjunction with other methods thought to have predictive value (9). The practical value of the method might be limited because of the low frequency of multiple cases to large population groups or to areas of inordinately high attack rates (10).

The increase in the percentage of multiple household cases observed at the onset of the poliomyelitis season in epidemic and endemic

years may be apparent only. It may represent merely a variation due to small numbers or may be due to underreporting of cases in the general population. Selective reporting of families with multiple cases might be expected, particularly at the onset of the poliomyelitis season when the population has not yet been overly alerted, and would carry more weight in calculating percentages at that time when the total number of reported cases is low than later on when the totals are high. Unusual factors affecting the host and his environment were considered but could not be related to the change. Obviously, additional data are needed before its full significance can be properly evaluated.

Summary

1. The seasonal trend of the percentage of households with multiple cases of poliomyelitis was studied in New York City from 1949 to 1952, inclusive.

2. The percentage of affected families with more than one case of poliomyelitis for a given year was maintained at a fairly constant level throughout the poliomyelitis period despite the seasonal fluctuation in incidence, but was consistently higher in the epidemic year of 1949 than in the ensuing endemic years. This difference between epidemic and endemic years was discernible from the very onset of the poliomyelitis season.

Medical Practitioner Committee on Gamma Globulin

The Public Health Service has named a committee of seven practitioners of medicine to advise concerning the practical problems faced by the practicing physician in connection with the program of allocating gamma globulin for poliomyelitis. The group has been asked to interpret the allocation program through medical organizational channels so as to prevent misunderstanding, to evaluate the acceptability of the distribution plan, and to suggest desirable changes.

The committee held its first meeting in Washington September 10. Members are: Dr. Woodruff L. Crawford, Rockford Ill.; Dr. Edward E. Haddock, Richmond, Va.; Dr. Aims C. McGuinness of the School of Medicine, University of Pennsylvania; Dr. Herbert P. Ramsey, Washington, D. C.; Dr. A. M. Townsend, St. Louis, Mo.; Dr. Frank Wilson, director of the Washington Office of the American Medical Association; and Dr. Samuel M. Wishick of the Graduate School of Public Health, University of Pittsburgh.

National Evaluation Of Gamma Globulin

With the primary objective of measuring the effectiveness of gamma globulin in reducing the severity of paralysis in cases of poliomyelitis, a temporary National Gamma Globulin Evaluation Center has been set up within the Communicable Disease Center of the Public Health Service at Atlanta. The national evaluation center is also concerned with evaluating administrative and other phases of the national gamma globulin program. It does not distribute or administer the blood derivative. Dr. Abraham M. Lilienfeld, assistant professor of epidemiology at the Johns Hopkins University School of Hygiene and Public Health, is director of the national center.

Households where two or more cases of the disease occur are being chosen for special study, and all cases in selected epidemic areas will be investigated. Although it will be impossible to study all expected multiple case households in all States, as large a proportion as possible will be surveyed. Epidemic intelligence service officers, nurse-epidemiologists, and statisticians from the Communicable Disease Center have been assigned to the special studies. The study of multiple case households is already under way on a national basis. Epidemiological investigations in collaboration with State health departments have already been started in Alabama, Kentucky, North Carolina, Tennessee, and Virginia.

An advisory committee of 17 leading poliomyelitis authorities planned the investigation and will report on its progress. The committee is headed by Dr. Alexander D. Langmuir,

chief epidemiologist of the Communicable Disease Center, which is responsible for coordinating the national evaluation. Ten local and State health departments are represented on the committee.

Other members of the committee are Dr. John Chapman, epidemiologist; Los Angeles City Health Department; Dr. Roy F. Feemster, director, division of communicable diseases, Massachusetts Department of Public Health; Dr. D. G. Gill, State health officer, Alabama Department of Public Health; Dr. A. L. Gray, director of preventable disease control, Mississippi State Board of Health; Dr. Morris Greenberg, epidemiologist, New York City Health Department; Dr. Arthur C. Hollister, Jr., chief, bureau of acute communicable disease control, California Department of Public Health; Dr. Robert F. Korns, director, bureau of epidemiology and communicable disease control, New York State Department of Health; Dr. John D. Porterfield, director of health, Ohio Department of Health; Dr. Leonard M. Schuman, deputy director for division of preventive medicine, Illinois Department of Public Health; and Dr. Thomas F. Sellers, State health officer, Georgia Department of Public Health.

Also: Miss Lucy Blair, consultant, professional services, American Physical Therapy Association; Dr. Thomas Francis, Jr., professor of epidemiology, University of Michigan School of Public Health; Dr. William McD. Hammon, professor of epidemiology, University of Pittsburgh School of Public Health; Dr. John R. Paul, professor of preventive medicine, Yale University School of Medicine; Dr. Albert B. Sabin, director, Children's Hospital Research Foundation, Cincinnati; and Dr. Jessie Wright, medical director, D. T. Watson School of Psychiatry, Pittsburgh.

Arrangements for a muscle examination by a physical therapist of each case 50 to 70 days following onset of illness have been made with the American Physical Therapy Association, aided by a grant from the National Foundation for Infantile Paralysis. The gamma globulin is being made available by the Foundation and by the American Red Cross.

The program is sponsored by the Public Health Service in collaboration with the Association of State and Territorial Health Officers, the American Physical Therapy Association, and the D. T. Watson School of Psychiatry, which is affiliated with the University of Pittsburgh School of Medicine.

Based on material prepared by the National Gamma Globulin Evaluation Center, Communicable Disease Center, Public Health Service, Atlanta.

Organization and Administration of Bilateral Public Health Programs in Latin America

From the basic agreements which inaugurated the inter-American efforts, the evaluators traced the development of the Servicio concept and outlined its administrative characteristics. These efforts, they report, have been "directed toward developing in each country a health program best fitted to the needs of the particular country, staffed with well-trained nationals, and for which that country could eventually assume complete economic and technical responsibility."

THE RESOLUTION adopted by the foreign ministers of the 21 American Republics at their meeting in Rio de Janeiro in January 1942 recommended to the governments represented that individually or through bilateral or multilateral agreements the necessary means be taken to solve the environmental sanitation and health problems of the Americas, and that to this end each country, according to capacity, contribute raw materials, services, and funds.

Thus, it was recognized that no one nation, regardless of how favorable its economic position, could be expected to bring about any ap-

preciable change in the health conditions of the other nations by the provision of money alone. It was also recognized that the desired objectives could not be reached by any attempt by one nation to take over and run the health services of another.

The approach to the health and sanitation problems in Latin America, therefore, was to establish a program of assistance through cooperative efforts directed toward the strengthening of the existing health services of each country. This would require expansion of services and, in some cases, creation or complete rebuilding of services. All efforts of the cooperative program, therefore, have been directed toward developing in each country a health program best fitted to the needs of the particular country, staffed with well-trained nationals, and for which that country could eventually assume complete economic and technical responsibility.

This paper and the one following are the fourth and fifth in a series of excerpts from the report of the Public Health Service's evaluation survey of 10 years of operation of the Institute of Inter-American Affairs bilateral health programs in Latin America. Introductory notes concerning the objectives and limitations of the survey, a brief summary of the history of these programs, a résumé of the criteria and methods used in evaluating them, and a discussion of the cultural problems encountered were presented in the September issue of *Public Health Reports*, pp. 829-857.

Bilateral Agreements

The cooperative health and sanitation programs in each country have been inaugurated and developed through bilateral agreements. Out of the initial agreements between the

United States and Ecuador and the United States and Brazil in 1942, there evolved a pattern which generally came to be followed in all countries. Common to all programs were what came to be known as (a) the basic agreement, (b) the project agreement, and (c) the completion agreement. A summary of the chief features of these agreements follows.

Basic Agreements

The cooperative programs are initiated and extended by an exchange of notes between the United States ambassador and the foreign minister of the country involved which indicate the willingness of the respective governments to participate in a cooperative health and sanitation program. The notes authorize the minister of health and the representative of the Institute to draw up and sign an agreement stipulating the basic financial contributions and technical assistance to be contributed by each government and the general conditions under which the program will be carried out. This agreement, known as the basic agreement, is the contract between the two countries for the conduct of the cooperative program.

These agreements have taken two general forms: (a) An exchange of letters between an official of the Institute and the minister of health of the Latin American country, in which these two officials signify their agreement upon certain criteria as a basis for operating the cooperative program; or (b) a formal document drawn up and signed by the minister of health or his representative and a representative of the Institute. The latter technique came into general usage after a few years.

The provisions of the basic agreements, though varying in detail from country to country, have followed the same general pattern. The major provisions common to most agreements are as follows:

1. Provides for the establishment of a special unit of government in the host country to carry out the cooperative program. In Spanish-speaking countries this unit is usually designated as *Servicio Corporativo Interamericano de Salud Pública*, or *SCISP*. In nations where French or Portuguese is spoken, the designation is in the language of the country. The

word "*Servicio*," however, has become largely universal in usage.

2. Provides for sending to the host country a small group of United States technicians, called a field party, under the direction of a chief of field party. Most of the early agreements provided that the chief of party should be a doctor of medicine, but that provision has generally been eliminated.

3. Provides that the chief of field party will be the director of the *Servicio*.

4. Specifies the amount of money to be contributed to the cooperative program by each government and the period of time covered by the agreement.

5. Defines in some detail the area in which the program is to function, and specifies that the program is to be carried out on the basis of specific projects agreed upon in writing by the director of the *Servicio* and the minister of health or his representative.

6. Provides that the salaries and traveling expenses of the members of the field party will be paid directly by the Institute.

7. Defines the administrative authority of the director of the *Servicio* with regard to the employment of personnel, the expenditure of funds, and the accounting and reporting processes.

Thus, from the very beginning of the program in each country there has been a defined base of operation agreed to in writing by both parties. This has undoubtedly prevented many operational problems from arising and contributed immeasurably to the stability of the various programs.

The original agreements were usually brief, and some of the provisions were phrased in very general terms. As experience dictated, the agreements became more specific. In the beginning, they usually covered a period of 2 or 3 years, but after the war they were extended on a year-to-year basis. This made program planning and administration difficult, particularly since most Latin American countries operate fiscally on a calendar year and the United States appropriations usually come through long after the July 1 beginning of its fiscal year.

In 1949, Congress extended the life of the Institute to 1955, and it was possible to extend

the basic agreements for a 5-year period. The extensions covered all basic provisions except the amount of money to be contributed by the respective governments. Since this amount depends upon the appropriating bodies of the respective governments, it is necessary to amend the agreements yearly to indicate the respective contributions.

The model proposed by the Institute to be used as a basis for negotiating the 5-year extensions contained a significant statement of objectives:

"To promote and strengthen friendship and understanding between the peoples of the Republic of _____ and the United States of America and to further their general welfare;

"To facilitate public health and sanitation activities in _____ through cooperative action on the part of the parties to this agreement; and

"To stimulate and increase the interchange between the two countries of knowledge, skills and techniques in the field of public health and sanitation."

Project Agreements

The programs of the *Servicios* are carried out, for the most part, in the form of individual projects. When a particular activity is agreed upon, such as the construction of a water supply system for a village or a malaria control program for the entire country, a written plan called a project agreement is drawn up and signed by the minister or his representative and the chief of field party. This agreement defines the work to be done and allocates the necessary funds. If, because of unanticipated factors or errors of judgment, the cost of the project exceeds the original estimate, additional funds may be allocated in the same manner. The director of the *Servicio* usually has the authority to make the actual disbursement of funds within the provisions of the project agreements.

The first project to be agreed upon and signed by the respective officials in each country is known as the administrative project. It provides the funds for the establishment of the *Servicio* as a unit of government. The various administrative projects are periodically amended to provide administrative funds for continued operation and are usually terminated

only when the cooperative program is terminated.

The administrative project for Ecuador is typical. It provides funds for the salaries and traveling expenses of administrative personnel (exclusive of the United States field party), purchase of office supplies, communication expenses, purchase and repair of office furniture and equipment, rent for offices and storerooms, and other items of a general administrative nature.

Completion Agreements

As the name implies, the completion agreement is a document indicating the completion of a project. In this agreement, the minister and the chief of field party, who draw up and sign the document, agree that the work outlined in the project agreement has been completed and that the project is ready to be turned over to the appropriate governmental agency for continued operation. In many of the activities dealing with the training of personnel and perhaps the operation of certain facilities, it is impossible to draw a hard and fast line to indicate the point at which the project is finished.

The completion agreements are designed to provide a complete record of program accomplishments. Whereas the project agreement indicates the goals and plans for an undertaking, the completion agreement indicates exactly what was accomplished. These agreements, if properly maintained, provide a record of problems encountered in the course of the project operation, the techniques used to meet these problems, and the degree of success attained. The completion agreements become a history of the project and are of great value to the *Servicio* personnel in evaluating their own performance and in planning future undertakings. Likewise, they are of considerable value to the agency taking over the responsibility for the future operation of the project. Descriptions of methods which failed, as well as those which succeeded, should be recorded in these agreements to assist in future operations.

The completion agreements also provide a record of the actual expenditures made under the project agreements and any amendments. In addition to the amounts specified in the project agreements, they record any contributions made by third parties, such as municipalities,

states, private individuals, or private agencies. Such contributions may be in cash or in land, buildings, or personal services. The agreements further provide for the disposition of all property, equipment, or materials used in the development of the project.

Special Projects

An important part of the cooperative program consists of special projects which are financed completely from Institute funds and administered directly by the Institute. Special projects have been utilized in instances in which a worthy undertaking did not lend itself to bilateral action.

One of the major purposes of these projects has been the provision of scholarships and grants to Latin Americans for travel and study in the United States. Other special projects have included the translation of technical articles and books into Spanish; the furnishing of books to medical schools in Latin America; the purchase of blood plasma and its shipment to Guatemala for treatment of casualties during a revolution; the sending of sulfadiazine to Chile during an epidemic of meningitis; and the furnishing of advisory service to the Colombian Government in reorganization of the ministry of health.

Financial Contributions

The percentage of funds contributed by the United States to the cooperative health programs has varied considerably in the different countries, reflecting to some extent the economic level of the country. For example, in Venezuela the 1951 basic agreement called for a contribution of \$25,000 by the Institute and a contribution of \$502,500 by the Venezuelan Government to the basic program funds of the *Servicio*. However, the *Servicio* had a working arrangement with the Ministry whereby 75 percent of the cost of constructing water supply systems was paid by the government of the Venezuelan State in which a particular project was located. The *Servicio* contributed the other 25 percent. Therefore, on this basis the United States contributed roughly 2 percent and Venezuela contributed 98 percent of the funds.

The cost of the technical assistance supplied by the United States, however, approximated \$115,000, raising the United States contribution to approximately 8 percent and lowering Venezuela's to 92 percent.

In countries having a less favorable economic position than Venezuela, the percentage contributed by the United States has generally been much greater. For example, in Haiti, the United States contribution in money in 1951 was \$84,000 and the basic Haitian contribution was \$255,000, a ratio of 25 percent by the United States to 75 percent by Haiti. The cost to the United States for technical staff, however, was \$87,000; therefore, the United States furnished about 41 percent of the total cost of the *Servicio's* operations.

Technical Contributions

During the first years of the program, the United States contributed a high percentage of the technical and administrative knowledge and skill that went into the *Servicio* operations. The group of United States technicians, known as the field party, however, has usually numbered less than 10 people in each country. In addition to the chief of field party, who is either a physician or an engineer, the field party may include one or more of the following, depending upon program requirements: nurses, physicians, engineers, health educators, hospital administrators, industrial hygienists, and laboratory technicians. Each field party also includes a business manager, who has the responsibility for the business administrative functions of the field party and usually of the *Servicio*.

As Latin Americans acquired training and experience in the operation of the programs, the contributions of the various Latin American countries in technical skills greatly increased. On June 30, 1951, there were in all countries about 110 United States technicians in the health *Servicios* in comparison to 7,100 Latin Americans.

Third-Party Contributions

Through June 30, 1951, third-party contributions amounting to almost \$10 million had

been made to the cooperative health program. Most of these funds were contributed by local governments and local citizens groups as an inducement to secure *Servicio* assistance in some local project, such as a water supply or sewerage system, or a hospital or health center. As previously mentioned, the *Servicio* in Venezuela would not, by policy, undertake a project until a State, acting as a third party to a special project, should commit itself to contribute two-thirds of the funds.

In addition to the \$10 million contributed in funds, a conservatively estimated \$6.5 million contribution in other than cash has been made by third parties. Lack of uniformity in the reporting process among the various *Servicios* and the variety of forms which third-party contributions take make for difficulty in obtaining an accurate estimate. For example, in the construction of water supply systems in Honduras, villagers contributed their own labor to dig ditches and carried water pipe by burro. When the trails ended, they carried the pipe on their own backs over a range of mountains.

The value derived from third-party contributions is, of course, far greater than any monetary approximation would indicate. It has been well demonstrated in many countries that the monetary contributions are manifestations of the interest of the community in a project. Experience has shown that where the people of a community have had an active part in the planning, financing, and development of a facility, the chances for its continued operation at a satisfactory level of efficiency are much greater than where the people have not taken an active part.

Unfortunately, facilities have been developed by *Servicios*, perhaps upon a valid basis of need, but without sufficient attention to community understanding, encouragement of community participation, and careful evaluation of community economic status as related to financial ability necessary for maintenance.

The Servicio

The *Servicio* has come to be the trade-mark of the Institute of Inter-American Affairs. It is the administrative framework within which

the two countries which are parties to a bilateral agreement pool a portion of their economic and technical resources in order, in the case of health, to raise the health level of the host nation and promote, develop, and perpetuate a sound health program.

In most countries, the health *Servicio* is set up as a major operating division of the ministry of health. The director of the *Servicio* is on the same executive level as the directors of the other major divisions of the ministry, and organizational charts show the director of the *Servicio* reporting directly to the minister. The only exception to this pattern is in Chile, where the *Servicio* is within the National Health Service, and the administrative line runs from the director of the *Servicio* to the Director General of Health and then to the Minister of Health.

Field Party Members

Members of the field party occupy key positions in the *Servicio's* administrative structure. In all countries except Brazil, the chief of field party is the director of the *Servicio*. In some countries, other members of the field party hold administrative positions within the *Servicio* and are given official recognition by appointment by the national government; in others, by designation of the director of the *Servicio*. Although there has been no uniform definition of their administrative responsibilities with relation to the *Servicio's* national employees, the influence of the field party members on administration does not appear to have been greatly lessened by this lack.

The chief of field party as director of the *Servicio* generally has a dual administrative responsibility. As chief of field party, he is responsible for the supervision of Institute personnel in the field and for the Institute's participation in the cooperative program. As such, he is on equal footing with the minister of health in negotiating basic agreements and in determining the program to be followed by the *Servicio*. However, the chief of field party as director of the *Servicio* is subject to the administrative direction of the minister, at least theoretically, since the *Servicio* is a part of the ministry. There is a considerable variation from country to country as to how much administrative direction is given by the minister, but

in most countries it appears that the chief of field party has exercised very wide latitude in determining program content and in supervising its execution.

In Chile, the field party members, with the exception of the chief of field party, hold official positions within the *Servicio* but are designated as consultants to a national counterpart. The relative influence exerted by the different members of the field party on the administration of the program appear to depend much more on the individual's capabilities than on his official designation.

In Brazil, a national replaced the chief of field party as administrative head of the *Servicio* after the program had been in operation 2 years. The chief of field party, as the United States representative, continued to approve all expenditure of *Servicio* funds and served in an advisory capacity to the Brazilian director. As local counterparts of other members of the field party were trained to the point where they could assume the responsibility for direct program administration, the other United States technicians in Brazil also stepped aside and became consultants.

In some countries there would seem to be little justification for not training local personnel and transferring operational responsibility to them in a relatively short time. In others, because of such factors as frequent changes in government, general economic and political instability, and a scarcity of trained personnel, the process necessarily must be much slower. Every effort should be made in all countries to train local counterparts of the United States technicians, even though it may not be practicable to turn over complete administrative responsibility for some time.

Relationship to Other Ministries

Although the *Servicio* is an administrative unit of the ministry of health, some members of the field party are engaged in work as consultants to, or are closely associated with, another ministry or unit of government other than the ministry of health. For example, it is not unusual for a nurse consultant assigned to the field party to have as her primary assignment work with a school of nursing located in

the ministry of education or some other branch of government.

The *Servicio* may not only conduct a major program which involves working closely with another ministry, but it may actually be performing activities which would normally be performed by another ministry. For example, in Ecuador the *Servicio* has engaged in a large program of building water supply and sewage systems, an activity which would normally be performed by the ministry of public works. The *Servicio's* activities in that field have necessarily been closely coordinated with that ministry's activities.

It has become clear that the *Servicio* should be administratively attached to that ministry of government having the major responsibility for the field of activity for which the *Servicio* is established. In establishing *Servicios* in the field of health and sanitation in Latin America, the choice of ministries is fairly obvious, since most ministries of health have the major responsibility for public health and a substantial responsibility for hospital and institutional care. It is not unusual, however, to find education, welfare, health, and other functions in the same ministry. The *Ministerio de Previsión Social* of Ecuador, for example, has responsibility for public health, the federally administered hospitals, welfare, labor, and fire-fighting services.

It is of paramount importance that all activities of the *Servicio* be carried out in close collaboration with that unit of the national government which has the responsibility for the specific function or which will be expected to assume such responsibility at the time the *Servicio* can turn it over for local administration.

Principles of Administration

As there are great differences in the size and type of programs in the various countries, it is to be expected that organizational differences should exist. Even so, the various programs illustrate extremes both of well-organized operations with defined administrative lines of authority and responsibility and of poorly organized operations without clearly defined lines of authority and responsibility.

Proper supervision within a field party and

within a *Servicio* can be achieved only when the organizational structure is so defined that all employees have a clear understanding of their responsibility and authority, including their administrative "chain of command." It is extremely important that the chief of party give impartial and adequate supervision and con-

sultation to Institute and national personnel responsible for each type of activity. It is also important that the members of the field party keep the chief informed of developments in their programs, particularly if these developments are likely to have implications which would affect the total *Servicio* program.

10-year evaluation of the Bilateral Health Programs, Institute of Inter-American Affairs

The Servicio as an Administrative Device

EVALUATION of the *Servicio* as an administrative device for implementing the cooperative health and sanitation programs in Latin America necessarily took into account both the advantages and the disadvantages of this arrangement. No contention was made, however, that other administrative arrangements might not have served as well.

The characteristics of the *Servicio* considered advantageous include its continuous existence, its official status as an administrative unit of the host government, its large amount of freedom, from administrative controls of both the host government and the United States Government, and its stability. Thus, the *Servicio* provides an operational framework for technical assistance, facilitates the translation of plans into action, contributes to the training of nationals in technical skills, provides a base for indirect assistance to ministries other than the one in which it is established, and offers an opportunity for training nationals in general administration.

An Organizational Framework

Since the *Servicio* is an actual administrative unit of the host country, the technicians arriving from the United States have an established base of operations, with facilities for office space, clerical assistance, supplies, telephones, and related supplies and services. Of even greater importance is the fact that the *Servicios*

have existed in most countries as a stable unit of government for 10 years, thus permitting the establishment and maintenance of lines of communication and contact between *Servicio* personnel and all other officials and offices of the host government.

A large body of knowledge exists within the *Servicio* personnel regarding the operations of the host government which may affect the work of the *Servicio*. Knowledge of local protocol and of the methods and channels to be followed for the most expeditious application of the technical skills represented in the field party is preserved, even though the personnel of the field party changes.

Official Status

Opportunity for accomplishment of objectives by the field party is greatly enhanced by the official status accorded the *Servicio*. Such status opens many doors and makes available many operational facilities which otherwise would not be, at least without time-consuming negotiations.

As an official part of the national ministry, the *Servicio*, under the direction of the chief of field party, is in a position to carry out an operational program. Thus, once the minister and the chief of field party have agreed upon a program, the skills of the technical personnel may be applied to demonstrations under controlled conditions. Operational decisions may

be made largely without regard to political considerations. With the administrative direction of the program under the direct control of the technical group, it is possible to avoid many costly, time-consuming, and faulty operational decisions which are inevitable if responsibility rests with an untrained or inexperienced administrator. This factor was important in all countries early in the program and is still of paramount importance in many countries.

Special Operational Facility

In the agreements between the United States and each Latin American country in which *Servicios* have been established, there are provisions which make it possible for the *Servicios* to operate in a preferential setting. The authority of the chief of party to approve projects and put them into operation without prior clearance with the Institute makes possible the rapid translation of plans into action. At the same time, the *Servicio* is largely freed from the administrative controls and "redtape" of both the host government and the United States Government.

In many Latin American governments, procurement procedures are extremely involved. It is usually necessary to prepare a series of documents in multiple copies and to have them approved by a host of officials. More often than not, this process requires the final signature of the minister in order to procure anything from a postage stamp to a shipload of construction supplies. Many of the procurement procedures of the United States Government are only slightly less involved. The *Servicios* are in large degree freed from such procedures by the provisions of the basic agreements. As a result, they are able to secure supplies and transform work plans into action with a promptness previously unknown to most governmental agencies.

Most basic agreements also give the *Servicios* a high degree of autonomy with regard to personnel practices, accounting and recordkeeping, and other administrative activities. Thus, the *Servicio* can adopt or demonstrate the advantages of practices of the host government in fields which are appropriate.

Continuous Operation

The fact that the *Servicio* was not conceived as a short term "study and report" type of operation has proved to be advantageous in several respects. Over a period of years, the technical personnel can develop a considerable body of knowledge regarding the peculiar health problems, as well as the broad socioeconomic and political characteristics, of the particular country to which they are assigned. Because of the continuous operation of the *Servicio* in most countries, there is no break in the acquisition of this important background knowledge, and newly assigned technical staff may be readily oriented.

In the archives of Latin American government at all levels, as in the United States, are many studies and reports, perhaps well conceived and presented, which contain recommendations never put into effect. There are, of course, many reasons why sound recommendations never reach the execution stage, such as lack of adequate appropriations, an uninitiated legislative body, or opposition of interests within or without the government. But one outstanding reason is that the persons to whom the recommendations are directed often do not know how to go about initiating the changes suggested. It seems fair to conclude, therefore, that a large part of the success and popularity of the *Servicio* has been due to the fact that in actual operation it has provided dramatic demonstrations and has developed impact programs instead of making recommendations and leaving them to inexperienced, and to a large extent untrained, officials to carry out.

Characteristics of a locality often require the adaptation of tried methods—physical, social, economic, or political. Too often the technician in a survey-and-report operation is unable to perceive the adaptations necessary, with the result that the entire report is jeopardized in the minds of the local persons to whom it is directed.

In contrast, the *Servicio* operation allows the technician to make his "report" in the form of an actual demonstration project, with regional characteristics taken into account and with the collaboration of the national officials. Thus, the technician may adapt his acquired skills

and knowledges as operations dictate and submit a "final report" in the form of an operating service. Moreover, the nationals who have participated in the planning and execution of such a project are familiar with the project's goals and with its technical operation.

Training of Nationals

An important part of any technical assistance program is the providing of scholarships and travel grants for study in foreign countries. The *Servicios* utilize this practice with a high degree of success. As part of the host government, the *Servicio* is in position to evaluate the qualifications of applicants for such training. Equally as important, *Servicio* personnel are in a position to appraise in advance the opportunities that the national, once trained, will have to utilize his training in the services of his country. The *Servicio* itself provides an operating program to which many trainees return for the first application of their newly acquired skills.

In addition to contributing to the formal training program, the *Servicio* provides an opportunity for inservice training of Latin Americans. For example, when *Servicios* were established in many countries, few if any Latin American sanitary engineers were available. The *Servicio*, therefore, employed civil engineers or persons with engineering training or experience. They were given work assignments under the supervision of the field party's sanitary engineers in the design and construction of water supply and sewerage systems and on malaria control and other public health engineering projects. Thus, they received specialized training during the course of their work. The *Servicio*, by the nature of its structure and function, makes this type of training an effective contribution to the cooperative program.

A Base for Indirect Assistance

Whether a *Servicio* program is carried out as a demonstration project or as an impact program, actual operations and administrative direction rests within the *Servicio*. Therefore, technicians serving in a consultative capacity to

another ministry or unit of government may be assigned to the *Servicio* field party. By having the *Servicio* as a base of operations, such a consultant operates in a preferential setting as compared with the consultant having no previously established base of operation and lacking the official status of the *Servicio* personnel.

Since the *Servicio* functions as a part of the government of the host country and is closely associated with the operations of other branches of that government, the technicians of the *Servicio* are in a good position to judge where grants-in-aid may be made effectively. Certainly, it would appear that where the grant-in-aid is used in a technical assistance program, the guidance of on-the-spot field party personnel would be imperative.

The *Servicio*, by reason of its unusual freedom of action, is in a position to make studies and conduct research programs either as a part of its own program planning or as aid to other units of government. Such research has the advantage of intimate knowledge of the relevant factors within the country and of close cooperation between the *Servicio* and other governmental and private agencies in the country.

A Stable Base

The relative instability and frequent change of governments in some Latin American countries constitute a factor which has demanded serious consideration by both government and private industry in their relationships with these countries. The *Servicios* have proved to be a stable base of operations for the technical assistance program, subject to minimum effect by political change in the host country.

The written basic contract under which the *Servicio* operates, with its great prestige as an international agreement, has been honored without exception by all governments, whether they have come to power by election or otherwise. When there is a change in government or a change in the ministry of health, which in some countries is quite frequent, the previously agreed upon technical cooperation program continues until the new government or the new minister becomes sufficiently oriented

to plan new projects with the chief of field party. It is true that in some instances a new minister may change the emphasis of a program, but observation has led to the conclusion that changes in the chief of party have had more apparent effect upon changing the emphasis of the cooperative program than have changes in the host government. The popularity of the *Servicios*' programs have often led to the indorsement of their activities by all political factions, or at least to the elimination of their activities from discussion in political campaigns.

Training in General Administration

The opportunity which exists in the *Servicio* for the training of nationals in many aspects of general administration is one of the strong positive factors in favor of the type of administrative arrangement it represents.

Experience has clearly demonstrated that successful development of a health program cannot be accomplished by the development of skills in the field of medicine and engineering alone. Basic principles of general administration must be developed in any government before highly technical skills in such fields as health, education, or agriculture can attain the desired ends. The *Servicio* as an operating agency under the direction of, or greatly influenced by, the chief of field party offers an excellent base for demonstrating techniques in personnel administration, financial administration, procurement, and control of property, and orderly office management. Through the business manager and other members of the field party it should be possible to assist the ministries to improve their practices in these fields. This would go a long way toward assuring continued operation of *Servicio* programs at a reasonable level of competence after they are turned over to the ministries.

Problems of Responsible Administration

It is a generally recognized principle of administration that divided authority and responsibility for the operation of a program usually lead to confusion, irresponsibility, and

failure to achieve the desired results. The cooperative program by its very nature implies that the ultimate responsibility and authority for it rest with two sovereign governments. This problem has been met primarily by the delegation of authority and responsibility for program planning and operation in each country to the chiefs of field party in that country. The host governments agreed to the designation of the chiefs of field party as the directors of the *Servicios*, and in practice they have delegated practically complete operational responsibility to them. Thus, the chief of field party of each *Servicio* may put a program into action when he obtains the concurrence of the minister of health on specific projects, so long as it falls within the general framework of the bilateral agreement. Although project agreements do not require prior approval by the Institute, they are reviewed by it for form and legal commitments which may be involved.

The mere delegation of authority to the chiefs of field party does not completely solve the problem of dual responsibility, although it has unquestionably done much to facilitate operations.

The chief of field party has considerable prestige in most of the Latin American countries. He is an official representative of the United States Government. In some cases his salary is higher than that of the highest paid national government official. He has a considerable budget at his disposal, with few of the checks and controls imposed upon other operating officials in either country. In some countries, because the *Servicio* has demonstrated comparatively high efficiency, it has been asked to assume the role of purchasing and importing agent for other sections of the host government. This activity requires the handling of considerable sums of money in addition to the *Servicio* funds and not subject to the same control and audit as are the *Servicio* funds.

All these factors make it clearly impractical for the Institute to delegate completely its responsibility for the *Servicio*'s operations and necessitate a bifurcated administration by the two governments involved. They also emphasize the absolute necessity of having outstanding administrators as chiefs of field party.

Inherent in the administration of the *Ser-*

vicios is the danger that they will develop into governmental institutions interested in self-perpetuation and lose sight of the fact that their existence is solely for the purpose of assisting a national government in strengthening existing units of government or in developing new units, all of which are to be fitted eventually into a unified and harmonious national governmental operation in a particular field of endeavor. Since the *Servicio* operates in a pref-

erential setting, it is much easier for it to develop and maintain specific health services at a high level of efficiency than it is for most units of a national government. Because of an understandable pride of accomplishment and a reluctance to see the developed services undergo any unfavorable change, there has been a tendency to continue the programs and facilities under the auspices of the *Servicio* for longer periods than would appear to be desirable.

In considering the advantages and disadvantages of the Servicio as an administrative device, the evaluators reached the conclusion that, although full use has not been made of its positive administrative potential, not many of the negative possibilities have materialized to an extent to cause serious concern regarding the technique. They agreed that over a period of

years the Servicio has worked, and worked well, and that the programs undertaken through this type of organization have been unquestionably highly successful. They concurred in the view that certainly no other type of administrative organization has been as thoroughly tested over such a period of time and in such a setting and found to be so successful.

United Nations Day

October 24 has been designated as United Nations Day by Presidential proclamation.

President Eisenhower urged the citizens of the Nation to observe the day by "sending messages to friends, relatives, and associates in other member countries of the United Nations, by learning more about the United Nations and its members, and by expressing their confidence in the United Nations, their friendship for other peoples, and their faith in the ultimate triumph of peace and justice through the efforts of men of good will."

He also called upon "officials of the Federal, State, and local governments, the United States Committee for United Nations Day, representatives of civic, educational, and religious organizations, agencies of the press, radio, television, motion pictures, and other communications media, and all citizens to cooperate in appropriate observance of this day throughout the country."

The proclamation pointed out that the United Nations provides the peoples of the world with an organization through which international differences in the economic and political fields can be peacefully resolved; that the need for the United Nations is greater than ever before, and that its success depends on the extent to which its members give it support.

1952 Provisional Data Indicates Decline In Tuberculosis Mortality

In 1952 in the continental United States, there were an estimated 25,080 tuberculosis deaths, or 16.1 per 100,000 population, according to 10-percent sample tabulations by the National Office of Vital Statistics. State health department provisional tabulations are usually slightly lower and in 1952, as reported to the Division of Chronic Disease and Tuberculosis on the Annual Tuberculosis Report, give a total of 24,195 deaths, a rate of 15.5.

Prepared by the Division of Chronic Disease and Tuberculosis, Public Health Service.

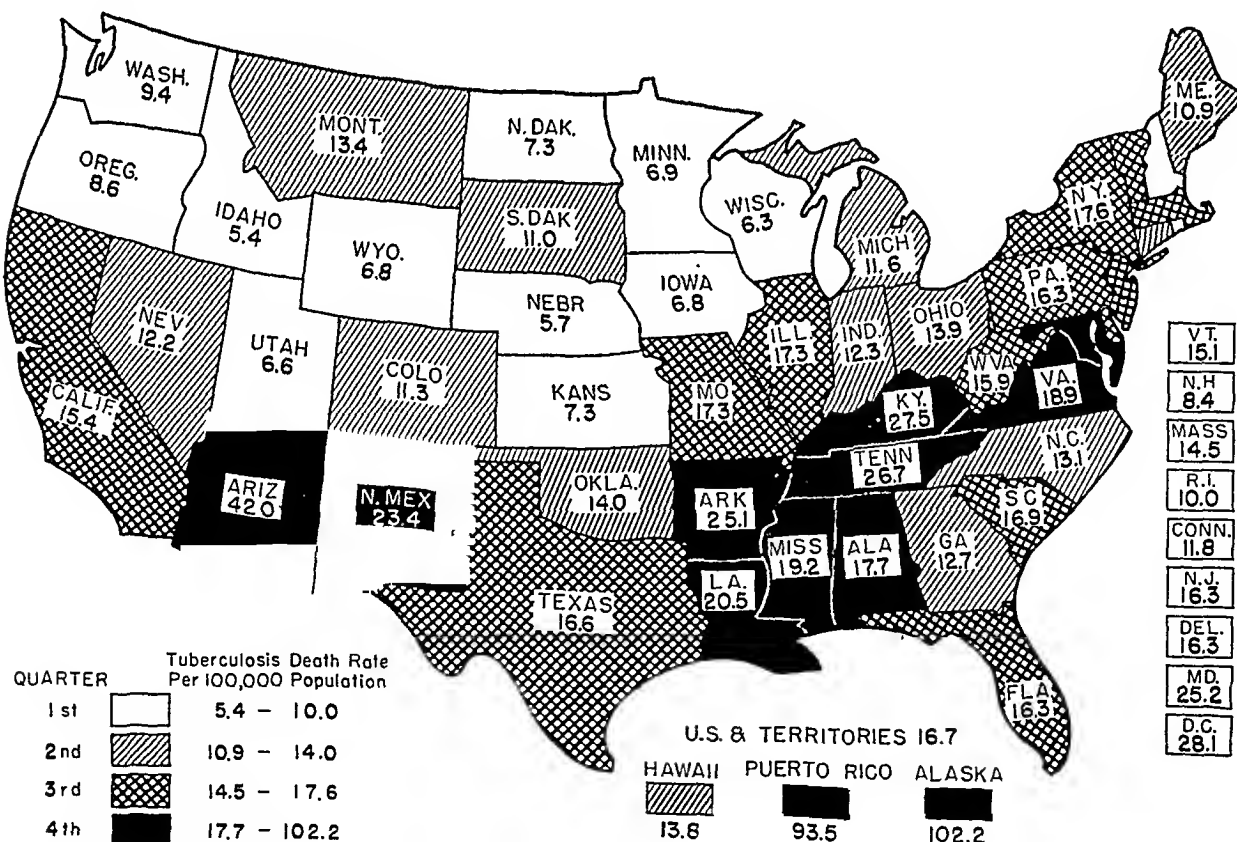

Thus, these two provisional figures, while not identical, are in agreement that there was a decline of approximately 30 percent in the tuberculosis death rate from 1950 to 1952.

Even though tuberculosis mortality is not by itself a realistic measure of the extent of the problem, it is still of general concern and serves to illustrate the progress made in an important aspect of tuberculosis control.

Twelve States had tuberculosis death rates in 1952 of less than 10, while 7 States, the District of Columbia, Puerto Rico, and Alaska had rates in excess of 20 (see map).

The cities with a population of 100,000 and over as a group had a provisional tuberculosis death rate of 22.4, or more than 70 percent higher than the death rate for the remainder of the country. (This does not include 6 States for which rates for their larger cities are not yet available.) Higher death rates in some of the States are partly due to the presence of highly urbanized areas.

Tuberculosis death rates in the United States and Territories, 1952, provisional data.

Source: Annual Tuberculosis Reports (PHS - 1393 Rev. 1-52)

New York State, exclusive of cities of 100,000 population and over, has a tuberculosis death rate of only 10.7. Michigan, exclusive of the large cities, had a rate of 7.7, and Minnesota, exclusive of the large cities, had a rate of 5.1 per 100,000 population in 1952. However, even with the low rates which result when the cities over 100,000 population are removed

from consideration, there were in the remainder of the continental United States in 1952 more than 13,000 tuberculosis deaths.

Tremendous progress has been made in the reduction of the tuberculosis death rate. It is hoped that within the next few years similar progress can be made in reducing the number of new tuberculosis cases.

To the Professional Public Health Worker

You, like the specialist in medical and other fields of science, know how important it is to be informed on current knowledge in your specialty. And, for the most part, you rely on the first-hand availability of the leading journals and periodicals in your specialty.

But as more becomes known of public health practice and research, the more complex this science becomes. There comes too the need to relate the activities of all its component disciplines—the members of the family of public health—one to the other, and each to the whole. And for each specialist there is a need to read regularly the journals devoted to unifying the family of public health. *Public Health Reports* is such a journal.

Milk Sanitation Honor Roll for 1951-53

Seventy communities have been added to the Public Health Service milk sanitation "honor roll" and 42 communities on the previous list have been dropped. This revision covers the period from July 1, 1951, to June 30, 1953, and includes a total of 261 cities and 62 counties.

Communities on the "honor roll" have complied substantially with the various items of sanitation contained in the Milk Ordinance and Code recommended by the United States Public Health Service. The State milk sanitation authorities concerned report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk is sold.

The recommended milk ordinance, on which the milk sanitation ratings are based, is now in effect through voluntary adoption in 400 counties and 1,558 municipalities. The ordinance also serves as the basis for the regulations of 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated in the recommended ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage

This compilation is from the Division of Sanitation of the Bureau of State Services, Public Health Service. The previous listing was published in Public Health Reports, April 1953, pp. 445-448. The rating method was described in Public Health Reports 53: 1386 (1938), Reprint No. 1970.

communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

The rules for inclusion of a community on the "honor roll" are:

1. All ratings must be determined by the State milk sanitation authority in accordance with the Public Health Service rating method, which is based upon the grade A pasteurized milk and the grade A raw milk requirements of the Public Health Service milk ordinance. (A departure from the method described consists of computing the pasteurized milk rating by weighting the pasteurization plant rating twice that of the raw milk intended for pasteurization.)

2. No community will be included

in the list unless both its pasteurized milk and its retail raw milk ratings are 90 percent or more. Communities in which only raw milk is sold will be included if the retail raw milk rating is 90 percent or more.

3. The rating used will be the latest submitted to the Public Health Service, but no rating will be used which is more than 2 years old. (In order to promote continuous rigid enforcement rather than occasional "clean-up campaigns," it is suggested that when the rating of a community on the list falls below 90 percent, no resurvey be made for at least 6 months. This will result in the removal of the community from the subsequent semiannual list.)

4. No community will be included on the list whose milk supply is not under an established program of official routine inspection and laboratory control provided by itself, the county, a milk control district, or the State. (In the absence of such an official program there can be no assurance that only milk from sources rating 90 percent or more will be used continuously.)

5. The Public Health Service will make occasional check surveys of cities for which ratings of 90 percent or more have been reported by the State. (If the check rating is less than 90 percent, but not less than 85, the city will be removed from the 90-percent list after 6 months unless a resurvey submitted by the State during this probationary period shows a rating of 90 percent or more. If the check rating is less than 85 percent, the city will be removed from the list immediately. If the check rating is 90 percent or more, the city will be retained on the list for 2 years from the date of the check survey, unless a subsequent rating during this period warrants its removal.)

New York State, exclusive of cities of 100,000 population and over, has a tuberculosis death rate of only 10.7. Michigan, exclusive of the large cities, had a rate of 7.7, and Minnesota, exclusive of the large cities, had a rate of 5.1 per 100,000 population in 1952. However, even with the low rates which result when the cities over 100,000 population are removed

from consideration, there were in the remainder of the continental United States in 1952 more than 13,000 tuberculosis deaths.

Tremendous progress has been made in the reduction of the tuberculosis death rate. It is hoped that within the next few years similar progress can be made in reducing the number of new tuberculosis cases.

NOTE: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90-percent or more compli-

ance with the grade A raw milk requirements of the Milk Ordinance and Code recommended by the United States Public Health Service.

Note particularly the percentage of the milk pasteurized in the va-

rious communities listed. This percentage is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized, either commercially or at home, before it is consumed.

The Genera of the Homobasidiomycetes

U. S. Department of Agriculture, Division of Mycology and Disease Survey, Special Publication No. 3. 1953. By William Bridge Cooke. Limited edition, available on request to the Bureau of Plant Industry, Beltsville, Md. 100 pages.

This current listing of the genera of higher fungi gives 1,521 generic names of the polypores and overlapping groups and is intended as a reference for persons working with the higher fungi. Listed are the wood rotting fungi, such as dry rot; mushrooms and toadstools, including soil fungi and mycorrhiza formers whose fruit bodies may be poisonous or edible; and some plant pathogens. The compilation, arranged alphabetically, brings together for the first time widely scattered information found in private files, in technical publications, in published reviews, and in other relatively inaccessible places. The gastromycetes are not included in the compilation.

William Bridge Cooke is the compiler of the list. He is now a mycologist with the Environmental Health Center of the Public Health Service at Cincinnati and formerly a research associate in mycology at the State College of Washington, Pullman, Wash.

Individual Water Supply Systems

Public Health Service Publication No. 24. Revised 1950. Reissued 1953. 61 pages; illustrated. 25 cents.

Because of the accelerated rate of housing construction and the subsequently aggravated environmental health problems, especially in rural communities, the Joint Committee on Rural Sanitation has prepared these recommendations to establish a uni-

form approach for various Federal agencies concerned with the sanitation of individual water supplies.

Limited to the sanitation aspects of small water supplies used by one or possibly several families and by rural schools, recreational areas, and camps, the recommendations are applicable to newly developed supplies, alterations or extensions to existing supplies to eliminate sanitary defects, and maintenance of special vigilance on all questionable conditions until adequate corrections have been made.

The recommendations cover basic requirements, water-supply development of ground waters and surface waters, water purification, and pumping, distribution, and storage. Appendixes include recommended procedures for cement grouting of wells and for disinfection of wells. A bibliography on individual water supply systems is also given.

Typical Architectural Program for a General Hospital

Public Health Service Publication No. 322. 1953. 23 pages. A limited number of individual copies are available on request to the Division of Hospital Facilities, Public Health Service, Washington 25, D. C.

This publication is intended to serve as a guide in the development of architectural programs for the design and construction of hospital buildings. Such programs should be prepared through the cooperative efforts of the hospital board, administrator and staff, hospital consultant, and others concerned, and contain, in reasonable detail, the information which is vital to the architect before starting the drawings.

By presenting the type of information required in a usable format, this

pamphlet will, it is hoped, stimulate the preparation of adequate architectural programs, the scarcity of which has proved to be a considerable handicap to good hospital planning.

Outpatient Departments For 50-, 100-, and 200-Bed General Hospitals

Public Health Service Publication No. 318. 1953. 14 pages; illustrated. Available on request to the Division of Hospital Facilities, Public Health Service, Washington 25, D. C.

This brochure is a compilation of material from Elements of the General Hospital and other publications of the Division of Hospital Facilities. It is intended to serve as a ready reference until more detailed studies relating to outpatient facilities are completed.

The brochure describes the requirements and functional design relationships of the various component sections of the outpatient department of the 50-, 100-, and 200-bed general hospital. Floor plans and discussion regarding waiting-room areas, information, appointment, medical records, social service, examination and treatment rooms, drug dispensary, and a dental suite are presented.

The Child With a Cleft Palate

Children's Bureau Folder No. 37. 1953. 13 pages; illustrated. 10 cents.

One baby in every 1,000 is born with a cleft palate. That baby now has a better chance of overcoming this handicap than has been true in the past because of increased understanding of the problem and better means and increased skill in the treatment of the cleft palate.

This Children's Bureau publication, another in a series of pamphlets designed to help parents who have a child with a handicapping condition, outlines different ways of

treating cleft palate, tells what special care is needed, underlines the importance of early speech training, and tells where parents can go for help in their community.

Emphasis is placed on the fact that cleft palate is not a hopeless handicap and that thousands of men and women born with a cleft palate have become business leaders or hold responsible, well-paying professional jobs. With understanding and proper guidance any child with a cleft palate has every chance to develop into a useful, happy, and successful adult.

Health Status and Services, January 1952. Economic Base Study, Arkansas-White-Red River Basins

Public Health Service Publication No. 313. Health, Housing, Education and Recreation Series, part VI, section 1. 1953. By Rollo H. Britten and Maryland Y. Pennell. 101 pages; tables, maps. Available on request to the Division of Engineering Resources, Public Health Service, Washington 25, D. C.

Authorized by the Flood Control Act of 1950, the Arkansas-White-Red River Basin Interagency Committee determined that a comprehensive economic base survey should be made to serve as a guide for the future development of this river basin area. Intended to establish the developed and undeveloped natural resources in the area, the survey is divided into 10 parts: population; labor force and employment; income; chief patterns of economic activity; natural resources; health, housing, education, and recreation; opportunities for development; economic history of the area; special reports series; and future economic development and programs for achievement. Various Federal agencies were assigned to

prepare the several parts of the report, the Department of Health, Education, and Welfare being responsible for the survey of health, housing, and recreation.

This publication contains statistics on the sickness and mortality rates, and the adequacy of medical and related services and facilities for the eight State sections and for various geographic subdivisions of the area included in the Arkansas-White-Red River Basin. The survey reveals that mortality rates from all causes are the highest for the New Mexico and Louisiana State sections and lowest for Kansas, the Texas Panhandle, and western Oklahoma. Mortality rates for tuberculosis are highest for Arkansas, Missouri, and New Mexico. The basin presents a few areas of high infant mortality, especially in the New Mexico and Colorado State section; maternal mortality rates are high in Arkansas, Louisiana, New Mexico, and eastern Oklahoma. The areas of greatest incidence of typhoid fever are mostly in the eastern and southern parts of the basin.

Health manpower is at a low level in the basin. It is about two-thirds that of the country as a whole for each of four types of personnel—physicians, dentists, nurses, and sanitary engineers. The number of general hospital beds in relation to the population is less in this area than in the country as a whole—2.9 per 1,000 persons in the basin, 3.6 in the United States. Only half of the counties have full-time local health units, but 72 percent of the basin population is served.

In terms of healthfulness of the area and the facilities available for the maintenance of health, as discussed in the report, the outstanding areas of the basin are Kansas, the Texas Panhandle, Colorado, and the western and central parts of Oklahoma.

Handbook on Sanitation of Vessel Watering Points

Public Health Service Publication No. 274. 1953. 12 pages; illustrated. Available on request to the Division of Sanitation, Public Health Service, Washington 25, D. C.

Important in the health protection of passengers and crew members aboard vessels is the provision of safe water for drinking and culinary purposes. This handbook is intended to serve as a guide for those who are charged with the design, construction, or operation of facilities on wharves and piers for loading potable water on vessels, and for the personnel of the Public Health Service and State and local agencies concerned with the supervision of vessel-watering points.

The standards set forth in this handbook are concerned with the protection of water during the course of delivery from an approved source to the filling connections of the vessel's potable-water storage tank. They cover the water-distribution system, protection against backflow from vessel to shore, protection on board ship and at the pier, hydrants, watering hoses, appurtenances, and water boats. Photographs and line drawings illustrate satisfactory installation of watering facilities.

The handbook also includes pertinent sections of the Interstate Quarantine Regulations, a brief description of the interrelationships of vessel companies, State health departments, and the Public Health Service, relative to methods of approving water supplies and watering points. It contains a copy of the PHS form, Report on Vessel Watering Point Sanitation.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Gamma Globulin in a Poliomyelitis Outbreak In Montgomery, Alabama, 1953

By D. G. GILL, M.D., Dr.P.H.

MONTGOMERY, the capital of the State of Alabama, is located in the County of Montgomery. Together they have a population of approximately 140,000, with the city accounting for 110,000 and the rural areas accounting for the balance. A well-organized county health department serves the health needs of the combined area.

This was the setting for the first mass use of gamma globulin under the 1953 national allocation plan in an attempt to stop a threatened epidemic of poliomyelitis. Early in 1953, cases of poliomyelitis were recognized in Montgomery, but there was no indication of serious trouble until the month of June brought reports

of 55 cases to add to the 30 cases already recorded. Earlier experience in Alabama revealed that 15 percent of the cases normally occurred prior to July 1, so that the area readily met the criterion of a projected rate of 300 cases per 100,000 population by the end of the year.

Request that Montgomery and Montgomery County be permitted to use gamma globulin came from Dr. A. H. Graham, the county health officer, and his board of health, consisting of five of the leading physicians in the city. With the assurance that 250,000 cc. of gamma globulin could be made available, it was decided on Friday, June 26, 1953, to attempt the task of mass injections. Past experience in conducting mass surveys for tuberculosis and mass blood tests for syphilis led to the belief that a mass gamma globulin inoculation program could be undertaken.

It was felt that not only did the situation demand immediate action but that the program should be finished by July 4. Accordingly, the period June 30–July 3 was selected for actual injections. The combined resources of the Montgomery County Health Department and the Alabama State Health Department were merged into one unit, which functioned as such, and assignments were given to key personnel.

Calling the Alert

Some of the steps taken and the reasoning behind them are summarized as follows:

Dr. Gill, the State health officer of Alabama, took his doctorates in medicine and in public health at the University of Toronto. He joined the Alabama Department of Public Health as epidemiologist in 1925 and became director of the bureau of preventable diseases in 1928. During the war, he served as medical director of the Alabama Selective Service. In addition to holding an associate professorship in public health at the University of Alabama, Dr. Gill is chairman of the Committee of Epidemiologists, Association of State and Territorial Health Officers, and associate editor of the Journal of the Medical Association of the State of Alabama.

On p. 1025, another facet of administering gamma globulin on a mass basis is described in detail.

Flow chart of typical gamma globulin administration procedures used in Montgomery, Ala., mass inoculation program. Clinics were held in the public schools; 800 volunteer workers were recruited. **AT ENTRANCE.** 1 clerk assigns clinic numbers to families, who are asked to be seated in the school auditorium and to leave 1 seat between each family to prevent contagion. **AUDITORIUM.** 1 clerk calls families by number, in turn.

A mass meeting of physicians was called for the night of June 26. It was attended by almost every physician in the area. The response was unanimous, and the physicians agreed to work on any schedule assigned to them. It was agreed that inoculations should be performed only by physicians since the possibility of accidents and reactions could not be overlooked. Not once did the pressure of private practice prevent the complete staffing of all clinics. The furnishing of lollipops at each clinic was suggested by one physician and was carried out by the physicians themselves.

Nurses were needed in numbers at least equal to physicians. Since it was early apparent that sufficient local nurses were not available, the director of nursing for the Alabama State Department of Health was made responsible for procuring additional nurses to assist in the clinics. Fifty county health nurses from all over the State were ready for duty in Montgomery by Monday morning, June 29. Many brought their own scales since weighing was on the list of musts.

Volunteer Groups

An unknown number of volunteers were needed, and the responsibility of obtaining and assigning them to duty was a formidable task. The parent-teachers' association was requested to take on this responsibility because their organization cut across all social and economic lines and because schoolhouses were to be used as clinic points. Between Saturday morning,

June 27, and Monday morning, June 29, 600 of the eventual 800 volunteers were recruited and brought to a mass meeting at the city hall where already-appointed team captains enlisted the numbers each needed and began the assignment of work hours and particular tasks.

Throughout the mass program, all matters pertaining to volunteers were referred to the PTA organization, which saw to it that enough people were on duty at each clinic. Their members obtained lunches for the workers who were unable to leave at mealtime. They made arrangements with the police and fire departments, the sheriff's office, the transportation companies—anything that could be handled by a nonprofessional staff was done and done expeditiously.

Technical details of syringe and needle sterilization—as needed originally and as needed for re-use—were handled by the laboratory staff of the State health department. Cleaning syringes and autoclaving ran far into the nights.

Medical Corpsmen

Montgomery has two Air Force posts, at Maxwell and Gunter Air Force Bases. Because neither field could obtain globulin supplies through Service channels promptly, both were included in the overall planning. Not only did the posts do their own inoculating, but they also furnished physicians and nurses for the city clinics. Another and extremely valuable contribution was made by a large number of

REGISTRATION. 2 clerks handle details of registering children. **WEIGHING ROOM.** 4 clerks are busy: 1 weighs the child; 1 records the weight and the amount of gamma globulin dosage; 1 escorts the family to the treatment room; and 1 maintains an even flow of patients. **TREATMENT ROOM.** Of the 10-15 aides, 4-6 remove pants, 4-6 stain buttocks, and 2-3 wash syringes.

medical corpsmen who proved adept at handling the unruly few and who gave assurance to many of the timid.

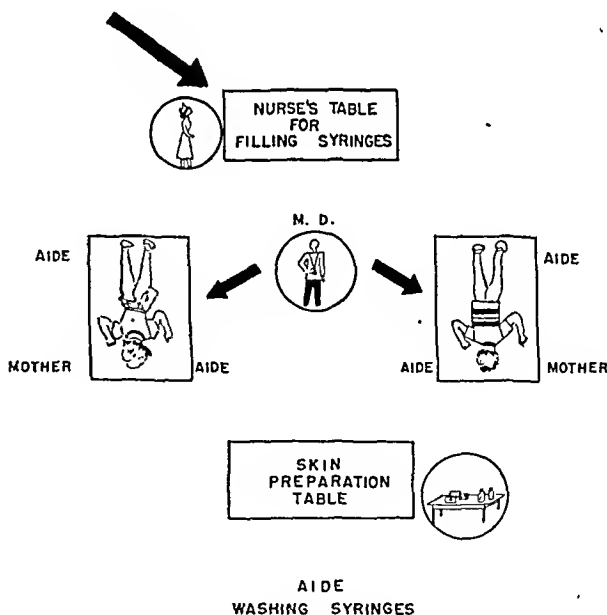

Public relations was an important consideration. Montgomery has 2 daily papers, a weekly paper, 6 radio stations, and 1 television station. In addition, the national news agencies, the newspapers from surrounding cities, national magazines and national radio, newsreel, and television companies were all intensely interested in the progress of the program. The offer of the Governor to utilize the facilities of the State's public relations bureau was gratefully accepted, and, insofar as possible, all releases were made through that agency. Montgomery citizens had been reaching a stage of severe apprehension, but the full coverage given by all agencies and the knowledge that something was being attempted served to allay hysteria and led to an intelligent support of plans.

The thousand and one details of planning clinics, procuring equipment and supplies, training personnel, and seeing that everything functioned smoothly was the task of Dr. W. H. Y. Smith, director of the bureau of preventable diseases in the State health department, and his staff of trained workers. The staff members who had been conducting X-ray surveys or blood tests applied the same techniques to handling the organization and the unification of diverse groups into a functioning whole. After the first hour, clinics operated smoothly, efficiently, and with a minimum of trouble. A

central headquarters with a battery of telephones was the nerve center of the mass inoculation program.

Almost 33,000 Inoculations

The details of actual administration were not too difficult. Twelve schools in the city and six in the county were chosen. All were open from

TREATMENT ROOM DIAGRAM. Chart shows arrangement of tables for inoculation teams, Montgomery, Ala. Usually, several physicians were on duty, each working with a separate table arrangement.

8 a. m. to 4 p. m., and a number were held open from 6 to 8 p. m. to accommodate working parents.

To avoid overcrowding it was necessary to allocate family groups to separate days. The Montgomery telephone directory, when divided into quarters, indicated that families might be similarly divided according to their surnames. Thus, all whose family names began with the letters A-F were asked to come on Tuesday, June 30, G-L the next day, M-R the third day, and the balance on the last day, Friday, July 3. Actually, of course, the first day was the heaviest, partly because some families were leaving town over the Fourth of July.

The general flow of clinic procedures and the arrangements for a treatment room are shown in the charts. In actual practice, sev-

eral physicians were frequently on duty, each with the setup shown. The arrangements for registration, weighing, and figuring the dosage of gamma globulin were sufficient, however, to prevent any delays in this part of the program.

During the 4-day period, June 30-July 3, 32,948 children, 9 years or under, received a gamma globulin dosage of 0.14 cc. per pound of body weight. Because the 1950 census had reported about 30,000 children at that time in this age group, we believe that the coverage approached 100 percent. The average dosage was about 6 cc. so that the supply of gamma globulin available was ample for this group.

The successful completion of a major undertaking on short notice is a tribute to the citizens of the community and to the staffs of the combined health departments.

Excerpta Medica Adds New Cancer Section

A new section on cancer, containing abstracts from medical journals of the world covering cancer and related fields, has been added to *Excerpta Medica*. Forming section XVI of the internationally known abstracting service, volume 1, No. 1 of the new periodical is dated July 1953.

Publication of a section devoted entirely to cancer has been under consideration for some time by editors of *Excerpta Medica*. Abstracts of all articles appearing in the international medical press concerning cancer previously were divided in the 15 sections of *Excerpta Medica*. Now this medical literature will be available to physicians in a single volume. The project was made possible through the aid of grants from the National Cancer Institute of the Public Health Service and the American Cancer Society.

The section on cancer carries 25 classifications. Abstracts of 424 articles falling into 14 of these classifications appear in the first issue. It will be published monthly and will contain 700 to 800 pages of abstracts a year. An index of authors will appear each month, and a classified subject and authors' index will appear annually.

The new publication is published in Amsterdam, as are other sections of *Excerpta Medica*, and has an editorial board composed of 32 members in addition to the two chief editors, Dr. R. van Dam and Dr. W. van Westering of the Netherlands. Twenty-two members of the editorial board are in America. Nine of the other members are divided evenly among nine western European countries, and one member is in India. National Cancer Institute members of the board include Dr. John R. Heller, director, Drs. Raymond F. Kaiser, Ross C. MacCardle, and R. R. Spencer, the last a former director of the National Cancer Institute, now retired.

Organizing Mass Gamma Globulin Clinics In Three North Carolina Counties

CHARLES M. CAMERON, Jr., M.D.

SOME 30,000 children were inoculated with gamma globulin on a mass basis in three western North Carolina counties during the period from July 6 to August 7, 1953. Inoculations were given in Caldwell County on July 6, 7, and 8, and 12,800 children were processed in the 3 days. Catawba County was the site of a 3-day inoculation program on July 15, 16, and

17, at which time 14,761 children were given gamma globulin. In Avery County, during a 2-day program on August 6-7, 3,092 children were inoculated. The pattern developed for operating the mass gamma globulin clinics in North Carolina has proved to be highly effective.

This discussion outlines the purely administrative aspects of formulating and operating a globulin mass inoculation clinic. The criteria which must be fulfilled by a county prior to receiving globulin from the Office of Defense Mobilization varied according to the amount of globulin available, and these, accordingly, are not included.

Dr. Cameron, as chief of the communicable disease control section, division of epidemiology, in the North Carolina State Board of Health, was in immediate charge of organizing the mass globulin clinics in the three North Carolina counties where poliomyelitis in epidemic form was prevalent during July and August 1953. For a report of how Montgomery, Ala., handled a threatened epidemic, see p. 1021.

After receiving his medical degree at Vanderbilt University Medical School in 1948, Dr. Cameron served as district health officer with the Tennessee State Health Department, from 1949 to 1951. During the next 2 years, he was assigned as a Public Health Service commissioned officer to the Branch of Health, Bureau of Indian Affairs. Dr. Cameron has been attending the School of Public Health, University of North Carolina, where he has completed work on his master's degree in public health.

A manual based on the operations described in this report has been distributed to all local health departments in the State.

Sequence of Events

The timetable of events in each of the three North Carolina programs broadly assumed the following sequence:

The county medical society unanimously asked the local health department to forward to the State health officer a request that the county be considered for the mass use of gamma globulin. On the basis of the age distribution of the poliomyelitis cases reported up to then, the society also set the age limits of children who would receive globulin—usually all children between birth and 10 years.

The local health officer forwarded the request and an estimate of the number of children in the selected age group. The estimate was ob-

tained from census reports, birth rates, and death rates. To determine a county's eligibility, it was necessary for the health officer to supply the following additional data to the State health officer: total number of cases with age distribution; onset of cases by day; number of deaths from poliomyelitis; ratio of paralytic cases to nonparalytic cases; and number of respirator cases.

The request was reviewed by the State health officer. Upon approval, it was telephoned to the Public Health Service in Washington, D. C., acting as the allocation agent for the Office of Defense Mobilization, which advised that globulin would be granted, how much would be available, and when it would reach the county. This information was immediately transmitted to the county health officer.

The North Carolina State Board of Health, either from the central office or directly from the field, contacted the New York office of the National Foundation for Infantile Paralysis and informed it of the gamma globulin grant to the county and the estimated number of children to be inoculated so that a sufficient supply of needles and syringes could be sent. The Foundation shipped by air express directly to the county these and the other supplies it provided.

The globulin was shipped directly by air from the manufacturer to the county health officer.

The local health officer then had the responsibility for determining the number and schedule of clinics necessary to cover his county. To do so, he considered the availability of physical facilities such as schools for suitable clinic sites; the population distribution within the county; routes of transportation and communication, and the general availability of transportation; and the number of local physicians, nurses, and nurses' aides available to staff the clinics.

At this point, the following necessary efforts were carried out simultaneously. The State board of health was requested to recruit any additional physicians and nurses who might be needed to staff the clinics. The organization for local lay workers was set up, and the recruiting of the volunteers was started. The supply and equipment items to be obtained locally were

listed (see minimum list), and procurement was begun. Public relations outlets such as press and radio were alerted, and arrangements were made for the regular release of pertinent information, particularly within the county.

Once clinic sites were agreed upon, it was necessary to see that tables and other fixtures were available and that water, lights, refrigeration, and telephones were in operating condition.

Two nights before the opening of the clinics, a mass meeting of all volunteer workers was held at the clinic at which they would serve. At that time, job assignments were made, and the techniques of clinic operation were outlined. The National Foundation for Infantile Paralysis assisted in the orientation of lay volunteers by showing the movie "Marbles and Lollipops."

On the day before the beginning of the clinic operation, supplies were moved to the clinics from the central supply depot. The gamma globulin, however, was kept under refrigeration until the day the clinic opened. Globulin must be stored and maintained at 40°-50° F., and appropriate storage facilities in the county had to be obtained.

As they were recruited, local professional personnel were assigned to the respective clinics. As the outside professional personnel arrived, they were assigned living quarters by the health department staff member in charge of housing professional workers. They also were assigned to work in the respective clinics as they arrived. Arrangements for transportation to the clinic sites were completed with the motor pool.

Administration and Operations

The county health department was the official agency in charge of all operations within the county. The local health officer of the respective counties was in charge of the entire mass inoculation operation within the county. He worked directly under the supervision of the local board of health and was assisted by a poliomyelitis committee of the local medical society and by the chief of the communicable disease control section of the North Carolina State Board of Health's division of epidemiology. With the aid of his staff and consult-

ants, he made the decisions as to the sites, scheduling, and operation of the clinics.

The recruitment and scheduling of local professional personnel in two counties was handled directly by the health officer or by a health department staff member; in another, they were the responsibility of a member of the poliomyelitis committee of the local medical society. Both systems worked equally well. The recruitment of additional professional workers from outside the county was handled in every instance by the State board of health; and the housing and scheduling of these workers was handled by the local health department staff. The sched-

uling and handling of lay workers was delegated to a lay chairman and his associates.

Because of the complexity of the organizational and operational setup of the mass inoculation program, the entire time of the local health officer and of the State consultant was required to keep the clinic program operating smoothly. When actual operations began, 1 of these 2 individuals remained on duty at the command post at all times. The other circulated from clinic to clinic, generally supervising field operations.

Keeping the distribution and flow of supplies continuous was a difficulty. Because the ratio

Minimum equipment and supplies for each gamma globulin clinic, North Carolina, 1953

Equipment	Supplies	Supplies—Continued
14 30" x 5' x 6' cafeteria-size tables.	Syringes $\frac{3}{4}$ 10 cc.; $\frac{1}{4}$ 5 cc. (at least 500 total). ¹	12 lead pencils.

of children to the supply of syringes was high, it was necessary to clean, pack, and re-autoclave syringes while the operation was in progress. Local hospitals did all the autoclaving without charge. A supply depot was created at the local health department in each county. Supply transport corps were set up in two counties by the National Guard and in the third by volunteer workers.

In every county, communications between the clinic and the health center were maintained by telephone and by short-wave radio. The radio eliminated the overtaxing of telephone facilities at the health center. Radio sets and operators were volunteered by National Guard units and by other groups, and their location in the clinics and health centers greatly facilitated communications. This procedure is recommended for any operation of this type.

School lunchrooms were selected as the most suitable clinic sites. School authorities were most cooperative in making all facilities available. Usually, schools are located in centers of population, are easily reached by road, and parents were therefore asked to go to the clinic in the school nearest their home.

It was not considered feasible to attempt to assign the residents within certain geographic areas to any particular clinic, nor did it appear necessary to attempt to take various segments of the population on an alphabetical basis, chiefly because the amounts of globulin available were limited, and the supply was usually exhausted before the end of the scheduled operations.

Role of the State Board

In every county the program was recognized as one of local origin and as a local responsibility. The role of the State board of health in the clinics varied slightly from county to county. Briefly, the board:

Assisted the local health officer in the administration of the program.

Through the communicable disease control section of the division of epidemiology, supplied consultation to the local health officer in the organization, planning, and staging of the clinic.

Detailed a field epidemiologist to assist the

health officer in the investigation, collection, and tabulation of epidemiological data relative to the poliomyelitis outbreak.

Recruited professional personnel, both physicians and nurses, from other local health departments and medical centers in the State.

Served as the official channel of communication with the Office of Defense Mobilization, the Public Health Service, and the National Foundation for Infantile Paralysis.

Through the public relations officer in the Raleigh office, assisted in the release of public information about the incidence of poliomyelitis and the gamma globulin program.

Provided plans, program, and personnel for the evaluation of the possible effect of gamma globulin on the incidence of poliomyelitis; on the administrative aspects of staging a mass inoculation clinic; and on the allocation and distribution of gamma globulin.

Clinic Organization

A basic clinic unit was set up for all North Carolina clinics. Each unit consisted of a professional group and a lay group. The organization of each lay group was planned so that it was possible to process patients for one or more groups of professional workers. In smaller operations, the clinic staff was composed of 1 professional group and 1 lay group. In the larger operations, as in Catawba County, each lay group served 2 or 3 professional groups with ease.

Professional Personnel

All inoculations were given by physicians to avoid any criticism which might have resulted from any immediate or delayed untoward reaction to the injections. The basic professional operational unit was composed of 2 physicians, 1 public health nurse in charge, 5 registered nurses, and 4 nurses' aides.

At times, the nurses performed the aides' duties and also rotated jobs with the other nurses in the clinic. Four of the registered nurses checked the dose of globulin, which had been calculated at the weighing table, and filled the syringe with the correct amount. One registered nurse was assigned as a relief nurse to

circulate in each clinic and to supervise the cleaning and packing of syringes and the distribution of other supplies.

The aides' duties consisted of carrying the filled syringe to the injection table without contamination and assisting the physician by cleansing the skin.

A local public health nurse was assigned to each clinic and designated as the professional worker in charge of the entire operation. It was her responsibility to see that each worker performed his prescribed tasks, that supplies were sufficient, and that the clinic operated at maximum efficiency at all times.

Local physicians worked only 4-hour shifts because of their immediate responsibilities in the community. Physicians recruited from outside sources worked 8-hour shifts. The majority of nurses and nurses' aides in the local community were also used on 4-hour shifts, but nurses recruited from other county health departments or elsewhere usually worked at least 8 hours a day. The public health nurse in charge was on duty throughout the hours of clinic operation, either 10 or 12 hours, with only short periods of relief.

The assistance of all professional workers—physicians, nurses, nurses' aides—who were county residents was enlisted. At no time was there a sufficient number of professional workers present in the county to meet the staffing requirements of the program.

In the recruiting of additional personnel, the North Carolina State Board of Health played a key role in the staging of the globulin clinics. Working through its division of epidemiology, the State board of health contacted numerous county health departments throughout the State in the search for volunteer public health nurses who could be spared to participate in the mass inoculation programs. The response from the local health officers in making personnel available was excellent and indicative of the good neighbor policy which exists among health departments in the State.

The division of epidemiology also took the lead in contacting the three medical schools in the State in requesting that resident physicians assist in the administration of gamma globulin.

Duke University School of Medicine, the University of North Carolina School of Medi-

cine and Memorial Hospital at Chapel Hill, and the Bowman Gray Medical College and Baptist Hospital in Winston-Salem made physicians available to serve in the clinics. The globulin program would not have been possible without their assistance. In all North Carolina operations, professional workers volunteered their time.

Volunteer Workers

All volunteers needed to operate globulin clinics were recruited from the community in which the operation was staged. Persons under 16, pregnant women, and anyone suffering from acute or chronic communicable diseases were excluded from the volunteer ranks. All the workers served without reimbursement directly under the supervision of the chairman for each clinic.

The health officer named an overall chairman in each county to head the volunteer lay workers. He, in turn, named a chairman for each of the proposed clinics. The latter was responsible for recruiting and assigning volunteer workers to the various clinic shifts.

Often, these chairmen recruited the entire membership of various community clubs and organizations to serve on a given shift in the clinics. In the instance of a clinic scheduled to operate in the same site for more than 1 day, the same group was asked to work the same shift each day in order to reduce the confusion and time lost in reorienting lay workers.

The usual shift of duty for the lay volunteers was from 5 to 6 hours a day, since this group assisted prior to the daily opening of the clinic in distributing supplies and materials and remained for clearing up after the clinic closed.

A minimum of 40 volunteers was needed for each shift in each basic clinic unit. However, the single basic lay unit was able to handle the patient load for as many as 6 or 8 physicians and the corresponding number of nurses and aides. This was accomplished by adding one guide for each injection table added to the clinic.

In addition to the chairman of each volunteer unit, the basic minimum of 40 to a shift consisted of 2 hostesses, 10 guides, 2 clerks at the registration table, 2 weighers at the weighing

table, 2 clerks at the weighing table, 2 lifters (male) to pick the children up from the injection tables, 2 workers at the first syringe wash table, 4 workers at the second syringe wash table, 4 workers for the syringe drying, wrapping, and packing detail, 2 janitors, 2 policemen or others for directing traffic, 2 workers for distributing candy and other treats to the children, 1 worker to distribute poliomyelitis leaflets, 1 telephone operator, 1 telephone messenger, and 1 radio messenger.

Transportation Corps

The transportation corps was an integral part of the lay organization. It was responsible for transporting to and from the clinics any parents and children when they did not have the means of reaching the clinic; professional personnel, particularly those recruited from outside the county who lacked transportation or who were unfamiliar with the county; and lay volunteers when they had no means of reaching the clinic.

Organization and operation of the transportation corps was successfully delegated to a local club or organization, which called on automobile dealers, taxi companies, and other groups to supply automobiles and drivers.

Motor pool headquarters were set up away from the health center to reduce traffic and tele-

phone calls into the center, which usually served as a nerve center for the entire operation. The telephone number of the motor pool was widely circulated in the county.

The trucks, jeeps, and other vehicles needed to transport supplies and other materials to and from the clinic sites made up a separate unit of the motor pool. This supply transport unit usually functioned directly under the health department staff.

Public Information

Informing residents of the county about the details of the inoculative program schedule was not a problem in those counties with local radio stations and local daily newspapers. Avery County, however, does not have these outlets, and there the problem of informing the people was more difficult. For Avery County, then, these procedures were followed:

All telephone subscribers were called and advised of the clinic sites and schedules.

All persons on the tax rolls received a postcard giving the necessary information.

Posters and leaflets were prepared and distributed over the county.

All rural mail carriers were given the facts and were asked to spread the word along their routes.

Above: A busy registration area in a typical clinic setup. Right: A boy at the Lenoir clinic gets his shot of gamma globulin. The physician inoculates; the aide holds the child; and the male volunteer, a local fireman, stands by to lift the child from the table.

All ministers were asked to tell their congregations about the clinics.

The cooperation of two local political organizations representing the Democratic and Republican national parties was enlisted. They agreed to spread the word from house to house in the more isolated areas.

All volunteer clinic workers who attended the mass meeting 2 nights before the start of the program were asked to carry the word to their respective communities.

Newspapers from outside areas which circulate in the county and radio stations were asked to feature the news for Avery County residents.

Relations with the press proved to be an important phase of the operation. In two counties, all press contacts were made by the local health officer. In a third county, a lay worker with a newspaper background was placed in charge of the press releases. The former method was more effective inasmuch as it is sometimes difficult for a layman to interpret and translate medical concepts and ideas as effectively as a physician. In addition, it permitted the health officer to maintain the close supervision over the content of the press releases which is not possible with the latter method.

News Releases

Press and radio releases featured these ideas:

Clinics would remain in operation at all times during the scheduled hours and would continue operating until the inoculation of all specified children had been completed or until the supply of globulin had been exhausted.

Only children who were regular residents of the county or children of transients who would remain in the county for at least 21 days would be eligible to receive the inoculations. Injections would be limited to the stipulated age groups.

Globulin would be given to noncontacts of cases only at the mass inoculation clinics. None would be available for administering in the private physician's office.

Inoculations would be given on a first-come, first-served basis. Wherever possible, parents should take children to the clinic nearest their homes.

Contacts of poliomyelitis cases should go to the family physician to receive globulin from the local health department's supply which was earmarked for administration to contacts.

Every effort would be made to avoid crowding at the clinics. Children with communicable diseases should not be brought to the clinics.

Left: A lull during the clinic procedure at the East Harper School, Caldwell County. Only 2 of the 4 injection tables are in use. **Right:** Peak of the rush period at the Harper School clinic. On the facing page at the left: Workers in the back of this cafeteria—school lunchrooms were used for gamma globulin administration in North Carolina—are wrapping syringes before autoclaving. The nurses in the foreground are filling syringes with immune serum globulin on the basis of weight-

One parent could accompany each child through the clinic.

Children should be dressed as simply as possible to facilitate undressing on the injection tables.

All inoculations would be given in the right hip.

As to the question of exceptional children or those with chronic illness, crippling, or other conditions, the parent should consult the family physician if there were any doubt as to the desirability of having the child inoculated.

Gamma globulin is harmless in most cases. However, some few children might experience headache, fever, chills, pain, or swelling about the inoculation site. If these reactions occurred, the parent should consult the family physician.

Clinic Procedures

The North Carolina clinics were scheduled to operate for either 10 or 12 hours a day. Caldwell and Catawba County clinics inoculated from 9 a. m. to 9 p. m., requiring 3 shifts of workers each day. Avery County clinics were open from 10 a. m. to 8 p. m., and 2 shifts a day were used.

A hostess met the parent and child at the entrance of the building. She assigned each child a number in the order of arrival at the clinic. The number was written on a small tag, which was pinned to the child's back so that it would be seen when the child lay on the injection table. If the group waiting was a large one, the parent was asked to wait either outside the building or in the auditorium.

When this procedure was necessary, the children were called back to the clinic, over a public address system, in groups of 20. When the waiting line was small, the parent and child were sent immediately in to the clinic. There each child was met by a guide who escorted both child and parent through the complete clinic procedure.

The first stop for parent, child, and guide in going through the clinic was at the registration desk where a 3- x 5-inch index registration card was filled in with the child's name, age, sex, and race and with the parent's name and address. (Documentary evidence of age or place of residence was not required.) The number on the child's tag was recorded on the card.

The second stop was at the weighing table where the child was weighed, and the globulin dose was calculated from a weight-dose chart. The amount was entered on the registration card.

The card was then left at the nurses' table. Next, the child was taken to the injection table, placed on it, and undressed as much as necessary.

The nurse checked the calculated dose using a weight-dose chart, filled a syringe with the correct amount, and handed both the syringe and registration card to an aide who took them to the injection table where the child had been placed. By assigning each physician four injection tables, almost no physician-time was lost in getting children on and off the tables.

The syringe was handed to the physician by the aide who then returned to the nurses' table. After the physician had inoculated the child,

dosage data. Center: Another view of a boy receiving a shot of gamma globulin. The police sergeant standing at the foot of the injection table was one of the volunteer male lifters at the Lenoir clinic. Right: Volunteer aides in the Lenoir clinic wash syringes before they are repacked and autoclaved for the next day's operation.

he handed the syringe to the guide who gave it to the worker at the first syringe wash table. The guide then helped the mother dress the child and escorted them to the exit where the child was given candy and ice cream and the mother received a leaflet, supplied by the National Foundation for Infantile Paralysis, which explained gamma globulin.

The guide then returned to the entrance to meet another parent and child.

At the first syringe wash table, the syringe and needle were flushed with washing solution, the needle was removed, and the two parts of the syringe were dismantled and fastened together with rubber bands. After the syringes were soaked for 20 minutes in a cleaning solu-

tion, they were taken to the second wash table, where they were cleaned with a bottle brush, rinsed, and placed on a clean sheet to dry. Drying was hastened by having electric fans blow over the area. When dry, syringes were not reassembled but were either wrapped in a special wrapper or in a paper towel, or they were dropped into a small envelope. They were then packed in wire baskets and returned to the hospital for autoclaving.

The programs in each of the three counties worked smoothly and efficiently, without congestion at the clinic sites, and with highest praise from parents whose children were brought to the clinics for gamma globulin administration.

Poliomyelitis Distribution In the United States, 1952

A record number of poliomyelitis cases were reported in the United States in 1952. The final figures show a total of 57,879 cases. This

Dr. C. C. Dauer, medical adviser of the National Office of Vital Statistics, Public Health Service, continues here the annual report series on poliomyelitis in the United States.

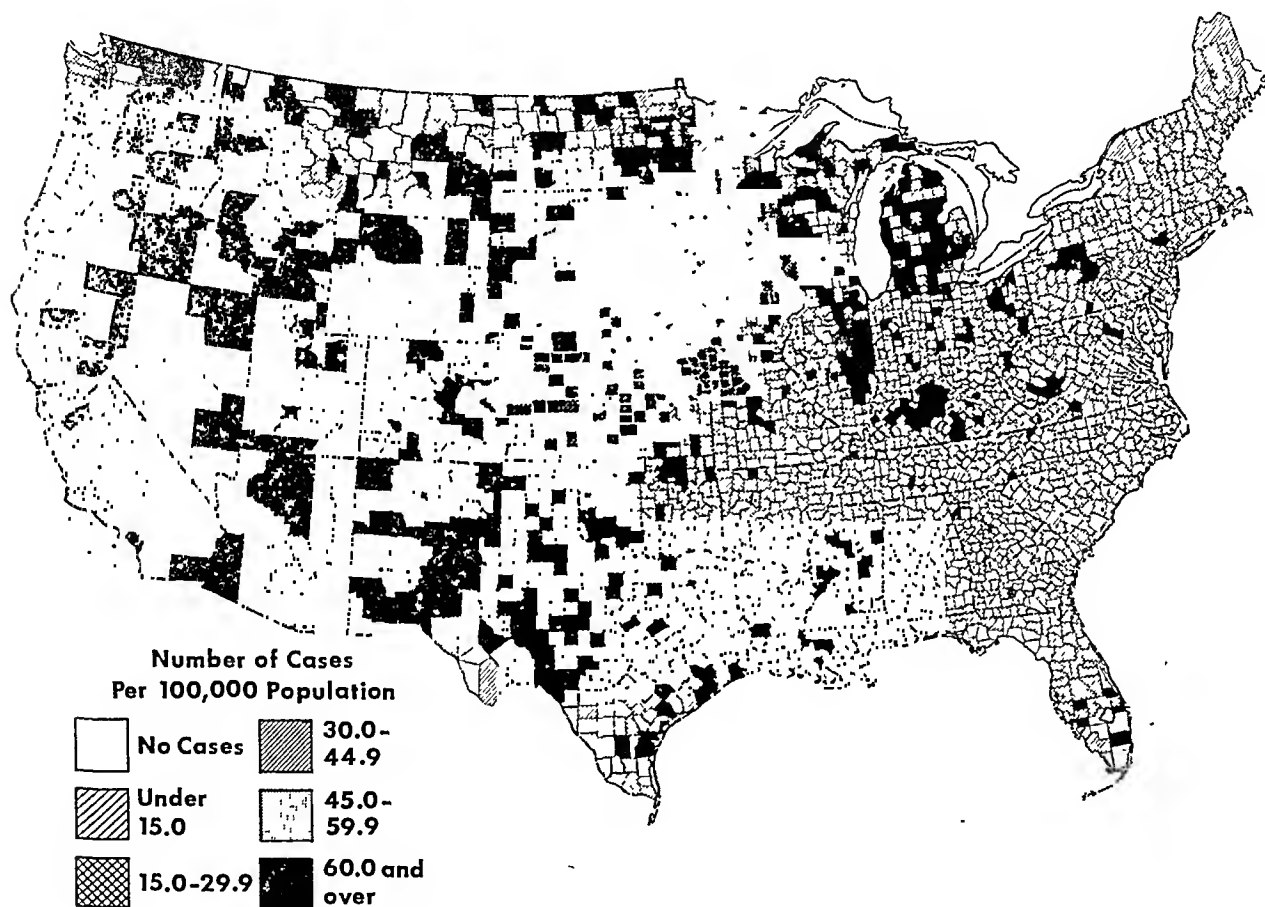

total is almost 38 percent higher than the previous high year of 1949, when a total of 42,033 cases was reported. The incidence rate in 1952 was 37.2 cases per 100,000 population, and the estimated death rate, based on a 10-percent sample of deaths registered, was 2.1. The estimated case fatality rate for the country as a whole was approximately 5 percent. Since 1916, when the rate was about 25 percent, the case fatality of the disease has declined grad-

ually. In the decade of 1930 to 1939 it was about 13 and in the following decade it was 7.5 percent.

Although Minnesota, California, Illinois, Texas, and Michigan reported the largest number of cases in 1952, the States which had the highest incidence rates were Nebraska with a rate of 163.9 cases per 100,000 population, South Dakota with 153.2, Minnesota with 136.7, Iowa with 134.7, and Kansas with 85.8. Nine other States in various sections of the country had morbidity rates in excess of 50 per 100,000.

As shown in the accompanying map the most extensive epidemic area extended diagonally across the United States from Minnesota and Wisconsin in the north to Texas and New Mexico in the southwest. Other smaller areas of high incidence are also shown.

About 37 percent of the total number of cases reported were classified as paralytic and 22 percent as nonparalytic. The status of the remaining 41 percent is unknown and is designated as unspecified.

Distribution of poliomyelitis in the United States, by county, 1952. This map is the 20th of the series showing distribution by counties in the continental United States. The first report appeared in Public Health Reports in 1938, and covered the years 1933 to 1937, inclusive, but subsequent reports have shown the distribution for single years. The series was begun at the suggestion of the late L. L. Lumsden, who was keenly interested in the geographic distribution of diseases, particularly tuberculosis.

Case Finding Through Multiple Screening

By ARNOLD B. KURLANDER, M.D., M.P.H., and BENJAMIN E. CARROLL, M.A.

DURING the past few years, there has been a widespread interest in multiple screening—an approach to case finding characterized by the application, to apparently well populations, of a combination of screening tests for various diseases or conditions. Within a period of 4 years, multiple screening has been given extensive trial, has demonstrated its ability to find cases of disease, and has been hailed by some as an important new tool in public health work.

It is the purpose of the present paper to discuss the methods and results of some of the more extensive multiple screening projects, to consider certain principles and problems of this approach, and to stress some of their implications for the planning of screening projects.

The brief but active history of multiple screening includes at least nine major projects, ranging from pilot studies that have tested a few thousand screenees to local or Statewide operations that have screened tens, or even hundreds, of thousands of persons. Screening has been incorporated in such research studies as those planned by the Chronic Disease Research Institute in Buffalo, N. Y., and by the Commission on Chronic Illness in Baltimore, Md., and in Hunterdon County, N. J. The procedure was established on a continuing basis in Alabama and Georgia, and has been operated as an annual project in Alexandria, Va., for the past 3 years. In addition, at least 30 other

projects throughout the country have come to the attention of the Public Health Service.

Screening, using a combination of tests—although not always called “multiple screening”—has for some time been conducted by industries and labor unions. Some of this work—for instance, that done by the International Ladies Garment Workers Union—antecedates the multiple screening projects operated by health departments.

To a limited extent, multiple screening has also been introduced into hospitals. At St. Michael's Hospital in Newark, N. J., several screening tests have been given to both inpatients and outpatients, with a significant return in newly discovered cases of previously unsuspected disease. Results of a cooperative project are now being analyzed, in which the District of Columbia's General Hospital and the Public Health Service screened outpatients to study case-finding possibilities. Some proponents of the multiple-screening approach recommend that all hospitals use screening as a general preventive medicine service, giving routinely such tests as height and weight, blood pressure, urinalysis, blood counts, hemoglobin, serologic test for syphilis, chest X-ray, and electrocardiogram.

Results to Date

In the trial projects discussed above, multiple screening has shown definite promise as a way of discovering previously unrecognized disease. Nine of the major projects together have screened more than a million persons and have identified approximately 50,000 cases of disease and/or abnormalities. In all proba-

Dr. Kurlander is assistant chief of the Division of Chronic Disease and Tuberculosis, Public Health Service; Mr. Carroll, formerly a statistician in that division, is now with the National Cancer Institute.

bility, this number represents a considerable understatement of the true case finding accomplished, since complete reporting of diagnostic followup is lacking. Furthermore, some of the projects mentioned have included only 2 or 3 tests, rather than the usual battery of 10 to 12.

The project carried out through the Permanente Foundation, which screened about 4,000 longshoremen in the San Francisco Bay area, and which secured rather complete followup reports on the persons screened, discovered new cases of disease in 19 percent of the men screened. The Indianapolis, Ind., pilot study discovered new cases of disease in 10 percent of persons screened. This project, which screened an almost entirely Negro population group, applied most of the same tests that were used in the Permanente project but obtained no followup reports on abnormal weight, vision, or hearing. In Richmond, Va., 9 tests were offered to the general population and followup reports were obtained on a large number of screenees. An analysis of the total persons screened showed that about 5 percent of this total were found to have previously unknown disease.

Thus, in screening projects testing various segments of the population, 5 percent or more of those screened have been found to have significant disease that was previously unknown.

The combinations of tests used by nine major multiple screening surveys and research projects are outlined in table 1. The most commonly used tests in these projects have been chest X-ray, serologic tests for syphilis, and blood sugar determinations.

Details of the major multiple screening projects are shown in table 2, which gives a brief statement of the methods used, standards applied and results obtained. It is evident, even on casual inspection of this table, that there has been great variety on each of these points. As pointed out earlier, there was also variation in the population groups screened. Such considerations make it clear that the figures shown here should not be compared without attention to all circumstances.

Many of the available reports lack complete followup information covering the verification of screening results and the number of new cases actually discovered. Those projects using a long array of tests include those with the most complete followup studies.

It seems appropriate to consider here certain of the fundamental concepts involved in screening. Misconceptions as to basic points may lead to misapplication of methods and standards, and ultimately to the impression that the technique is without merit.

Table 1. Summary of tests used by 9 major multiple screening projects

¹³ Bausch & Lomb.
¹⁴ Not a multiple screening project.
¹⁵ Previously known cases were not screened.
¹⁶ Number of conditions.
¹⁷ No followup.

NOTE: Where no figures are given, no data were available.

Screening vs. Diagnosis

The role of screening as a brief health examination in contrast to a complete checkup has been mentioned often in the literature, but the point is worth further emphasis. The antecedents of the screening approach are to be found in many forms of examination—com-

plete and incomplete, thorough and cursory—done for purposes of employment, life insurance, selection for military service, and school health. The deliberate combination of several rapid, simple tests for such specific purposes as case finding and health education is, however, characteristic of the present concept of multiple screening.

In the nature of the two processes and in the concepts involved, fundamental differences exist between screening and diagnosis. Screening attempts only to select high-prevalence groups through the application of standardized tests to numbers of people, with full realization that there will be "errors" in the form of false positives and false negatives. Diagnosis, on the other hand, establishes or rules out disease through a synthesis of the most complete and accurate information available about a particular individual. While each of these processes is appropriate in its place, they cannot be used interchangeably.

Important differences in details of application and interpretation naturally follow because of these fundamental differences. Screen tests are applied at random to the apparently well, whereas need for the diagnostic process is indicated in the presence of symptoms or suspicion of disease. Screening is impersonal in nature, and the result of each test is measured separately by a definite standard determined in advance and generally adhered to despite the results of other tests. Even where some subjective element enters (as in examining X-ray films for evidence of pathology) the interpreter of the test results tries not to deviate from a fairly definite set of criteria. In making a diagnosis, on the other hand, the results of tests are considered in relation to other factors, and individual judgment is an important aspect of the process. If these distinctions are not kept clearly in mind in carrying out screening, confusion results.

Deficiency and Degenerative Diseases

The fact that multiple screening is used to uncover deficiency and degenerative diseases as well as diseases caused by infectious agents poses another problem which at present does not lend itself to any perfect solution. For infectious diseases we have criteria by which screening can be judged, namely, whether the infectious agent is, or is not, present, either demonstrably or in its known biological manifestations. With deficiency or degenerative diseases, however, within the limits of our present knowledge, we are dealing with variations in physiological states that may occur normally in anyone. In this kind of situation, there is

no single "correct" standard or screening level, since we are measuring values along biological gradients, with a considerable range of normality.

Along such a scale the most accurate screen test does not usually point to definite disease as contrasted to definite absence of disease. Instead, we find a gradual transition up or down a scale from relative normality to relative abnormality. We cannot expect to determine either statistically or medically an exact point where the line between normal and abnormal is to be drawn. The problem is not one of the accuracy of tests alone. The screen test measures a particular physiological state at a given point in time, but diagnostic study is necessary to relate the finding in question to other pertinent factors in order to determine whether significant disease is actually present. That is why—be the screen test ever so accurate in measuring a condition—there is a substantial percentage of suspects whose ultimate diagnosis is negative.

As the screening level is moved further and further away from the average, smaller numbers of suspects are found, but the rate of diagnostic confirmation becomes greater. Two examples that follow illustrate concretely the manner in which this occurs. The examples are taken from results of screening 857 hospital outpatients for hypertension by blood pressure determinations, and 551 such patients for diabetes by means of the Somogyi-Nelson blood sugar test at various intervals after eating (including overnight fasting). All members of both groups received diagnostic study without regard to the screening findings.

The results found in blood pressure screening are illustrated in table 3. Here it is seen that about 70 percent of the screenees had test readings below 150 mm. systolic. Above 150 the percentages of screenees found at successively higher levels decrease rapidly until only 0.6 of 1 percent had readings of 250 and above. Referring to the third column of the table, we find that at this extremely high level 100 percent of the suspects were diagnosed as hypertensive. Reading up the column, we find successively smaller percentages of established diagnoses. With a screening level of 230 mm., 100 percent of the suspects would have been confirmed as

Table 3. Percentage distribution of blood pressure readings on screening, and corresponding percentages of persons diagnosed as hypertensive¹

Systolic blood pressure reading (mm.)	Pereent of persons with indicated reading at screening	Pereent in each group diagnosed as hypertensive
70-89-----	0.3	0

Total-----	100.0	-----

¹ Data from a cooperative screening project at the District of Columbia General Hospital, Washington, D. C., results of which have not yet been published.

positive, but a great many cases would have been missed. Conversely, if the screening level is lowered in an attempt to pick up additional cases, smaller and smaller percentages of confirmations will be obtained, and the cost of finding these cases will involve the referral and examination of many persons representing false positive tests.

A second example, using blood sugar values, is shown in table 4, where a striking parallel to table 3 is seen. Again we find decreasing percentages of suspects if successively higher values are considered as screening levels. Accompanying these decreasing percentages, the proportions of confirmations of diabetes increase from 0 for persons screened at less than 70 mg., up to 100 percent at 200 mg. per 100 cc. and over. The same reciprocal relationship is evident here as was pointed out in the preceding example. Lowering the screening level makes it necessary to process larger and larger groups of suspects with a decreasing rate of confirmation.

"False-Positive" Results

In populations where the prevalence of a disease is low, furthermore, significant percentages of false positives must be expected in screening, even where measurements along a range of values, or gradient, may not be involved. Suppose, for example, that screening is being done for a disease actually present in

Table 4. Percentage distribution of blood sugar values on screening, and corresponding percentages of persons diagnosed as diabetic¹

Venous blood sugar value (mg. per 100 cc.)	Pereent of persons with indicated value at screening	Pereent in each group diagnosed as diabetic

Total-----	100.0	-----

¹ Data from a cooperative screening project at the District of Columbia General Hospital, Washington, D. C., results of which have not yet been published.

only about 2 percent of the screenees. In such a situation, let us assume a typical population of 1,000 persons, among whom 20 have the disease in question. Let us also assume a screening test which, applied to this group, will screen out 19 of the 20 diseased persons and only 19 others. Nineteen of these positives will then be verified by diagnosis and the other 19 will be diagnosed negative. Thus, 19 out of 38 screen positives are false, giving a "false-positive" rate of 50 percent. It would be a mistake, however, to condemn the screen test itself for this rate. Actually, a false-positive rate calculated in this manner is misleading, unless allowance is made for the fact that the rate depends on the prevalence of disease in the population screened. Nineteen of the twenty persons with the disease were properly classified by the test, and, therefore, sensitivity in this example is 19/20 or 95 percent. The specificity is 961/980, or 98 percent, since 961 of the 980 persons without the disease were correctly classified. Thus the screen test must be acknowledged to be highly efficient.

Planning the Project

The problems illustrated here lie at the root of much confusion regarding tests and standards, and have even cast doubt upon the feasibility of the screening approach in general. However, the same situation is faced in screen-

ing by any method that yields a wide range of values or deals with conditions of relatively low prevalence. It is more realistic and more productive—and in accord with medical traditions—to seek practical solutions to such problems, rather than to surrender for lack of perfect solutions.

Practical solutions must be sought in terms of the work involved in retesting and referral, the diagnostic workload that results from screening and retesting at any given level, and the resources required to meet the resulting diagnostic and care problems, as well as the costs incurred at each stage. The psychological effects upon the screenee cannot be overlooked. Particular care must be taken not to give him a false sense of confidence in the results of the screening test: He should be aware from the beginning that the screening is not a substitute for a complete health examination and that he is being tested for only certain specific conditions. Each local situation must be studied in the light of the possible effects of false positives and false negatives upon medical practice and on public reaction.

The local physicians and heads of clinics or hospitals, who will be expected to diagnose and treat the various conditions, should be included in the planning so that standards for screening, procedures and facilities for referral, diagnosis, treatment, rehabilitation, and education will be coordinated and have meaning for all concerned.

This cooperative planning should also deal with the problem of the person without frank disease who may have an abnormal condition in an early or incipient stage. Although frequently mentioned in the literature, such cases have not always been dealt with adequately in connection with screening programs. Decisions as to how this problem is to be handled have important implications for early case finding, for management of screenees and patients, and for the health education to be accomplished throughout the entire project. As indicated above, we can no longer think only in terms of the presence or absence of disease when dealing with deficiency and degenerative diseases. Many of the persons falling between the definitely normal and the definitely abnormal will not be regarded by their physicians as needing

medical supervision in the usual sense. The physician may, however, want to follow them because of the possibility of subsequent development of frank disease.

The objectives of a screening project should not only be discussed thoroughly and agreed upon definitely by those concerned, but should be expressed clearly in writing to avoid the possibility of later misunderstandings. Two major objectives—direct service to the public, and research—may be involved. If they are combined, each of these objectives will exert a limiting influence upon the other. Definite decisions as to the relative emphasis to be given to direct service and to research should be made in advance.

The kind of thorough planning indicated here for multiple screening and its ramifications will, of course, be familiar to those with experience in the public health field, since counterparts of the problems involved are found in the development of any public health program.

Evaluation of Multiple Screening

Although much progress has been made, multiple screening is still in an evolutionary stage. Screening and followup programs for syphilis and tuberculosis have been highly developed, but this is not true of screening for other diseases or for groups of diseases. Much remains to be learned through evaluation of multiple screening, in terms of accomplishments and costs of procedures to be followed at various stages from the original screening through the entire followup.

In the final analysis, of course, screening can be evaluated only by its results, such as reduced morbidity, disability, or mortality. Its ultimate value in the local community will be achieved as it becomes an integral part of a well-rounded chronic disease program, but on a limited scale multiple screening can serve to stimulate and guide the evolution of such a program.

A complete bibliography on multiple screening may be obtained upon request to the Publications Section, Division of Chronic Disease and Tuberculosis, Public Health Service, Washington 25, D. C.

Psychiatric Rehabilitation in the Hospital

By RICHARD H. WILLIAMS, Ph.D.

THE CONCEPT of rehabilitation is fairly clear-cut when one is dealing with amputees or with persons suffering from chronic neurological diseases. Everyone knows what is meant, and the results have been striking. But as the concept has become more generalized and is used to refer to still other diseases, including mental illnesses, it is not quite so clear.

Dr. Pearce Bailey has stated, "The current rehabilitation movement . . . is rooted in the concept that the mission of modern medicine must extend beyond definitive medical treatment to a program of dynamic therapeutics designed to bring the chronically ill patient to the highest functional level of physical, psychological, and socioeconomic adjustment compatible with his disability" (1). Such a program is limited only by maximal development of residual functions.

This statement is clear as to the objectives of rehabilitation. It is not, nor was it intended

to be, a definition because it does not delimit the process or operations involved. Furthermore, in a broad sense, all therapies have this same goal and may contribute to its realization. There has been considerable difficulty in demarcating a specific field of activities to be termed "rehabilitation," and there is some tendency to feel that rehabilitation is too loose a concept to warrant the development of a special program. On the other hand, there is a strong feeling that the goal of maximal development of residual functions requires a new orientation, the development of new techniques, and a new program if it is to be adequately attained.

The Rehabilitative Process

Several characteristics tend to distinguish the activities of people engaged in rehabilitation. A rehabilitation worker is often said to engage in adjunctive therapy as contrasted with specific medical therapy. Specific medical therapy is designed to cure, arrest, or mitigate a specific disease entity. Adjunctive therapy assumes an end product of specific therapy and is designed to restore or readjust the patient to the most adequate level of functioning of which he is capable, given this end product.

Dr. Howard A. Rusk's frequently used phrase "the third phase of medicine" also suggests a distinguishing characteristic of rehabilitation in terms of time. The rehabilitative process generally begins after diagnosis has been made and specific therapy used. It might be better to distinguish four phases of medical practice: prevention, diagnosis, specific treatment, and

Dr. Williams is social science research consultant in the professional services branch, National Institute of Mental Health, National Institutes of Health, Public Health Service. As a sociologist, Dr. Williams has served on the faculties and research staffs at Johns Hopkins and Wayne Universities. In Paris, he was professor at the Center of Sociological Studies and director of a Bureau of Industrial Psychology. In this paper, Dr. Williams deals with the same field as the forthcoming Public Health Monograph No. 17 in which Charlotte Green Schwartz reviews the literature on rehabilitation of mental hospital patients.

rehabilitation. To be sure, no very sharp lines can be drawn in terms of time. All phases may overlap in many cases. Yet these phases are distinguishable, with general, average differences in time as one of the variables.

Another distinguishing characteristic of the rehabilitation process is that, in addition to the various adjunctive therapies which will vary from case to case, a complete approach must be used. The patient must be understood as a whole person in relation to his family, community, and job possibilities. As Rusk has stated, "If a man has a hearing disability, has lost a leg, or has a cardiac condition, his disability affects all phases of his life. It has a bearing on his vocational opportunities, his family, his social life, his recreation, and his mental and emotional outlook. Individual disabilities cannot be treated in rehabilitation; the whole man must be treated" (2).

At a discernible point the patient begins to get an "outside" orientation, and to think of himself as an "ordinary social person" rather than as a "patient." There is a problem of the best time and means to get him to this point and to keep him oriented. Also, there is a problem of getting the patient "over the hump." In other words, there are critical points in the total treatment process which need special attention. A part of the hump which the patient must get over results from the gap which generally exists between hospitals and the community. There is a problem of how or in what ways this gap may be bridged.

In short, patients have many needs which have not been wholly met in the traditional therapies. There is a problem, then, of determining what services can meet these needs and the kinds of people with necessary training required to perform them. Among these needs the patient's occupational role and other aspects of his social role are particularly important.

We suggest that "therapy" and "treatment" may be used as generic terms, and that rehabilitation is a special form of therapy, albeit relatively nonspecific and holistic in its approach. Rehabilitation is that form of therapy which is primarily concerned with assisting the patient to achieve an optimal social role (in the family, in a job, in the community generally), within his capacities and potentialities. Psychiatric

rehabilitation is the application of rehabilitative therapy, thus defined, to mental and emotional disabilities. These disabilities may be primary or secondary. In its developmental research program, the National Institute of Mental Health began with the primary disorders—the psychoses.

Treatment a Continuum

Total treatment may be viewed as a continuum, with specific medical therapies defining one end of the scale and rehabilitative therapies defining the other. The specific medical therapies are primarily (but not exclusively) concerned with helping the patient to recover from his illness. The rehabilitative therapies are primarily concerned with helping the patient live with his illness or its residue and helping him develop substitute capabilities and new adjustments as needed. The nearer one is to the specific medical therapies on such a scale, the more one is concerned with operations within a distinctly medical and protective setting. The nearer one is to the other end of the scale, the more one is concerned with the patient's ultimate adjustment in nonmedical settings in the community. In the field of mental disorders, at one end of the scale (deep psychotherapy) one is concerned with remodeling the patient's basic character structure, whereas at the other end of the scale, the primary concern is getting the patient to function in the social process, with the character structure which he has.

These two orientations do and should shade into each other in the total process of treatment. There is no sharp division between them on a basis of time, as it may be highly advantageous to develop the rehabilitative aspects during an early stage of treatment. There is no 1 to 1 correlation between type of personnel and type of treatment on this continuum. Psychiatrists can, and should, concern themselves with the full range of treatment problems, including rehabilitation. By and large, personnel concerned primarily with rehabilitation do not have the required training to engage in specific medical therapies, although it is advantageous if they have some understanding of these therapies and can communicate easily with physicians. Some therapists, notably occupational therapists, occupy an intermediate

position: to facilitate the specific medical therapy, as prescribed by a physician, and to facilitate the rehabilitation process. Possibly the term "adjunctive" therapies will be gradually dropped, because it gives the impression of something added on, secondary and expendable. They might better be called rehabilitation services and considered as an integral part of total treatment.

The Importance of Research

Research in the field of psychiatric rehabilitation is in its infancy, but it has great potential importance for two basic reasons. In the first place, research is important operationally because it can lead to significant reductions in costs and wastage in the care of the mentally ill. As is well known, mental patients occupy more than one-half of our hospital beds, and the population in mental hospitals continues to increase—17 percent since 1939. There are a few private psychiatric hospitals, which provide good treatment and care, but they cannot possibly assume the whole burden of this large public health problem. State mental hospitals are generally overcrowded, and they are seriously understaffed.

There is considerable doubt as to the extent, if any, to which this increase is due to increases in the incidence of psychiatric disorders. Certainly, one of the major factors has been a series of changes in the organization and structure of the family, together with an increase in numbers of individuals who are detached and isolated from family groups. All of this has made it more difficult to tolerate and care for the mentally ill at home, individually and independently. Improved medical care has also reduced mortality rates in mental hospitals. Thus, the trend is toward higher admission rates and longer stay in the hospital, so that a large chronic population has developed.

It is not likely that a sufficient number of psychiatrists can be trained in the near future to meet the needs of the mentally ill for specific medical therapies. Given this situation, there is urgent need for research to determine the best ways to:

1. Prepare mental patients to live in less sheltered, less dependent, and less costly settings than the hospital.

2. Utilize all the hospital personnel, including psychiatric aides who have the most frequent contacts with patients, and utilize the entire hospital setting as a community to this purpose.

3. Mobilize existing resources in the community and create new, but less expensive, resources to maintain patients at an adequate level of functioning after they have left the hospital.

In the second place, research in psychiatric rehabilitation has a potentially significant contribution to make to basic scientific knowledge about mental disorders. Bailey (1) points out that the pathogenesis of neurological diseases is less well known than for other diseases. Hence there is more limited use of specific therapies and rehabilitation becomes all the more important. This statement applies equally well to mental illnesses. Furthermore, mental disorders, regardless of etiology, tend to involve disturbances in interpersonal relations and social adjustments in a direct way, more so than in most other illnesses. A significant proportion of mental disorders involve a failure of a person's system of behavior itself, rather than an inhibition of the system imposed by conditions stemming from the anatomical or biochemical systems of the organism—the "actor" is out of "whack," but the organism may be perfectly intact. Communication with others and emotional orientation to others are disturbed.

Rehabilitation of the mentally ill must thus be based primarily on an understanding of the emotional components of personality in the network of interpersonal relations, or, in other words, on the dynamics of social motivation. Research in psychiatric rehabilitation focused, as it must be, on ways in which patients may achieve an adequate social role and adequate functioning in the community, ways in which they may regain some interpersonal and social perspective, should contribute significantly to a basic understanding of this important component in mental disorders.

A Pilot Study

The National Institute of Mental Health is currently sponsoring a pilot study in rehabilitation at the Boston State Hospital under the

general guidance of the superintendent. A research psychiatrist is project director, and psychologists, sociologists, and social anthropologists are used on the research and advisory staffs of the project. It is now in its second year of operation. Operations were necessarily on a small scale during the first year, and it is expected to run at least 2 more years.

The study encompasses an experimental group and a control group, with 30 men and 30 women in each group, selected from the reception service wards, and experimental and control groups, with 40 men and 40 women in each group, selected from the chronic service wards.

Control patients receive whatever service the hospital is conventionally able to provide, which is minimal. For example, on the chronic service wards for men there are 2 social workers, 3 occupational therapists, and 1 recreational therapist to cover the needs of 700 or more patients.

The experimental groups receive additional rehabilitation services from personnel assigned directly to the pilot study and from regular hospital personnel. These services include recreational therapy, educational therapy and counseling, hospital industry counseling, the services of a full-time vocational rehabilitation counselor, occupational therapy and social service. Also, an explicit attempt is made to bring physicians, nurses, and ward care personnel into the rehabilitation team.

However, the project has been explicitly designed with a relatively small number of additional service personnel (there are only four full-time service personnel attached to the project). We are convinced that rehabilitation services do pay off and that it is not necessary to make large additions to service costs. When the project was expanded in scope for the second year, additional research personnel but not service personnel were provided. The addition of research personnel bears a relation to "capital gains" to be derived from a project of this sort, which is quite different from the situation created by the addition of service personnel. Costs of additional service personnel would continue indefinitely in duplicated projects, whereas other hospitals can use the knowledge gained without having research costs. The

latter is a primary objective of the project.

Definitive results are not yet available. Indeed, definitive results cannot be expected for at least 2 more years, because one of the criteria must necessarily be the extent to which patients can maintain themselves more independently over a period of time. Some experts consider 5 years to be a minimum period for making this judgment. The project has, however, learned much about methods of research in rehabilitation and about operational problems which are likely to be encountered. This is a type of knowledge which would be very useful to persons who might wish to introduce either research or service programs in other hospitals.

Considerations of Method

In a pilot research study, considerable time and effort must be spent to determine the methods of research which will be feasible within a given setting and which will most probably answer significant questions. In fact, one of the major purposes of a pilot study is to do just that and to pave the way for further and more detailed research. Six months were allowed for this purpose alone in the Boston State Hospital study before any of the action programs were initiated. As was expected, further experimentation with, and revision of, methods were necessary after the 6-month period.

Three major considerations of method, which would have to be faced in any study of a treatment program, have been explored:

1. Establishing experimental and control groups and the criteria for selection of patients in each.
2. Defining the variables to be measured or otherwise analyzed.
3. Selecting or developing tools for measurement or evaluation to obtain baseline data and later comparisons.

Selection of Groups

The establishment and composition of experimental and control groups on the reception service wards presented no serious difficulties, because existing administrative practices could be readily used for this purpose. This service has 6 similar wards in a 3-story building. The

2 wards, one for men and the other for women, on the third floor were arbitrarily chosen for the experimental patients, and the 2 wards on the second floor, for controls. Patients are assigned to these wards by rotation on admission, so that the composition of the group is determined by chance. Only committed and voluntary patients were chosen, patients for whom there is no arbitrary limit on hospital stay, thereby excluding certain other categories which are admitted for restricted periods of observation. However, if patients in these other categories were subsequently transferred to a committed or voluntary status they were involved in the study. The groups are thus composed of the first 30 patients on committed or voluntary status to be admitted to experimental or control wards, starting November 1, 1952, making a total of 120.

The establishment and composition of experimental and control groups from the very large chronic population presented numerous problems. Development of feasible and suitable means to solve these problems was a major accomplishment of the study during the first months. The final result has utilized five major steps:

1. An "eligible group," was designated according to the basic criteria of: (a) not under current treatment for physical illness; (b) under 60 years of age; (c) hospitalized for at least 1 year in the current illness. These criteria do not imply that excluded cases are incapable of profiting from rehabilitation services, but only that they involve different problems in rehabilitation, and we wished to focus the study more specifically.

2. "Prospects" were designated within the eligible group. Prospective patients for rehabilitation services were selected by the chief psychiatrist of the service on the basis of his personal knowledge of patients, a check on patients recommended as prospects by other service personnel, and a careful screening of all patients on ground parole. Severity of illness, potential responsiveness to treatment, and potential for achievement after discharge were all considered. It was specifically decided to include some of the more seriously ill patients, whose chances for being discharged within 1 year would be slight, because one of the aims

of the study is to determine what types of mental patients can best profit from rehabilitation services, and, consequently, the range of types should not be arbitrarily narrowed in advance.

3. A "drawing group" was obtained by cross-classification of all prospects by the three criteria mentioned above. Each patient was rated on a three-point scale for each criteria. Twenty-seven cells were thus formed, and a random selection of patients from each cell, in proportion to the numbers in each cell, was made to obtain a drawing group of 40.

4. The 40 members of the drawing group were matched with 40 members of the remaining prospects, according to 10 indexes.

5. Members of the 40 matched pairs were assigned to experimental and control groups by chance.

Analysis of the data after the selection was made indicates that "eligibles," "prospects," and study groups are very closely comparable in terms of level of hospital adjustment, so that we are most probably dealing with a broadly representative sample of chronic patients. About 80 percent of the prospects manifest an active paranoid or schizophrenic process. Also, it was possible to achieve very close matching between experimental and control groups. It was desired to develop methods of selection for the study which can be duplicated, which will not deviate markedly from hospital administrative practices, and which do not involve the use of complicated or expensive instruments (the validity of which has not been proved for rehabilitation, in any case). The method established came closest to satisfying all these considerations. Its feasibility, however, is dependent upon having a chief psychiatrist who has had sufficiently long contact with the patient group and who can be given the extra time necessary to make the selection of "prospects" from "eligibles."

Defining the Variables

Defining the variables to be studied also presents a crucial problem in any research program in rehabilitation. In a sense, our major variable is the introduction of a rehabilitation program in the experimental groups (and its

nonintroduction in the control groups), but it is apparent that this is a very complex variable indeed. Several rehabilitation techniques are being used. Also, and probably more important (for reasons to be indicated in another section), the study itself introduces new problems, new attitudes, and new interpersonal relations for all of the personnel. The problem of contamination of control groups is very real, especially in relation to the new attitudes which the study may generate. It would not be possible, short of an enormously complex and costly design, to isolate each aspect of the overall variable, a rehabilitation program, and study it separately under strictly experimental conditions. We do believe it is both feasible and potentially valuable to maintain the overall experimental design and then to develop accurate descriptions of the subvariables and intervening variables involved. For this reason primarily two full-time sociologists were added to the project staff. Undoubtedly, numerous subhypotheses will develop concerning the rehabilitation program which will lend themselves to scientific analysis now and possibly to experimental testing in subsequent studies.

Evaluation Tools

The selection or development of tools for measuring and evaluating the patients' status and movement is largely a problem of providing sufficient time and personnel to give a series of psychological tests and to use a number of rating devices. We are exploring a new field of developmental research, and we are not sure which psychological tests have adequate predictive value for rehabilitation potential. Several rating scales of hospital and post-hospital adjustment have been developed in quite recent years, but further exploration is necessary to determine their usefulness in a particular research setting. Thus, within reason, the more instruments used, the better. Some of them will turn out to have sufficient reliability and validity to be useful and others can be discarded later on.

A battery of 7 or 8 psychological tests and several rating scales, some of which can be used under careful supervision by personnel engaged in ward care, are currently being used. Con-

sultant psychologists and an additional full-time psychologist were added to the staff of the study to strengthen this aspect of data collection. In addition, detailed records are kept of the type and amount of the services given to experimental patients. It has been recognized from the first that a better in-hospital adjustment can be a legitimate goal in rehabilitation, and a legitimate criterion of success of the program, even though the patient may not be ready for discharge. Not only is the patient "better off" in terms of broadly accepted human values, but also he creates less demands on the hospital staff, thereby lowering the costs of his care. Consequently, periodic ratings are necessary, and it would be misleading to rely on discharge rates as the sole index or even to give them special weight.

Some Operational Problems

Numerous operational problems will be encountered whenever a new program is introduced into a large organization such as a State mental hospital. Both the formal administrative organization and the informal cultural atmosphere are likely to possess a certain rigidity and to be resistant to change. Two rather different attitudes may be taken toward such problems. On the one hand, they may be, and without great care are likely to be, regarded as "unenlightened" resistances to be overcome by all possible means. On the other hand, they may be regarded as representing very real forces in the social structure of the hospital, probably having important functional aspects, and, consequently, something to be understood, possibly modified, but not simply combated. The latter point of view has prevailed, wisely, we believe, in the Boston study.

Several of the operational problems encountered thus far revolve around the role of the ward physician. In the early stages of the study, it appeared that ward physicians were not making referrals for rehabilitation services (especially on the reception service wards) as frequently as would be expected or desired. Analysis showed that this was not due to blindly negative attitudes on the part of the physicians. They had suddenly been called upon to make a new type of referral and new

evaluations of patients for which they had not been prepared in their training, and no established routines existed. Also, examination of schedules revealed that the ward physicians did not have the necessary time to do the things they are supposed to do, according to general expectations. Furthermore, ward physicians are residents and are oriented toward their own training programs, which are heavily slanted in the direction of individual psychotherapy with patients (as a rule, with patients who are not on the same wards). The new rehabilitation program appeared as an additional hospital chore, taking valuable time away from training rather than adding to the value of the total training experience. The statement was made in a staff conference, for example, that if residents had a completely free choice they would not choose assignment to the experimental wards. Group conference techniques can, and have done, much to alter this pattern gradually, but it is deeply entrenched in the hospital culture and will have to be realistically faced in any rehabilitation program.

This example is but one of many of the general problems of facilitating communications and integrating a new program within the hospital. It has become a major goal of the pilot study to understand this problem as thoroughly as possible, rather than to treat it as a negative condition to be overcome, allowed for, or just tolerated. Such an orientation would certainly make it much easier to duplicate, in other hospitals, those phases of the action program which prove worthwhile.

Some Results From the Data

As indicated previously, definitive results in the sense of evaluating the rehabilitation program as such cannot be expected in the first years of a pilot study. However, such a study does produce other kinds of results in the form of new knowledge that is useful for a variety of purposes. Sometimes the facts may not be entirely new or unknown, but the research on a new problem lends new perspective to them, or gives them a greater emphasis than they had before. A few examples of areas of knowledge gained thus far in the Boston study are cited briefly to illustrate.

The hospital has been more accurately informed concerning what has actually been going on in terms of releases. It was necessary for the pilot study staff to make statistical analyses of releases during a sample year, giving numbers released, location within the hospital prior to release, length of hospitalization, age, sex, type of provision for care on release and returns to the hospital.

The reception service handles "new" admissions, but it does not follow that these patients have recent or acute cases. In fact, less than 50 percent of this group in the pilot study had come into the hospital for the first time. Some of them had as many as nine previous admissions to mental hospitals. It is a group representing a very wide range of problems in development and testing a rehabilitation program.

On the first trial run of selecting prospects among chronic patients from the eligible group, it was found that a surprisingly high proportion (roughly, 70 percent among the men) of the prospects had serious organic deficits along with their mental illness, including mental deficiency, alcoholism with organic residuals, and various pathologies of the central nervous system. On the other hand, they were people who caused little trouble in the hospital and who had made a reasonably good hospital adjustment as evidenced by ground parole and ability to perform some tasks in hospital industries. Further analysis raised serious doubts about their potential for adjustment outside of the hospital. Rehabilitation efforts in this direction might simply result in the transfer of a custodial problem from the hospital to some outside group. In any case, the group with serious deficits represents different and additional rehabilitation problems. Yet this is the group that hospital personnel tended to think of first as prospects for rehabilitation. These facts show that the selection of patients for intensive rehabilitation efforts is not a simple matter. In the Boston study there was need to broaden the base of selection so that an analysis could later be made of the most successful and the least successful types of cases.

It is known that the percentage of married patients in mental hospitals is low in comparison with the general population, but the extent of this difference is not often realized nor is its

importance sufficiently emphasized. About 70 percent of the male chronic prospects in the Boston study were "single." Thus, relations with a "family of procreation," that is, with a family in which one is a major responsible member (for example, husband and father), cannot be a part of the rehabilitation plan for many mental patients. The extent of the relation, and its potential usefulness, to a "family of orientation" (parents, siblings, or other relatives) is important to determine, as is the possibility of finding substitute groups for the family in many cases.

Interpersonal Relations and Attitudes

Charlotte Green Schwartz (3), in an analysis of the literature on the rehabilitation of mental hospital patients, draws an important distinction between rehabilitation programs which focus primarily on the interpersonal relations and attitudes which come into play and result from activities in the program, and programs which focus primarily on the nature of the activities themselves. The latter emphasis tends to give major attention to the individual patient and the particular activities (for example, occupational therapy and recreational programs) in which he has engaged, whereas the former tends to give major attention to the whole context of social participation in activities regardless of their specific nature. The evidence is not all collected concerning the relative values of these two approaches.

The definitions and general perspectives on psychiatric rehabilitation, suggested above, in which the dynamics of social motivation and social reactivation are crucial, would favor the hypothesis that interpersonal relations and attitudes are more important than the intrinsic nature of the activities themselves. Sociological research in other areas, such as industry or the armed services, give credence to this hypothesis (4, 5). If proved generally valid, it would have important implications for the development of training programs for rehabilitation personnel. Perhaps what is needed is a generic program which has major emphasis on social and psychological dynamics and provision for internships in which dynamic principles could be applied. In addition, there could

be some specialization within the generic program on activities such as crafts, manual arts, music, drama, vocational development, and adjustment.

The Mental Hospital as a Social System

There is growing awareness that the patterns of interpersonal relations and attitudes within an organization such as a hospital form a system, and that this system has profound effects upon all the participants. It controls and motivates their behavior to a very significant degree. Again, there is much sociological evidence concerning the nature and importance of this system in other fields, particularly industry and the armed services (4, 5). Schwartz (3) analyzes some of the quite recent studies of the social structure of the mental hospital, studies which are most challenging indeed. She also indicates, on the basis of evidence thus far, some of the characteristics of social structure which are presumed to be rehabilitative or vice versa, such as degree of democratization, effectiveness of channels of communication, and clarity of definition of functions.

One of the broadest visions of this range of factors and their potential therapeutic value has been developed by Dr. Maxwell Jones and his co-workers in England (6). They have also made one of the most explicit and thorough applications of these concepts in practice. A program for rehabilitation of the chronic unemployed with psychiatric difficulties has been established in the industrial neurosis unit at Belmont Hospital. So-called psychopaths and others with various disorders of character, usually termed "hopeless" cases, have been treated with better than expected success. This group is convinced that individual psychotherapy and hospitalization alone are not enough and that every aspect of the patient's life in the hospital community can and should be part of the total treatment program. Extensive use is made of conferences, discussion groups, psychodrama, and other forms of group participation. Explicit attention has been paid to the roles of physicians, nurses, and others on the staff and to the patterns of interpersonal relations and emotional dynamics which grow up around these roles. The constant aim is to integrate

these roles and to draw the patient into the total pattern, as a "therapeutic community," so that he can function more adequately in his social roles after discharge.

As this group clearly recognizes, every hospital has its social system, but much of it has been established on an intuitive or empirical basis, or has grown by the accretion of traditions. Efforts to direct the energies of the social system into therapeutic, including rehabilitative, channels should prove immensely fruitful. We are perhaps looking beyond the solid acquisitions of research, but we believe we are looking in a direction to which research already points the way.

Summary

Rehabilitation has been defined as that form of therapy which is primarily concerned with helping the patient to function optimally in society, within his capacities and potentialities. Research on psychiatric rehabilitation has high potential value, both in relation to programs of treatment and in relation to basic scientific knowledge about mental disorders.

In a pilot study of psychiatric rehabilitation in the hospital, much has been and is being learned concerning methods of research, operational problems encountered, and various facts about the population of a mental hospital.

The importance of interpersonal relations and attitudes and the value of mobilizing the forces in the social system within the hospital for therapeutic purposes have been emphasized.

We believe we are entering a period in which this type of knowledge will be increased, and operational procedures for its use will be thoroughly established. It should be a period in which significant gains are made in the treatment of the mentally ill and in an understanding of mental disorders.

Dr. Brownell Named Commissioner of Education

Dr. Samuel M. Brownell, 53, widely known educator, was named Commissioner of Education in the Department of Health, Education, and Welfare by President Eisenhower on October 14, 1953. He will succeed Dr. Lee M. Thurston, who died September 4, 1953, after having been in office for only 2 months.

The new chief of the Office of Education has been president of the New Haven State Teachers College in Connecticut since 1947 and professor of education administration at the Yale Graduate School since 1938. Dr. Brownell also has been a visiting lecturer in educa-

tion at the Universities of Cornell, Harvard, Michigan, Southern California, and Wisconsin. A native of Peru, Nebraska, he was a graduate of the University of Nebraska in 1921. He received his doctorate at Yale in 1926 and for 9 years was superintendent of schools at Grosse Point, Michigan.

Dr. Brownell is president of the division of higher education of the National Education Association and has been a frequent contributor of articles to professional journals.

Industrial Sickness Absenteeism

Rates for Specific Causes in 1952 for the year and last two quarters

Year 1952 Men and Women

The 1952 rate for sickness and nonindustrial injuries among men is approximately the same as for 1951—130.9 and 131.2 absences per 1,000 men, respectively. With only a few exceptions, the 1952 rates for specific causes and the corresponding 1951 rates do not differ greatly (table 1).

Among women, the 1952 overall rate of 344.9 is 9 percent above the 1951 rate of 315.1. The rate for the nonrespiratory-nondigestive disease group is 27 percent above the 1951 rate.

A comparison of the rates for men and women in the broad cause groups shows that rates for women in the respiratory and the nonrespiratory-nondigestive groups are approximately three times the corresponding rates for men. For nonindustrial injuries and the digestive group the rates for women are only about half again as large as the corresponding rates for men. On the other hand, the men employees had higher rates than women in 1952 for tuberculosis of the respiratory system; diseases of

the stomach except cancer; hernia; and diseases of the heart.

Years 1943-1952

An inspection of the previously published year-to-year rates for the 10 years, 1943-52, disclosed for both men and women an upward trend in the frequency of sickness and nonindustrial injuries that began in 1950 and continued through 1952. The upward trend among women was more pronounced than among men. Indeed, the 1952 rate for women (344.9) was the highest of the 10 annual rates, exceeding the 10-year average (262.2) by 32 percent.

Frequency by Duration

During 1952 approximately 7 of every 1,000 men and 8 of every 1,000 women experienced an illness that caused them to be away from work for more than half of the year (table 2). These absences were due primarily to nonrespiratory diseases. For both men and women only one-fifth of the respiratory absences lasted more than 1 month, whereas, more than one-half of the nonrespiratory absences lasted more than 1 month.

Days of Disability

The disability rate of 6.6 days per man in 1952 corresponds closely with the rate of 6.4 in 1951. Women averaged 13.2 days of disability in 1952 compared with 11.9 in 1951, approximately twice as many days of disability as the men. Among both the men and women, more than half of the lost time was due to nonrespiratory-nondigestive diseases (table 3).

Prepared by W. M. Gajafar, D.Sc., in charge of the statistical services of the Division of Occupational Health, Public Health Service, this report continues the series on industrial sickness absenteeism. Data are derived from periodic reports of industrial sick benefit organizations and are limited to sickness and nonindustrial injuries causing absence from work for more than 1 week. The report for 1951 and the first half of 1952 appeared in Public Health Reports, March 1953, pp. 353-357.

Men
Last Half
1952

During the last half of 1952 the sickness absenteeism rate among men employees for the third quarter was 103.8 per 1,000 men and for the fourth quarter, 123.1.

While the fourth quarter rates are generally higher than those for the third quarter, the rates for 1952, for either quarter, are remarkably similar to the corresponding rates for 1951 (table 4).

Table 2. Absences per 1,000 persons by duration—sickness and nonindustrial injuries disabling for 8 consecutive days or longer—year 1952

Duration of absence in calendar days	Sickness and non-industrial injuries ¹		Nonindustrial injuries		Respiratory diseases		Nonrespiratory diseases ²

Economic Benefits of Malaria Control In the Republic of Indonesia

By WARREN A. KETTERER, M.D., M.P.H.

PUBLIC HEALTH PROGRAMS beget long-range economic benefits which may appear obvious to public health workers but which are often overlooked in considerations of the economy of a nation. In the newly established Republic of Indonesia, such benefits, though difficult to determine precisely since sickness of all kinds is omnipresent and statistics are generally lacking, are becoming evident. The malaria control program, in operation by the Indonesian Ministry of Health with assistance from the Technical Cooperation Administration Mission (formerly the Economic Cooperation Administration Special Technical and Economic Mission) to Indonesia has provided data which are sufficiently reliable and significant to give some indication of its benefits to the economy of the country. These data, though as yet meager, also serve to emphasize the importance of public health endeavors in the underdeveloped countries of the world.

Indonesia, as well as having a high prevalence of tuberculosis, typhoid fever, yaws, leprosy, trachoma—in fact, most of the diseases known to man—is one of the world's most malarious areas. It has been estimated that malaria affects approximately 30 million of its 77 million people each year, causing more deaths than any

other disease and greatly limiting the productive capacity of the nation. The number of attacks of malaria infection each year undoubtedly outnumber the population. A spleen index of 80 percent has been found in many areas, and malaria epidemics have been known to kill one-fifth of the population of an area in a single year.

ECA assistance for the Indonesian Ministry of Health's malaria control program began in October 1950. By June 30, 1952, DDT-house-spraying operations had protected 999,000 persons in Java, Sumatra, Celebes, and Amboina from this disease. The malaria section of the Ministry directed \$400,000 in 1952 toward house-spraying activities and aimed at a population goal of nearly 2 million for the end of 1952. The World Health Organization has provided \$74,000 since 1950 for a malaria control demonstration area on the south coast of Java, and requested assistance from the United States foreign aid programs has totaled \$1,449,000, \$929,000 of this amount for DDT and the remainder for technical assistance, educational activities, and sprayers and other commodities needed for the program. The population goal of the spraying program for the end of 1953 is 5 million.

Benefits to Agriculture

A concept of the broad economic importance of the malaria control program in Indonesia can be obtained from the realization that the activities are carried out in areas which are predominantly agricultural. Thus, malaria

Dr. Ketterer has recently returned to the United States after a 2-year assignment as deputy chief of the public health division of the Technical Cooperation Administration Mission to Indonesia.

control contributes to the production of rice, which has been called the hinge of Indonesian economy, and of such products as rubber, copra, tobacco, tea, and palm oil, which are among the country's leading exports. With Indonesia importing 600,000 tons of rice yearly, an increase in rice production is perhaps of even greater economic importance in this country than it is in countries which export rice, since it should permit a reduction in expensive importation and in the use of foreign exchange.

DDT-spraying operations have made possible the reclaiming of idle rice fields in some areas and, together with improved agronomic practices, have led to an increase in yearly yield in others. Before World War II, rice fields frequently had to be drained and left to dry for several weeks to eradicate mosquito breeding and to reduce malaria. The DDT-spraying program makes this procedure unnecessary, permitting year-round cultivation.

Rice Production

Along the Bay of Banten in northwest Java, more than 10,000 acres of once highly productive rice land lay idle and deserted for several years after the Japanese occupation. The actions of the Japanese had destroyed the pre-war malaria control drainage system; and, as the drainage ditches silted up and salt water from the bay entered the rice fields, *Anopheles sundaicus* multiplied unchecked. The farmers remaining in the area, in their new concept of freedom, did not repair and maintain the permanent drainage system, but attempted to produce rice without regard for the threat of malaria. Malaria epidemics after 1944 affected more than 80 percent of the people, and the farmers were forced to abandon their land. The area soon reverted to tropical wilderness.

In September 1951, two DDT-house-spraying teams were sent into the area by the Indonesian Ministry of Health. As soon as the inhabitants nearby learned of the malaria control work, they began reclaiming the idle land. When the people came into the area, they found that malaria no longer decimated their population as it had done before the spraying.

By March 1952, 2,090 acres of this land were again under cultivation by old inhabitants, and 383 additional acres by new settlers (1). By

the fall of 1952, almost all of the area was under cultivation, and more farmers and their families were returning every day. When all 10,000 acres are again producing rice, it is expected that the yearly yield will be some 4,400 tons of husked rice to augment Indonesia's food supply. The total value of this rice should be approximately 8,380,000 rupiah (\$740,000); the total cost of the initial spraying operation was approximately 140,000 rupiah (\$12,000), less than 2 percent of the value of the yearly yield.

In addition to this program, the Ministry of Health plans to set up a yearly DDT barrier in this area between the coast and the inland. This should make possible the reclamation of another 18,000 acres of malaria-depopulated farmland because this DDT barrier will safeguard the inland area from mosquito-breeding places along the bay.

Export Products

A group of estates producing chiefly palm oil, but also other products, on the east coast of Sumatra were sprayed in 1950, protecting a population of 15,000. Evidence is available that malaria, which affected more than 80 percent of the population before the spraying activities, has been greatly reduced. Before spraying, examination of 402 babies revealed a parasite rate of 22 percent; the parasite rate in 298 infants born after the completion of spraying was 0 percent. The parasite rate in school children also declined, from 23 percent before spraying to 4 percent after.

Of great significance to the economy of the estates was the considerable decrease in admissions to the estate hospital after completion of the initial spraying. In the 11 months before spraying operations were begun, 2,363 patients were admitted, 700 of them with malaria. In the 11 months following spraying, 1,346 patients were admitted, 90 with malaria (1). The simultaneous decrease in illnesses aggravated by malaria, as reflected by the decrease in admissions excluding those for malaria, is characteristic. The decrease in hospital expenses alone was enough to finance the malaria control operations in this area. In addition, estate managers report a two-thirds decrease in absenteeism among the workers, resulting in an

increase in the number of working days and in production per man (1).

Transmigration Projects

Thirty years ago the Government of the Netherlands East Indies attempted a significant transmigration project in south Sumatra in an effort to relieve the population density in Java and to open new rice-producing areas. Malaria hindered the success of the project and curtailed the achievements planned for the area. Only with intensive use of expensive quinine could malaria mortality be maintained at a tolerable level. Late in 1951, DDT-spraying was commenced in the town of Metro, and by the end of 1952, 80,000 persons were protected from malaria. Continuation of the program will protect an additional 250,000 persons in this area (1). Already the transmigration area is becoming prosperous. Malaria rates are declining, additional land is being cleared, and new rice fields are opening up.

Another highly malarious transmigration area in North Celebes—around Dumoga—was sprayed in 1952. Before the war, transmigration attempts failed in six areas of Celebes because of malaria.

Other Benefits

Continued malaria control activities are also protecting the people in the major cities of Indonesia, among them Djakarta and Surabaya. In 1952, the hospitals of Djakarta reported a three-fifths reduction in admissions for malaria over the previous year.

In the coastal area around Djakarta, malaria control measures are benefiting the fishing industry. In the village of Marunda, 3 miles east of Tandjungpriok, *Plasmodium falciparum* infection has nearly disappeared. In 1949, the spleen index for children in this town was 91.5 percent and for adults 83.6 percent; malaria infection was totally absent in children born during the year after the spraying. In the village of Tjilintjing, 2 miles from Marunda, which was not sprayed, not only did the spleen index remain unchanged but a severe epidemic of malaria occurred (1).

On the prison island of Nusa Kambangan off

the south coast of Java, the habitations of its 9,680 persons were sprayed in mid-1952. Malaria was so serious on this island that the yearly cost of quinine for treatment was four times the cost of the malaria prevention operations.

In the area of Painan, Sumatra, which at one time had a spleen index of over 80 percent, 150,000 persons have been protected against malaria. Three months after spraying was begun in June 1952, the number of mosquitoes in the town itself had been so reduced that mosquito nets were no longer necessary.

In the fertile, but security-poor, area around Tjiandjur in central Java, the malaria control program has protected 190,000 persons. Ten months after spraying in an experimental area, the infant parasite rate was 0 percent; in a control (nonsprayed) area nearby, the rate was 18 percent (1). In their appeal for protection from malaria, local inhabitants guaranteed the safety of spraying crews in insecure areas.

Spraying of Tjilatjap, the only seaport on the south coast of Java, was begun in April 1952 and completed in June 1952, protecting 56,884 persons from malaria (1).

Summary

There is evidence that the malaria control program in Indonesia, which had protected nearly 1 million persons by the end of June 1952, is producing beneficial effects on several phases of the country's economy. Particularly important among these are the production of rice and such export products as rubber and palm oil, the establishment of transmigration projects, and the sea and inland fishing industry. In areas where DDT-house-spraying activities have been carried out, once-idle rice fields have been brought back under cultivation and new rice fields opened up; the number of hospital admissions for malaria, as well as the total number, have declined; and absenteeism among estate workers has decreased.

Glaucoma Case Finding in Philadelphia

By EMILY K. HANKLA

AT LEAST ONE-EIGHTH of the blindness in the United States is caused by glaucoma, according to some estimates (1), and with the aging of the population it is probable that this condition will increase in importance. Although there is general agreement among ophthalmologists that the most important factor in the management of chronic simple glaucoma is its early detection, only one mass case-finding campaign has been reported in detail, that of the Philadelphia Committee for the Prevention of Blindness.

From 1944 through 1950, the period covered by this report, a total of 10,000 persons was screened, the majority during the fiscal year 1950, when the Public Health Service supported the committee's work. Earlier papers by the executive director of the committee and by ophthalmologists who took part in the case-finding procedure have described the background, methods used, and results of the Philadelphia program (2, 3). This paper presents a detailed description of the population screened, the initial tonometer readings, and the case-finding yield at various tonometer readings above the screening level.

Screening and Retesting Examinations

The screening examination, which was performed by certified ophthalmologists, included

Miss Hankla is a statistician in the program analysis section, Division of Chronic Disease and Tuberculosis, Public Health Service. This case-finding program was conducted by the Philadelphia Committee for the Prevention of Blindness.

external examination for gross pathology, ophthalmoscopic examination of the fundus, visual acuity tests, and intraocular tension readings, using calibrated Schiøtz tonometers and a modification of the Schiøtz conversion chart (4). After these procedures ran smoothly, people were examined at the rate of 20 per hour. The screening tests were conducted in the plants where the screenees worked.

As has been found desirable in other mass case-finding programs, persons with positive screening results were retested before being referred to private physicians. Criteria for retesting were, in general, suspicious clinical findings or tonometer readings of 25 mm. Hg or more. The glaucoma screenee who returned for recheck might be classified as negative after a second or third tonometer reading; or before the examining physician decided upon a negative diagnosis or referral to a private physician, the screenee might have his fields of vision charted or a water provocative test or gonioscopic examination performed.

The retest clinic provided an additional service. Persons with borderline symptoms—persistent or intermittent tonometer readings of 28 to 30 mm. Hg and/or a rise of 6 to 8 mm. Hg on the Marx water-drinking test—were followed until a diagnosis of glaucoma could be established or ruled out. There were 71 such cases when they were classified in 1951 (3). In addition, there were 100 "observation" cases, persons with no indication of glaucoma except slightly to moderately elevated intraocular tension, a difference of 4 mm. or more in tension readings between eyes, or a family

increase in the number of working days and in production per man (1).

Transmigration Projects

Thirty years ago the Government of the Netherlands East Indies attempted a significant transmigration project in south Sumatra in an effort to relieve the population density in Java and to open new rice-producing areas. Malaria hindered the success of the project and curtailed the achievements planned for the area. Only with intensive use of expensive quinine could malaria mortality be maintained at a tolerable level. Late in 1951, DDT-spraying was commenced in the town of Metro, and by the end of 1952, 80,000 persons were protected from malaria. Continuation of the program will protect an additional 250,000 persons in this area (1). Already the transmigration area is becoming prosperous. Malaria rates are declining, additional land is being cleared, and new rice fields are opening up.

Another highly malarious transmigration area in North Celebes—around Dumoga—was sprayed in 1952. Before the war, transmigration attempts failed in six areas of Celebes because of malaria.

Other Benefits

Continued malaria control activities are also protecting the people in the major cities of Indonesia, among them Djakarta and Surabaya. In 1952, the hospitals of Djakarta reported a three-fifths reduction in admissions for malaria over the previous year.

In the coastal area around Djakarta, malaria control measures are benefiting the fishing industry. In the village of Marunda, 3 miles east of Tandjungpriok, *Plasmodium falciparum* infection has nearly disappeared. In 1949, the spleen index for children in this town was 91.5 percent and for adults 83.6 percent; malaria infection was totally absent in children born during the year after the spraying. In the village of Tjilintjing, 2 miles from Marunda, which was not sprayed, not only did the spleen index remain unchanged but a severe epidemic of malaria occurred (1).

On the prison island of Nusa Kambangan off

the south coast of Java, the habitations of its 9,680 persons were sprayed in mid-1952. Malaria was so serious on this island that the yearly cost of quinine for treatment was four times the cost of the malaria prevention operations.

In the area of Painan, Sumatra, which at one time had a spleen index of over 80 percent, 150,000 persons have been protected against malaria. Three months after spraying was begun in June 1952, the number of mosquitoes in the town itself had been so reduced that mosquito nets were no longer necessary.

In the fertile, but security-poor, area around Tjiandjur in central Java, the malaria control program has protected 190,000 persons. Ten months after spraying in an experimental area, the infant parasite rate was 0 percent; in a control (nonsprayed) area nearby, the rate was 18 percent (1). In their appeal for protection from malaria, local inhabitants guaranteed the safety of spraying crews in insecure areas.

Spraying of Tjilatjap, the only seaport on the south coast of Java, was begun in April 1952 and completed in June 1952, protecting 56,884 persons from malaria (1).

Summary

There is evidence that the malaria control program in Indonesia, which had protected nearly 1 million persons by the end of June 1952, is producing beneficial effects on several phases of the country's economy. Particularly important among these are the production of rice and such export products as rubber and palm oil, the establishment of transmigration projects, and the sea and inland fishing industry. In areas where DDT-house-spraying activities have been carried out, once-idle rice fields have been brought back under cultivation and new rice fields opened up; the number of hospital admissions for malaria, as well as the total number, have declined; and absenteeism among estate workers has decreased.

Glaucoma Case Finding in Philadelphia

By EMILY K. HANKLA

AT LEAST ONE-EIGHTH of the blindness in the United States is caused by glaucoma, according to some estimates (1), and with the aging of the population it is probable that this condition will increase in importance. Although there is general agreement among ophthalmologists that the most important factor in the management of chronic simple glaucoma is its early detection, only one mass case-finding campaign has been reported in detail, that of the Philadelphia Committee for the Prevention of Blindness.

From 1944 through 1950, the period covered by this report, a total of 10,000 persons was screened, the majority during the fiscal year 1950, when the Public Health Service supported the committee's work. Earlier papers by the executive director of the committee and by ophthalmologists who took part in the case-finding procedure have described the background, methods used, and results of the Philadelphia program (2, 3). This paper presents a detailed description of the population screened, the initial tonometer readings, and the case-finding yield at various tonometer readings above the screening level.

Screening and Retesting Examinations

The screening examination, which was performed by certified ophthalmologists, included

Miss Hankla is a statistician in the program analysis section, Division of Chronic Disease and Tuberculosis, Public Health Service. This case-finding program was conducted by the Philadelphia Committee for the Prevention of Blindness.

external examination for gross pathology, ophthalmoscopic examination of the fundus, visual acuity tests, and intraocular tension readings, using calibrated Schiøtz tonometers and a modification of the Schiøtz conversion chart (4). After these procedures ran smoothly, people were examined at the rate of 20 per hour. The screening tests were conducted in the plants where the screenees worked.

As has been found desirable in other mass case-finding programs, persons with positive screening results were retested before being referred to private physicians. Criteria for retesting were, in general, suspicious clinical findings or tonometer readings of 25 mm. Hg or more. The glaucoma screenee who returned for recheck might be classified as negative after a second or third tonometer reading; or before the examining physician decided upon a negative diagnosis or referral to a private physician, the screenee might have his fields of vision charted or a water provocative test or gonioscopic examination performed.

The retest clinic provided an additional service. Persons with borderline symptoms—persistent or intermittent tonometer readings of 28 to 30 mm. Hg and/or a rise of 6 to 8 mm. Hg on the Marx water-drinking test—were followed until a diagnosis of glaucoma could be established or ruled out. There were 71 such cases when they were classified in 1951 (3). In addition, there were 100 "observation" cases, persons with no indication of glaucoma except slightly to moderately elevated intraocular tension, a difference of 4 mm. or more in tension readings between eyes, or a family

increase in the number of working days and in production per man (1).

Transmigration Projects

Thirty years ago the Government of the Netherlands East Indies attempted a significant transmigration project in south Sumatra in an effort to relieve the population density in Java and to open new rice-producing areas. Malaria hindered the success of the project and curtailed the achievements planned for the area. Only with intensive use of expensive quinine could malaria mortality be maintained at a tolerable level. Late in 1951, DDT-spraying was commenced in the town of Metro, and by the end of 1952, 80,000 persons were protected from malaria. Continuation of the program will protect an additional 250,000 persons in this area (1). Already the transmigration area is becoming prosperous. Malaria rates are declining, additional land is being cleared, and new rice fields are opening up.

Another highly malarious transmigration area in North Celebes—around Dumoga—was sprayed in 1952. Before the war, transmigration attempts failed in six areas of Celebes because of malaria.

Other Benefits

Continued malaria control activities are also protecting the people in the major cities of Indonesia, among them Djakarta and Surabaya. In 1952, the hospitals of Djakarta reported a three-fifths reduction in admissions for malaria over the previous year.

In the coastal area around Djakarta, malaria control measures are benefiting the fishing industry. In the village of Marunda, 3 miles east of Tandjungpriok, *Plasmodium falciparum* infection has nearly disappeared. In 1949, the spleen index for children in this town was 91.5 percent and for adults 83.6 percent; malaria infection was totally absent in children born during the year after the spraying. In the village of Tjilintjing, 2 miles from Marunda, which was not sprayed, not only did the spleen index remain unchanged but a severe epidemic of malaria occurred (1).

On the prison island of Nusa Kambangan off

the south coast of Java, the habitations of its 9,680 persons were sprayed in mid-1952. Malaria was so serious on this island that the yearly cost of quinine for treatment was four times the cost of the malaria prevention operations.

In the area of Painan, Sumatra, which at one time had a spleen index of over 80 percent, 150,000 persons have been protected against malaria. Three months after spraying was begun in June 1952, the number of mosquitoes in the town itself had been so reduced that mosquito nets were no longer necessary.

In the fertile, but security-poor, area around Tjiandjur in central Java, the malaria control program has protected 190,000 persons. Ten months after spraying in an experimental area, the infant parasite rate was 0 percent; in a control (nonsprayed) area nearby, the rate was 18 percent (1). In their appeal for protection from malaria, local inhabitants guaranteed the safety of spraying crews in insecure areas.

Spraying of Tjilatjap, the only seaport on the south coast of Java, was begun in April 1952 and completed in June 1952, protecting 56,884 persons from malaria (1).

Summary

There is evidence that the malaria control program in Indonesia, which had protected nearly 1 million persons by the end of June 1952, is producing beneficial effects on several phases of the country's economy. Particularly important among these are the production of rice and such export products as rubber and palm oil, the establishment of transmigration projects, and the sea and inland fishing industry. In areas where DDT-house-spraying activities have been carried out, once-idle rice fields have been brought back under cultivation and new rice fields opened up; the number of hospital admissions for malaria, as well as the total number, have declined; and absenteeism among estate workers has decreased.

according to a calibration chart, the positions of a wavering pointer on a small scale.

To illustrate, more than one-fifth (22 percent) of the group tested had initial tensions of 22 mm. Hg, the modal, median, and mean reading for the eye with the highest tension. On both sides of this peak, there were fewer readings than would be expected in a normal distribution. For only 322 persons was the initial high tension given as 21 mm. Hg. On the right-hand side of the mode, the slope is more regular but there are only 3 millimeters between the modal value and 25 mm. Hg, which was adopted as the screening level. The wide and one-sided range at the base, from 11 to 65 mm. Hg, with a few high values representing the more abnormal or unusual occurrences, is also characteristic of measurements of blood pressure, blood sugar, or hemoglobin.

Of the 9,645 persons with tonometer readings for both eyes, 1,056 (11 percent) had intraocular tensions in one or both eyes equivalent to 25 mm. Hg or more, the screening level which had been adopted. Of these, 815 were called back for reexamination or put under medical care. Glaucoma or "borderline" intraocular tension was diagnosed in 21.2 percent of the 1,056 suspects with initial tensions of 25 mm. Hg or more, or 2.2 percent of the total number screened. Virtually none of the glaucoma patients had any previous knowledge of their disease.

In figure 2, tension readings above the screening level of 25 mm. Hg have been grouped in 3 mm. intervals. Even in the first interval, among those with initial readings of 25 through 27 who were retested, 10 percent (32 cases) were classified as having glaucoma or "borderline" tensions. With higher initial readings, the percentage of positive classifications increased. Original tonometer readings of 40 mm. Hg Schiøtz or higher were followed in all instances by diagnoses of glaucoma.

It should be noted, though, that the cases picked up at the 40 mm. Hg Schiøtz screening level numbered only 20, compared with 32 instances of glaucoma or "borderline" intraocular tension with initial readings of 25 to 27 mm. Hg and 90 at the 28 to 30 mm. Hg level. Moreover, all but one case with initial tensions of 40 mm. Hg or more were later classified as advanced

Figure 1. Number of persons tested, by initial tonometer reading (in mm. Hg Schiøtz).

glaucoma, while 95 cases (78 percent) with original tensions of 25 to 30 mm. Hg were either early glaucoma or "borderline" intraocular tension. (See figure 3.)

Age and Intraocular Tension

With age there is an increase in the percentage diagnosed as having glaucoma or "borderline" intraocular tension, as may readily be seen in table 2.

If all cases are grouped together, and distributed by their age, their ratio to the total num-

Figure 2. Percentage of persons with confirmed glaucoma or "borderline" intraocular tension who had initial tonometer readings (in mm. Hg (Schiøtz) of 25 or more.

examination, and diagnosis. For those with "borderline" tonometer readings and negative diagnoses, the tests should be repeated at intervals. Investigation is needed before we can estimate how elevated tension must be to be regarded as dangerous. Such a study would furnish a basis for estimating the number of those who might be inaccurately classified as negative in a mass screening survey. These data would enable us to compare "borderline" screening levels for sensitivity as well as specificity.

Further investigation of screening methods is fundamental to a public health approach to this problem. Although without some count of the "false negatives," we cannot accurately estimate the size and cost of the problem of undiscovered glaucoma, we know that it is large and expensive. The cost of services to the blind paid from taxes or privately donated funds has been estimated to be in excess of \$125,000,000 per year (1, 9). This sum does not include expenditures by relatives or by blind persons themselves. Nor does it include the costs of unemployment caused by blindness or any of the economic costs of partial vision.

Summary

Among 10,000 working people screened for chronic simple glaucoma by the Philadelphia Committee for the Prevention of Blindness, no differences in frequency were found by race and sex, within age groups. More cases of chronic simple glaucoma are found in the older age

groups; these cases are likely to be advanced.

The higher the intraocular tension, as indicated by a Schiøtz tonometer reading, the more specific is the indication of glaucoma, especially of advanced glaucoma. On the other hand, the "borderline" tension levels are most productive of "borderline" cases.

The need for more study, with emphasis on long-term followup of "borderline" cases, is evident from the data.

Departmental Council Formed To Aid Secretary

To achieve maximum coordination in the administration of the Department of Health, Education, and Welfare, the Secretary has created a Departmental Council composed of top officials and heads of constituent units of the Department. Henry G. Haskell, Jr., of Wilmington, Del., has been named as secretary of the Council.

Disinfecting Garbage in Truck Bodies

By Direct Steam Injection

By HERBERT A. BEVIS, B.C.E., M.S.E., FRANK TETZLAFF, C.E., M.C.E.,
and FLOYD B. TAYLOR, B.S.S.E., M.P.H.

FEEDING of raw garbage has been shown to be the primary mode of transmission of trichinosis in swine (1) and thus is indirectly the source of human infection. It is felt that this practice contributes greatly toward the dissemination and perpetuation of other swine diseases.

The escape of vesicular exanthema, a highly contagious swine disease, from its two-decade isolation in the swine herds of California and its subsequent wildfire spread through the herds of the Nation have further motivated a critical review of the practice of feeding garbage to swine. The exact path the disease followed from the time it escaped from California until it was detected among swine at a hog cholera serum plant in Nebraska was investigated by the United States Department of Agriculture and various State agencies concerned. Indications were that garbage containing infected pork scraps had been fed raw to swine at a farm in Wyoming and that infected animals had been shipped to other areas of the country be-

fore the disease was recognized. As of May 1953, 468 of 493 herds in which the disease had appeared had been fed raw garbage, and outbreaks had occurred in 41 States (2).

The work of Wright and Bozicevich (3) showed that the worm *Trichinella spiralis*, the infectious agent in trichinosis, could be destroyed or made nonviable by subjecting pork scraps containing the organism to adequate heat. The degree of heat that constitutes adequate treatment will depend upon the thickness of the pork scraps and the duration of heat. Experiments have shown that the actual temperature required throughout the mass to destroy *Trichinella spiralis* is 131° F. (4) and a temperature of 145° F. maintained for 30 minutes is thought to render the virus of vesicular exanthema nonviable (5). However, the work of Wright and Bozicevich (3) led to the conclusion that for practical purposes disinfection of the garbage by boiling for 30 minutes was desirable and that this degree of heat treatment is sufficient to "effect the destruction of trichina larvae in pieces of pork up to 3 inches in thickness and probably in pieces of pork of greater thickness provided the garbage is allowed to cook gradually." This statement is the basis for general recommendation that all garbage be boiled for at least 30 minutes prior to feeding to swine unless some other manner of disinfection is approved by health or agricultural authorities concerned as being equally effective.

Mr. Bevis is sanitary engineering consultant to the National Park Service for Public Health Service, Region III; Mr. Tetzlaff is regional engineer in the Region II office; and Mr. Taylor, a sanitary engineer formerly with Region II, is now assigned to the Clinical Center, National Institutes of Health.

The application of this heat treatment principle on a nationwide basis in England and Canada tends to substantiate the experimental work. In these two countries, where garbage is cooked prior to swine feeding, most swine diseases have practically disappeared and the incidence of trichinosis in humans is estimated to be only about 1 case in 75 persons (6). In the United States, where raw garbage is used as swine feed, the incidence of trichinosis in humans is estimated to be 1 case in 6 persons (7). More accurate figures on the prevalence of this disease are not available due to its many manifestations and the absence of a specific diagnostic confirmation other than recovery of the organism by biopsy.

If garbage, a valuable waste product of the American home, is to continue to be reclaimed in the form of pork, some economical method of disinfecting it must be found.

At the present time the general feeling among the swine farmers of the country is that an installation which could provide the necessary heat treatment of garbage in the truck in which it was collected would be most practical. This procedure would eliminate the necessity of re-handling the waste and would thus be a saving in time and labor. In order to ascertain if such treatment in truck bodies could produce satisfactory temperatures, the Region II office of the Public Health Service conducted an experiment at the North Bergen Stock Farm, North Bergen, N. J., during February, March, and April 1953 on the heat treatment of garbage in truck bodies, using direct steam injection as the source of heat and agitation.

Equipment

The truck used in this experiment was equipped with a rectangular metal tank body 15 feet long, 8 feet wide, and 34 inches deep. The tank was covered with semicylindrical sliding doors and had two arched wheel wells over the rear wheels of the truck.

A 2-inch steam supply line entered the tank high on the left side of the front, ran across to the middle of the front, and down to the bottom, where it was connected to a 1½-inch header. From the header, 1-inch laterals, numbering from four to seven during the course of

the experiment, were run the length of the tank to distribute the heat. One-eighth inch holes were drilled on a horizontal plane through both walls of each lateral, on 12-inch centers in the forward half of the tank and on 6-inch centers in the rear half. Where necessary, the laterals were curved over the two arched wheel wells and welded in place.

A 2-inch flexible rubber hose fastened to a universal coupling by a heavy-duty hose connection was used to connect the steam manifold system in the truck to a 150-hp, oil-fired, horizontal boiler. This boiler was capable of providing steam at a pressure of 125 psi, but in this series of tests the automatic control was set to maintain a pressure between 45 and 55 psi. As these tests were being run the boiler was concurrently providing heat for the animal barns.

A specially designed, portable, three-pen recording thermometer was used to record temperatures at various points in the garbage mass during each cooking cycle. This instrument had a class IV thermal system (liquid expansion), 0°–300° F. temperature range, a mechanically driven clock on a 24-hour cycle, and three 14-foot acid-resistant leads (10 feet flexible and 4 feet rigid stainless steel).

A wooden beam was used to support the thermometer leads in the garbage mass during each test, with the thermometer bulb located at the end of each lead. The locations of the leads were varied during the tests, as shown in the table.

Procedure

Prior to each test in this experiment, the garbage, which had been collected from the hotels and restaurants of New York City during the preceding night, was leveled in the tank with a garden rake. Often this garbage was of such a solid nature that a man experienced no difficulty in walking on top of it as it was prepared for treatment. Three to six inches of clearance was normally allowed between the surface of the waste and the rim of the tank to accommodate the accumulation of steam condensate. Under these conditions the tank held about 300 cubic feet (2,244 gal.) of waste, which weighed from 8 to 10 tons.

After the garbage had been leveled, the ther-

(A) Interior of truck, showing seven distribution laterals. (B) Ground key blowoff valves for laterals, located under rear of truck. (C) Portable recording thermometer with 3 bulbs and 3 indicating pens. (D) Thermometer bulbs placed in garbage and held secure by wooden support.

monometer support was placed across the tank above the section of the truck body to be investigated during the test. The three thermometer bulbs were inserted into the garbage through holes in the timber to the desired depth and were locked in place with set screws. By varying the location of the thermometer bulbs longitudinally, laterally, and vertically, temperatures in all sections of the tank were investigated during the course of the experiment.

The steam was turned on after the initial temperature of the garbage mass had been determined. Erratic heat distribution in the first tests quickly established the need for a means of eliminating condensate and garbage liquor, which tended to clog the lines, and blowoff valves were installed. During the tests made after the valves were installed, the laterals were drained as soon as pressure was applied to the system, and any condensate or garbage liquor in the lines was removed. This draining opera-

tion was repeated several times during each test.

When the desired temperature had been reached and maintained for the required length of time the steam was turned off and the garbage was allowed to cool. The thermometer bulbs remained in the mass during the first part of this cooling period in order to ascertain the cooling characteristics of each section of the tank. The center portions of the garbage cooled very slowly and it was normally the following day before it was unloaded and fed to swine.

Since the tests were conducted out of doors the atmospheric temperature was noted during each run.

Results

In the first series of tests in this experiment a steam distribution system was used. The system contained 4 laterals connected to the main

header across the front of the tank, and spaced on 30-inch centers. The 2 outside laterals were elbowed and extended about 3 feet across the rear of the tank. When steam was introduced into the garbage mass through this system, a liquid channel soon formed directly above each lateral and most of the steam took this path of least resistance to escape. This flow of steam caused a mound of waste to be thrown up between the laterals which heat did not penetrate. Upon one occasion, after 4 hours of heating, including 3 hours of boiling in the watery channels, a temperature of 98° F. was found in 1 of these mounds.

In an effort to overcome this channeling tendency, 2 additional laterals were added, making a total of 6 laterals on 16-inch centers.

The elbowed extensions of the two outside laterals across the rear of the tank had been found to be ineffective, and were omitted. This new design reduced the channeling tendency, but a critical condition was located directly behind the wheel wells on each side of the tank. Either condensate or garbage liquor appeared to be filling the pipe lines at a point immediately after they curved over the wheel wells, and very little steam reached the garbage in these two areas. The design did produce acceptable results on occasions but generally the results were erratic and uncertain.

To eliminate channeling completely, the number of laterals was increased to 7, on 14-inch centers, and to remove condensate and garbage liquor from the lines, each lateral was

elbowed down through the rear of the tank bottom and terminated with a 1-inch ground key blow-off valve. A watertight, bolted, and removable tail gate necessitated placing the valves under the tank rather than on the rear wall. This improved design gave a uniform distribution of steam and normally produced acceptable heat treatment. A tabulation of the results of eight runs using this improved design is given in the table.

Several times during the course of the experiment "dead spots" were located in the garbage mass which heat did not penetrate. These spots were usually in a tightly packed wad of material held together by napkins or papers.

After a uniform distribution of steam was obtained, heat was found to rise to the surface of the mass in a distinct horizontal blanket except around the perimeter of the tank, where steam followed the metal sides to the surface very quickly.

Conclusions and Comments

1. Garbage can be disinfected in a metal tank truck body using steam injected directly into the mass through laterals placed on 14-inch centers and terminated with blowoff valves. (There were seven laterals in the truck body used in the experiment.) Due to the many possible sources of error in this type of system, however, steam injection in truck bodies is not the ultimate solution to the problem, either from the viewpoint of the operator or of the regulatory agency, and this system of treating garbage with heat should be used only as an interim measure until a properly designed built-in-place installation is available.

As a result of an analysis of general steampipe layout design procedures, made after completion of the heat treatment experiment, the following theoretical conclusions seemed indicated:

(a) The cross-sectional areas of the header pipe should be approximately equal to or slightly larger than the cross-sectional area of the supply line.

(b) The total cross-sectional area of the laterals should be approximately equal to the cross-sectional area of the header pipe.

(c) The aggregate area of the drilled holes should be approximately one-half that of the steam supply line. In general, the smaller the aggregate area of the holes, the more uniform the steam flow will be out of each hole, and smaller holes will allow the use of a greater number of holes, thus insuring more even heat distribution through the garbage.

These theoretical conclusions may be checked in future experiments.

2. Separation of edible and nonedible waste material is very desirable. However, if any glass bottles should accidentally be included in the garbage they will not be broken by this type of heat treatment.

3. Breaking up any semisolid masses of material as the garbage is placed in the tank will help reduce the possibility of "dead spots" and inadequate heat penetration.

4. Manual agitation of the garbage with a wooden paddle will help insure proper distribution of heat.

5. Three to six inches should be allowed between the surface of the garbage and the top of the tank to prevent spillage when steam condensate accumulates.

6. The surface of the garbage should be covered to conserve heat and prevent spattering. If possible, the treatment should be provided in an insulated building, especially during the winter.

7. Laterals should be blown off as soon as steam pressure is applied and at half-hour intervals thereafter.

8. The equipment should be cleaned after each use. Special care should be given to the interior of steam lines and orifices because cooked garbage is sucked into the lines by the vacuum formed when the steam pressure is turned off. This cooked garbage will solidify as it cools and may block the line.

9. Uniform spacing of orifices on 6-inch centers over the entire length of the laterals would probably produce results as good as, if not better than, the results obtained with this equipment.

10. When the cooked garbage is allowed to cool in the tank it usually requires up to 24 hours for it to cool sufficiently to be fed to swine. This means the truck in which garbage is treated would be out of service every other

such categorization of health activities has some utility in relation to research, dissemination of knowledge concerning particular health hazards and the methods for dealing with them, and the securing of support for public action.

Official health agencies, however, are seldom organized solely along special purpose lines. Executive, supportive, and even substantive program services which contribute to the execution of a particular health program are often provided by organizational units not a part of the specific program staff. Furthermore, local health services are usually carried out by a general staff which has responsibility for conducting a public health operation encompassing all categories of programs.

Accounting in this situation would be greatly simplified under either 1 of 2 conditions: the financing of all programs from one fund, or the administration of each program by a single organizational unit supported from one fund. Neither solution is entirely practicable. Legislative program authorization by major purpose and implementing appropriations usually make financing from one fund impossible. The excessive costs of duplicating specialized personnel (by discipline or by process) make separate administration of each program impractical.

The State health department accountant is therefore faced with a task of setting up an accounting system which produces expenditure data by funds (purpose), responsible organization, activity, and object. To do this requires a great number of detailed accounts. The number of original entry accounts for a typical program is illustrated in the chart by the number of lines leading to the symbols at the bottom representing the various funds. The increase in object accounts, because of the addition of one more fund, or organization, or activity is obvious.

Proper accounting for funds spent on a public health program becomes more difficult when costs of program coordination, administrative staff services, or special professional services must be identified. What the accountant needs is a device which may be adjusted to the necessities of program administration. Fund accounting is too inflexible and cumbersome in complex program situations to justify the

bookkeeping cost involved. Under the fund accounting procedures which were first used in many States it was not unusual to find a local health officer or public health nurse receiving 4 or 5 separate salary checks each pay period. Their services contributed to many programs, and from each they received separate recompense. This situation was improved somewhat by a more judicious budgetary allocation of funds. But there is an accounting concept that can be used to further simplify the handling of special purpose funds in administrative situations in which both general and special purpose activities are involved. This is the concept of the revolving fund.

Application of revolving fund techniques to accounting for special purpose health grants depends upon the ability of the grantee to make disbursements for salaries, supplies, contractual services, rentals, equipment, and other items, from a single account. Federal requirements which originally prevented any application of revolving fund techniques to grant fund accounting have been eliminated through a series of amendments to the grant-in-aid regulations. First, a requirement that State accounting and disbursing officials maintain separate and distinct fund accounts was amended in 1943 to permit State treasurers to consolidate grant funds with other moneys in accounting for the custody of cash received by the States. Then, in 1949 the commingling of grant funds to the extent of consolidating all health grants in one account on the books of the principal State accounting officer was permitted. At the discretion of the State, the State health executive may now be the only State official responsible for keeping a separate account for the receipt and disbursement of each health grant.

With Federal requirements no longer a barrier to the use of simpler fund accounting techniques, in 1951 the grant operations branch of the Division of State Grants of the Public Health Service approached a few fiscal officers of State health departments to discover if they found the idea of a single grant operating account feasible and worth special study. Individual fiscal officers and members of the Subcommittee on Fiscal Affairs of the Federal Relations Committee of the Conference of State and Territorial Health Officers ap-

Nature and Purpose of Local Health Unit Record and Report Systems

Largely by means of excerpts, the author of the concurrently issued Public Health Monograph presents here the main points of her thesis that records and reports are basic elements in any health department operation, that they require the thoughtful consideration and imaginative evaluation not only of those who maintain them but also of those who create and utilize them. On page 1081 the content of the monograph is outlined.

Records and reports represent an important aspect of public health administration. A more active exchange of experience and observations by means of technical papers and critical evaluations would tend to improve and strengthen current practice. The editors of Public Health Reports are prepared to facilitate such an exchange and will welcome receipt of appropriate manuscripts.

• • •

Records aid in promoting continuity of service and provide source material for periodic and special analytical reports. Thus, records and statistical reports may be looked upon as distinct entities: Records are written statements noting facts and events pertaining to an individual or establishment. Reports are accounts, statistical summaries, or statements of relationships of pertinent material obtained from records.

Medical and nursing records in local health departments contain entries of the findings, observations, services given, and recommendations regarding individuals and members of their families; sanitation records contain entries of the findings, recommendations, and action of the health department regarding premises and establishments. These records are used by:

Medical staff to refer to the past history of the individual, to provide a source of data for special epidemiological and other research

studies, and to furnish materials for resident training and staff education.

Nursing staff to provide a tool for adequate nursing service to the individual and his family and for correlation of nursing services with the services given by other members of the health department staff, to furnish a means of integrating health department services with those of other agencies in the community, and to provide material which will aid in the inservice training and supervision of the staff.

Sanitation staff to provide source material for analyzing program operations, special problems, and personnel activities, and to furnish data for staff education.

Administrative staff to provide a source of information that is necessary for administrative coordination and control of each program, for evaluation of services furnished, for evidence in legal action, and for information to be used in answering authorized requests from other agencies.

Reports measure the services given by the local health department. They are needed to evaluate the general and specific programs of each division of the department in relation to the needs of the community, to determine the problems arising in each program, to direct the programs toward future needs, to analyze services in relation to administrative procedures and costs, to evaluate the achievements of department personnel and the efficiency of each division, to compare activities of the department with the work of similar agencies, and to provide material for public information and health education. Individual and family records form the basis for reports.

Basic Problems

Self-appraisal of record and report systems in local health departments has revealed that existing records and reports frequently are not meeting the health department needs. Staff members are becoming increasingly aware that records and reports serve their purpose only when they meet the specific needs of the administrative, medical, nursing, and sanitation staffs.

The objectives of the organization determine the content and function of records and re-

ports. Content and function, in turn, determine the source of material, the method of recording, the data to be recorded, the number of personnel to be employed, and the systems, methods, and procedures to be developed. To adopt a form or a procedure without considering the preliminary steps breeds confusion and waste. It is just as inconsistent to continue the same procedures year after year without reviewing the objectives.

However, many local health departments have maintained the record and report procedures started many years ago to assist in serving and appraising the programs then in existence. Since communicable disease was the focus of attention, service was directed to the case. Each case was considered an entity, and for some individuals several records were on file. This type of record system is a handicap to the health workers of today because current programs are directing attention to the individual and his family. A longer time period is involved; socioeconomic factors must be considered. The value of a continuous record of services given to each individual is recognized. Reference to these records reveals information on the individual's health history, social and economic problems, previous illnesses, results of diagnostic tests and therapy, and staff recommendations. When the records are not combined, it is difficult for the attending physician and nurse to refer to all records of an individual. There is frequently no way of knowing that the person has been seen or is at present being seen by another staff member. Duplications of service and of diagnostic tests may result; contrary recommendations may be made.

Similarly, the statistical reports that are prepared in many health departments were created and have been developed primarily to obtain a count of services given. The type of report which results does not present the data that are essential today. There is a continuing need to study the objectives of each program to determine the data necessary for evaluating service given and determining service and personnel required.

No health department can satisfactorily adopt the record and report forms or systems of another health organization without analysis of the suitability or usefulness of the data re-

Outline of Content of Public Health Monograph No. 15

Many local health departments have recently studied their record and report systems and have found it necessary and desirable to develop simpler, more effective, and more adaptable procedures. Findings and recommendations presented in Public Health Monograph No. 15, "Records and Reports of Local Health Departments—Criteria and Methods for Organization, Maintenance, and Use," are based on surveys of systems used in 25 local health departments in 8 States and an demonstration projects in a city and a city-county health organization, which were conducted at the request of the State and local health departments concerned. The studies and demonstrations were sponsored by the Division of Public Health Methods and the Division of State Grants of the Public Health Service.

The monograph illustrates a method in which the staff of various divisions of a health department, working in collaboration, critically examine each record and report maintained by the department. This self-appraisal is considered as an essential step in improving the usefulness of each record and in developing a system of records and reports that will meet the needs of all units of the health department. Principles of organization and detailed explanations of the mechanics of recordkeeping are given. The principles and methods described are not dependent on the size of organizations involved; they are applicable equally to small and large health departments.

Application of principles as carried out in a demonstration project—a city health department serving a population of over 500,000—is described

in some detail, beginning with the initiation of the project. Considerations involved in installing the record and report systems are reviewed, with discussion of problems associated with selecting and tabulating minimum data and with establishing an office of records and reports. The record and report procedures followed by each person concerned are outlined.

Supplementing this demonstration area material are six "case studies" illustrative of the greater accessibility, uniformity, and usefulness of local health department records which can be achieved through reorganization. Diagrammatic representations of the systems support the examples, which are:

Case I. Medical and nursing records in a health center in a city-county health department.

Case II. Medical and nursing records in a three-county unit health department.

Case III. Medical and nursing records in a health center in a city-county health department.

Case IV. Sanitation records in a city-county health department.

Case V. Establishing a central index in a city-county health department.

Case VI. Facilitating interchange of information among a health organization's units.

Included in the appendix to the monograph is a statement of basic principles governing service statistics in public health, as prepared by a working group of the Public Health Conference on Records and Statistics in 1951.

training clerical personnel. Central control of clerical services should facilitate the installation of standard procedures and aid in the elimination of duplication. It should also permit greater utilization of clerks by making possible the transfer of employees from one office to another, for example, during the time of the day when there is a peak load in one office and a slack period in another or when an employee is absent from duty.

Meeting Community Needs Economically

Recognition of the adequacy or inadequacy of existing systems is an essential step in determining the need for records and reports. This often leads to clarification of problems existing in the administration of health services and frequently results in coordination, increased efficiency, and economy of services.

Health department services—and, reflecting

these services, their record and report systems—vary with community population and habits, climate and topography, natural resources, and the available personnel, facilities, and functions of other health agencies in the community. The variance among programs in scope and development emphasizes the value of analyzing activities and achievements against

the background of community requirements. Analytical reports, in addition, can serve as tools for the evaluation of performance of staff members, can aid in the study of administrative procedures, and can furnish data essential for informing the community of its resources for health service and unmet needs.

The Growth of Local Health Units in Florida

By WILSON T. SOWDER, M.D., M.P.H.

TO A CONSIDERABLE DEGREE, any separation of local health services from services provided by other government echelons is artificial and somewhat illusory. Perhaps some persons interested in the subject would define local health services as those that are completely financed and administered by local governments. If such a definition is accepted and interpreted strictly, Florida would have few local health services to report. In fact, there are few public health services in the State which are not supported to some extent, directly or indirectly, by State or Federal funds and which are free entirely from some legal control, under State or Federal laws. In this paper, therefore, will be described the development of those public health services which are financed and administered, in whole or in part, by local governmental agencies; and it will be left to the reader to accept or reject this definition.

Facts about local health services during the several centuries of the Spanish regime and during the brief British occupation are fragmentary or lacking. However, in 1821, Gen-

eral Andrew Jackson, in his capacity as Governor of the Territory, issued a proclamation setting up a board of health in Pensacola and appointing a health officer.

The present State constitution, which was adopted in 1885, not only provides for a State board of health, to have supervision over all public health matters in the State, but also provides that county boards of health "may be established." The State board of health was established by legislative action in 1889, after a severe yellow fever epidemic, and county boards of health were provided for by statute and appointed within the next several years.

However, even before the turn of the century, the State health officer had recommended the abolition of the county boards of health and the legislature had complied. This course was taken because each county board of health had not only adopted its own regulations for the control of communicable diseases, especially yellow fever, but these regulations were enforced with varying degrees of zeal, usually too much. Most funds and energy were spent on quarantine procedures, with special emphasis on the exclusion of travelers and goods from areas suspected of infection, and written permission was necessary from each county involved before travel could be undertaken. Such actions resulted in "Iron Curtains" between the counties of the State, since communicable diseases were frequently present and oftener rumored. The abolition of county boards of health was therefore probably quite justified and necessary in order to end this state of chaos, and to bring about uniformity in

Dr. Sowder has been State health officer of Florida since 1945. Previously, he served in various national and regional venereal disease control posts, and in State and local health department assignments, including that of health officer of Hillsborough County, Fla., in 1941-42. He was commissioned in the Public Health Service in 1934 and is on leave to serve in his present post.

health laws, regulations, and practices throughout Florida. Following this action, for the next 30 years and more, except in the larger cities and towns, public health services were provided by persons employed directly by the State board of health.

County Health Departments

The present era of local health administration began in 1930 with the passage of a State law authorizing joint financing between counties and administration of county health units by boards of county commissioners and the State board of health, and cooperation with

cities. Funds were to be deposited in the State treasury to the credit of the county involved. Minimum personnel required included a physician, a public health nurse, a sanitary officer, and a clerk, who were required to devote their entire time to public health work. Personnel were to be appointed by boards of county commissioners with the approval of the State health officer and their salaries were to be fixed by the State health officer with the approval of the board of county commissioners. Multicounty units were authorized with common budgets and personnel.

This excellent law has been so entirely satisfactory that no attempt has ever been made to

Table 2. Total and per capita expenditures of Florida county health units, by source of funds, at 5-year intervals, 1930-53

change it. Soon after its passage the first health unit was established in Taylor County, a small rural county in west Florida. Although this unit was discontinued after a short existence, it was soon reinstated and there has been a steady growth of the county health unit system since the passage of the county health unit enabling act. Table 1 shows concisely the increase in the number of organized counties among Florida's 67 counties, the population and percentage of population served, the increase in funds available, and the number of personnel employed. Table 2 shows expenditures and per capita expenditures by source, for each of the 5-year periods since 1930. Figure 1 shows graphically the expenditures for county health units for the period and the source of funds, Federal, State and local. Figure 2 shows the per capita expenditures by county health units and the sources, Federal, State and local. In interpreting these charts it should be kept in mind that Florida's population has increased rapidly. According to the Federal census, in 1930, the increase was 1,468,211; in 1940, 1,897,414; and in 1950, 2,771,305.

It should not be assumed that per capita expenditures are uniform among the counties of the State. On the contrary, there is a wide variation. Local appropriations vary from a minimum of 34 cents per capita to a maximum of \$1.89 per capita; and the total of Federal and State funds allocated to local health departments varies from a minimum of 23 cents per capita to a maximum of \$1.78 per capita. State and Federal funds are distributed among the counties on a formula basis, according to the population of the county, the per capita amount decreasing with increase in population. In order to encourage local appropriations, the formula includes a matching factor so that larger per capita local appropriations are matched by somewhat more State and Federal funds. The smallest grant of State and Federal funds (1953-54) is \$3,915 and the largest, \$114,466.

Additional funds not shown in the tables and charts are also allocated on a project basis to 12 of the larger counties for special programs which are conducted on a regional basis. These programs include cancer, heart disease control, and mental health, and the total funds so allocated during the present fiscal year (1953-54) amount to \$99,900.

Direct aid to local health departments in

Figure 2. Per capita expenditures and source of funds of Florida county health units.

the school health program was brought about with the cooperation and agreement of all concerned. A law was passed which applied to Dade County only and which effectively removed any legal barriers to the consolidation. The law also set up an advisory board which functions as a local board of health except that it has no administrative functions or authority to promulgate regulations.

Under this plan the county undertook the entire responsibility for financing the operations of the health department, except for available Federal and State funds. This arrangement has worked out so satisfactorily that it has been used as an example of the benefit of consolidating the city and county governments entirely, and this development failed by a narrow margin in a recent election.

A similar development started somewhat earlier in Hillsborough County, whose chief city is Tampa. In spite of some opposition at first from rural areas and from one small town, the consolidation was promoted by the parent-teacher association because of a desire to have better school health services. Past efforts to carry on a separate school health program had not been satisfactory, and school officials were loathe to provide for an expensive school health program which would overlap the activities of the city and county health departments.

A few years later, and without much public fanfare, city and county officials in Pinellas County (St. Petersburg-Clearwater) agreed upon a consolidation, and effected it by legislative action. In this case, a local board of health was provided, the only one in the State.

Even before these consolidations took place, most of the smaller cities and towns in the State had effected similar arrangements by negotiation and agreement, and without special laws. In Pensacola and Escambia County, for example, a city-county health department was operated for years under a single health officer, with each agency paying its own employees. In recent years city, county, and State appropriations have been put into a common fund. While the trend in recent years has been for the counties to assume the entire local financial burden, in 1953, 27 municipalities contributed a total of \$65,890 to county health department budgets.

Consolidation has not meant that the cities of Florida lack health departments. Acting under specific agreements, and under the general policy of the State board of health, each county health department serves as the municipal health department for each municipality within the county, unless the municipality has a health department of its own. The county health departments are obligated to enforce municipal health ordinances, and in fact the county health departments would be greatly handicapped in their work but for the existence of such ordinances. This is particularly true in the field of milk and food sanitation where there is some dispersion of responsibility among State agencies.

At the present time only the city of Jacksonville has a complete and fairly adequately financed city health department. It has a budget of about \$500,000 to serve a population of more than 200,000 people. The cities of West Palm Beach, Orlando, and Lakeland have city health departments, but these furnish only limited public health services, and their combined budget for this purpose is estimated at less than \$100,000. Public health services in these cities are supplemented by the county health departments. It can be seen, therefore, that of a total of about \$4,339,320 spent by local health agencies in Florida only about \$665,000 is appropriated by municipalities, and most of this is spent by the city of Jacksonville.

School Health Services

Sentiment in Florida has always been against the development of separate school health services financed and administered by education agencies. In the past, many local school boards provided for school health services, particularly public health nursing services. There has been a continuous trend in recent years to discontinue this activity, or to merge such efforts with the county health departments. In many counties, the board of county commissioners bears the entire local cost of public health services, including school health services, but at present in 39 counties the local school boards make a contribution to the common fund of the health department. The total amount so contributed in the 1952-53

budgets was \$142,602. This assistance is especially important since it is contributed primarily in the smaller rural counties.

It is especially interesting that the Florida laws governing the expenditures of school funds provide that these can only be spent for local services where the county health department is unable to provide needed services. At the present time, in only 7 counties are public health personnel employed by school boards other than through county health departments. This personnel consists of 19 public health nurses and 1 health educator. In 1 of these counties, although 4 public health nurses are paid directly by the local school board they work under the supervision of the county health

officer. In the other counties, they work in close cooperation with the personnel of the county health departments, and the outlook for a complete merger of efforts in the future is very bright.

Summary

During the past 23 years steady progress has been made toward statewide coverage by county health departments, and only one county, with a population of 27,200, is now unorganized. Similar progress has been made in the coordination and unification of local health services provided by counties, municipalities, local school boards, and the Florida State Board of Health.

Birth and Early Days of Florida's First County Health Unit

By W. H. Y. SMITH, M.D., C.P.H.

WHEN THE Taylor County Health Unit was established in Florida during August 1930, it arrived, with the help of the Public Health Service, on a scene which was not only beginning to feel the full impact of a depression but which was already burdened by an abundance of malaria and hookworm disease.

From this county's swamp swarmed the *Anopheles quadrimaculatus* mosquitoes, and in its sandy soil thrived the hookworm larvae. It was a county rich in its land from the trees, yet poor in its soil that was cultivated. From its great sawmills and lumber towns came the money and from the country came the poor.

The health unit consisted of a motley group of "foreigners." To this unsuspecting community came a nurse from Tennessee, a sanitation officer from Massachusetts, the health officer from Canada, and a secretary who was the only native-born denizen.

In the beginning, the three moving pieces of personnel—the nurse, the sanitation officer, and the health officer—studied their maps and planned their strategy. Then they moved out

Florida's experience in developing local health services is reviewed by Dr. Sowder in the preceding paper. He speaks of 1930 legislation and establishment that year in Taylor County of the State's first local unit.

This informal account of the creation and early days of the Taylor County Unit is taken from remarks at the 1952 meeting of the Florida Public Health Association by the unit's first-health officer, Dr. W. H. Y. Smith, now director of the bureau of preventable diseases in the State Health Department of Alabama.

To pioneers and veterans of the local—and particularly of the rural—health movement, this vignette may evoke a degree of nostalgia. To some who have not had the privilege of working the back roads in some variety of shoe-leather epidemiology, nursing, or sanitation, it may even have an odd and distant tone. But to those who today are dealing, face-to-face, with problems of local health service, many elements and incidents in this flashback to two decades ago will seem remarkably current.

in their separate ways for personal appearances and good will tours in the county and were greeted quite often with blank stares and a thinly veiled hostility. Yet, there was always the one or the two, uninformed and hookwormy or malarial as he or they might be, who accepted the "pearls of wisdom" that were being dispensed and nodded vigorously and who, almost at once, became an ally and supporter. And with these allies and supporters the beginning was made in the communities.

Sanitation in the towns was relatively good and screening reasonably well done because the lumber industries through past years had learned or had been shown the worthwhileness of such things, and, too, most townspeople were used to such conveniences. But from the edge of one town to the edge of the next industrialized town and through those towns without industries there was a lack of these antihookworm and antimalarial facilities. And most of the people were ignorant in the ways of preventive medicine and health and were resistant to any and all innovations. "What was good enough for pappy is good enough for me" was their determined song. And the string trio of health workers were just as determined to play a new tune. But the tune was a simple melody. Funds were lacking for a great crescendo of music with brass and winds and piano for a mass attack of drainage ditch and privy building. Yet slowly but surely the nurse found her way into homes and the sanitation officer's spot map began to show evidence of privy building.

Then arose a new kind of resistance. The beautiful screened doors were kicked out because mamma couldn't get the door opened fast enough to throw out the dirty dish water or because the screens kept out the fresh air. And the privies went unused. Perhaps, the classic example of the latter was the family of eight who were filled to overflowing with hookworms. They lived deep in the country and were all potbellied and pasty faced. They were too sick for the usual remedy of carbon tetrachloride and so the new drug hexylresorcinol was used. During the several stages of treatment a new and shiny privy was built by the sanitation officer and his helpers, who explained the facts of privy life to the family. They

would nod their heads and smile in simple agreement, but the privy remained unused. One day, the old man explained why. They were so grateful for the return of their health that they couldn't possibly use the beautiful new house that the health unit had built for them for that desecrating purpose.

As a help in getting across the story of health, moving pictures were used. The traveling members of the unit would visit each home and invite everyone to the free pictures. In one home the nurse encountered stonewall resistance when the mother of a brood of hookwormy children said there was no such thing as hookworms, and if there was a moving picture of them it was made up because you couldn't take a picture of something that wasn't.

Interlaced with the educational programs and privy building were the hookworm treatment clinics. Through the schools, class by class, and in the homes, specimen tins were given out and carbon tetrachloride was given to the positives. The list was always long and at times, in some schools, there were no negatives. It was thought that repeated treatments might slow down the infestations even though the privy building program hadn't reached or wasn't yet accepted in the areas. Future survey proved this point.

The antimalaria program moved forward slowly. To accelerate it, quinine clinics were held throughout the county one summer. Once a week the people were met and given quinine capsules and instructed how to take them prophylactically. Neighbor told neighbor and the numbers at the clinic increased week by week. It appeared for a time that this type of clinic was being highly successful because of the crowds. But there was a flaw. Although they were only given enough quinine sulfate for the family for one week of prophylaxis, they didn't use it that way. This was discovered when one man at a clinic refused quinine, saying that he had enough now to last him for years. Apparently they didn't take the medicine as directed but put it on the shelf awaiting the time they would have chills and fever.

Inroads, of course, were made in the other communicable diseases but nothing was done about venereal diseases. Those were the days of men's doctors, secretiveness, and disgrace.

By the end of the first year, the unit was fairly firmly established with many people. But with the county commissioners it was different because the unit was dealing with new officials, not the ones who established it. There were two for, two against, and one on the fence. It was the one on the fence that had to be convinced. So at budget time the commissioner's room was filled with health unit supporters. The country people came on foot and in wagons, and the ones from industry and the clubs came in automobiles. And industry didn't send little wheels, they sent big ones. They all crowded into the little room—well-dressed men and women against a background of faded and patched overalls and shirts and snuff and chewing tobacco. It was hot and stuffy, and the unwashed bodies perspired freely with the washed ones until the commissioners were convinced.

Then the second year rolled around and

there was a repeat performance of the previous year. But industry didn't send such big wheels because it felt the health unit was old enough to stand on its own feet. It should have been, but the grapevine said the commissioners again were divided. But again the pressure was strong enough to continue the work for another year.

When the third year ended, it was decided to turn off the pressure. Either the past performance of health was apparent or it wasn't. To the people it was but not to the commissioners. They threw out the health unit, lock, stock, and barrel and replaced it with a nurse.

It is hard to express the feelings of a group of pioneers in health who tried to do a good job and succeeded only in being considered expendable and unnecessary. But bitterness and resentment were replaced as the feeling of success slowly seeped in again . . . for Taylor County remained without a health unit for just 1 year.

Public Health Service Staff Announcements

Dr. Lloyd D. Felton, an outstanding authority in bacteriology and immunology and a commissioned officer of the Public Health Service, died September 11, 1953. He devoted his entire career to laboratory research and medical teaching—at Johns Hopkins Medical School, Rockefeller Institute for Medical Research, and Harvard University's Medical School and School of Public Health. Dr. Felton's extensive studies of the virulence of bacteria led to the discovery of the Felton serum used in the treatment of pneumonia. Also, Dr. Felton discovered an antigen for immunization against pneumonia and introduced methods of standardization which enable physicians to determine the proper dosages of antibodies for the treatment of the disease. He contributed much toward the development of the sulfa drugs and during World War I made intensive studies of meningitis for the Army Medical Corps. He had been ill of a heart disease for more than 2 years. Before his illness, he was chief of the pneumonia unit in the Division of Infectious Diseases at the National Institutes of Health from 1938 to 1949. Dr. Felton's home was at 125 E. Thornapple St., Chevy Chase, Md. Burial was in Arlington Cemetery.

Dr. Albert M. Kessel, head of the pathological technology section of the laboratory of pathology, National Cancer Institute, Public Health Service, was killed in the crash of a Belgian airliner near Frankfurt, Germany, October 14. His wife and daughter were also killed in the crash. Dr. Kessel, with the National Cancer Institute since 1940, was on a vacation trip to Germany, where he was born in 1909. At the Institute, Dr. Kessel did research work in micro-anatomic fixation techniques and microscope slide staining methods. He was curator and assistant instructor in neuro-anatomy at the Mt. Sinai Hospital in New York City from 1929 to 1936.

Dr. Byron C. Brunstetter, secretary of the hematology and pathology study sections, Division of Research Grants, National Institutes of Health, was killed in a plane crash near Albany, N. Y., on September 16, while on an official trip, reviewing the projects of NIH grantees. Dr. Brunstetter had been with the Division of Research Grants staff since 1948, first as chief of the research fellowships branch. Since 1951 he had also served as chairman of the board of civil service examiners at the National Institutes of Health.

Public Health Aspects of Civil Defense

By DALE C. CAMERON, M.D., M.P.H.

MAJOR attacks upon the United States by an enemy possessing weapons of modern warfare could produce millions of casualties, making necessary the provision of both medical care and public health services on a scale unprecedented in the history of the world. Already much planning and preparation have gone into the organization of civil defense health services, but much more has yet to be done.

The primary considerations in this paper are the problems involved in providing public health services. Space does not permit a detailed analysis of the many problems involved in providing emergency medical care, but these problems are inexorably intertwined with the public health problems, as will be evident from the discussion. Basic to an understanding of the health aspects of civil defense is a knowledge of the nature of the threat and the requisites for an adequate defense.

Nature of Threat

The effectiveness and limitations of weapons which may be used and the targets susceptible

of destruction by these weapons are outlined below, and some comments are made on enemy capabilities and objectives.

Nature of Weapons

The weapons which must be taken into account in preparing for enemy health services include biological, chemical, radiological, and atomic warfare agents. Since the threat from atomic weapons has been discussed extensively elsewhere (1, 2), this discussion will be limited to other unconventional weapons.

Biological warfare agents include living organisms, toxins, biological products, and chemical plant growth regulators, which may be used to produce deaths or casualties in man, animals, or plants. The possible use of such agents as an instrument of warfare has intrigued the imagination of war planners for centuries. Although disease and epidemics among men have materially affected the course of many wars, recorded instances of deliberate attempts to affect the enemy are few. They provide no objective data on the use and effectiveness of biological agents in actual modern warfare.

Estimates of potential performance of biological agents must rest largely on extrapolation from preventive and treatment experimental data, epidemiology of accidental laboratory infections, hypotheses, and an extensive knowledge of man's ceaseless struggle against human, animal, and crop diseases during the ages. Since most of the problems of waging biological warfare are technical, it must be

Dr. Cameron is medical consultant in the Office of Health Emergency Planning, Office of the Surgeon General, Public Health Service. He participated in the preparation of the Project East River Report on Civil Defense for the Department of Defense, the Federal Civil Defense Administration, and the former National Security Resources Board, from November 1951 to June 1952.

assumed that they either have been solved or that satisfactory solutions are possible. Civil defense today must therefore take into account the possible use of biological agents.

Chemical warfare agents include toxic chemicals, incendiaries, and smokes, which may be used to produce deaths or casualties in man, to destroy material, or to provide screening operations against enemy weapons or intelligence. Modern chemistry has added materially to the ways in which the ancient and potent weapon of fire can be used. World War I demonstrated conclusively that toxic chemicals also can be used effectively against man and animals. These facts plus the recent development of nerve gas make it imperative that civil defense preparations include provisions for possible attack with chemical agents.

Radiological warfare agents include radioactive materials, other than atomic bombs. These may be used to impair or kill man, animals, or plants, or to deny or impede access to contaminated objects or areas through threat of casualties. If these agents are used against this country, it would probably be primarily to deny or impede access to contaminated areas and to create confusion rather than to produce physical casualties. Radiological warfare is not viewed as nearly as serious a threat as biological, chemical or atomic warfare at the present time.

Viewed as antipersonnel weapons, biological and chemical agents could rival atomic bombs in destructiveness. From the public health point of view, the problems presented by the possible use of biological and chemical agents of warfare are at least as serious as those involved in possible radiological or atomic attack.

Nature of Target

The targets of these weapons are man, animals, crops, and physical things. Only atomic bombs, high explosives, fire, and certain chemical agents are particularly useful against both living and inanimate targets, but biological and other chemical agents could be used effectively against man, animals, and crops without destroying other things.

Considering man as a target, enormous num-

bers of casualties could result from overt attack with biological or chemical warfare agents, as well as with atomic bombs. Correct use of biological agents by saboteurs could cause large numbers of primary casualties and disruption among selected local population groups, but the secondary spread of disease among men after either covert or overt attack probably would not be especially great, particularly if appropriate public health measures are in effect. The covert use of chemical warfare agents presents more technical difficulties than such use of biological warfare agents.

Animals and fowls are seriously vulnerable to attack with biological agents, and the secondary spread of disease would probably be extensive and fairly rapid. The use of biological warfare agents against crops and forests also appears to present a serious threat if these agents are introduced at the proper time and place by either overt or covert means. The secondary spread of disease among crops and forests is also likely to be extensive, but the buildup would be slower than that among animals.

Enemy Capabilities and Objectives

The use of these special weapons against us depends not only on the vulnerability of targets but on the enemy's capabilities of production and delivery and upon his objectives and intent. Little can be said about enemy capabilities, but scientific knowledge concerning biological, chemical, and atomic warfare is not restricted to the free nations. Public statements have been made by Government officials to the effect that a potential adversary probably has the ability to deliver whatever weapons he has available (3, 4). Thus it is important not to underestimate enemy capabilities.

An enemy's objectives and intent, together with enemy capabilities and target vulnerability, play a vital role in our defense efforts. People will prepare to defend themselves against a particular threat only if they perceive it as real and relatively imminent. Perhaps some of our delay in the development of an effective biological and chemical warfare defense is predicated on a general belief that an enemy would not wish to use such agents on our vul-

nerable targets even if he had the weapons and means of delivery. Consideration of an enemy's objectives and intent is in the realm of pure speculation, but two points deserve mention.

One of these is the possibility of a future world war being based on a different concept from those of the past. The past two wars were waged primarily against things. An effort was made to destroy the productive capacity of nations, a concept brought sharply into focus by strategic bombing to destroy vital links in the production machine. True, men who were in the way were killed or injured, but the primary target, generally, was the industrial productive capacity. The result has been that many countries, victorious and vanquished alike, have required outside aid during the post-war period in providing food and clothing for their people and in rehabilitating their industries. Many of these postwar sequelae could be avoided by waging a war primarily against man, with the result that the survivors would be fewer in number and would probably have ample physical resources for their sustenance.

It may be argued that our enemies would not attempt to assist this country as we have tried to assist war-torn countries in the past, and this is probably true as far as humanitarian motives are concerned. But consider why potential foes would want to conquer this Nation. It seems reasonable to assume that their purpose would be to control our productivity in order that they might exploit our economy for their benefit. If this be true, then it also seems reasonable to assume that potential enemies might be interested in preserving, insofar as possible, our industrial capacity, and that, therefore, a future war might be against man rather than against things. Chemical and biological agents would become particularly attractive weapons in such a war.

A second point to be considered in speculating on enemy objectives is the fact that biological and chemical agents, particularly the former, lend themselves admirably to covert attack. The possibilities of weapons particularly useful as covert agents surely would not go unrecognized by an enemy who has a penchant for doing everything possible within his means, short of all-out war, to achieve his ends.

Requisites for Civil Defense

Both military measures and civil measures are necessary for the provision of an adequate defense against enemy attack with modern warfare weapons.

Military Measures

Dr. Lloyd V. Berkner in an address at the Minnesota World Affairs Center, University of Minnesota, on September 29, 1952, pointed out that the single most important military factor in our present foreign policy is the development of a strategic striking force (5). He noted further, however, that regardless of the merits of this concept, there comes a time when this approach is not enough. When an enemy has built up a sufficiently large striking force of his own to deliver a "knockout blow," the threat of retaliation loses much of its meaning. Thus, not only must this country develop a strong right arm, but it must also have an effective shield so that it may survive to use the strong right arm.

Such a shield is essential not only from the foreign policy point of view but also from the civil defense standpoint. Only with such a shield can the civil defense problem be made manageable. This country does not have unlimited personnel and physical resources to expend on civil defense efforts. If civil defense is to be successful, the magnitude of the task must be manageable. Any leak through our defensive shield must not completely inundate our civil defense system.

Civil Measures

In addition to the military measures precedent to a manageable civil defense, the following civil measures are essential:

Sufficient warning must be given of an overt attack, preferably of at least an hour, to allow civil protective measures to be taken. The provision of such warning, however, may well be a military rather than a civil responsibility.

Attack with biological or chemical agents must be detected promptly and the public immediately informed of the attack.

Proper protective devices, such as gas masks and shelters, should be available. Masks appear to be the single most effective and feasible

protective device against overt biological and chemical warfare.

Every individual must know what action is expected of him in the event of attack not only by atomic weapons but also by biological, chemical, or radiological weapons, which remain "unknowns" to most civilians. As such, they tend to cause widespread speculation as to their destructiveness and to engender unreasoning fear in many people. If civilians are to react rationally, they must have adequate knowledge about the nature of these weapons and their capabilities and limitations.

Health personnel must be prepared to deal with the emergency situation; plans for utilization of health facilities must exist; and certain medical supplies must be available.

Public Health Problems

Among the civil defense problems with which public health officials will be concerned are the provision of safe water; sewage collection and disposal; garbage and refuse storage, collection, and disposal; food sanitation; control of insects and rodents; household sanitation; detection and identification of illnesses; laboratory services; and prophylactic services. Most of these are essentially local community problems.

Public Water Supply

To maintain a supply of water adequate in quantity and pressure for fire fighting and, at the same time, to make sure that water does not become a vehicle for the mass transmission of disease, will be a major civil defense problem. Any decision to introduce unpotable water into the water distribution system for fire-fighting purposes should be made on the basis of policies developed jointly by the health, water, and fire departments. The problems occasioned by contaminated water supply systems must be carefully weighed against possible losses from fire. These departments should also collaborate on the development of alternate sources of water supply and measures to protect and repair the water system.

Provision should be made for the emergency purification of water by chlorination and other methods, using portable or fixed equipment, so that medical and other civil defense services,

hospitals, welfare mass-care facilities, restaurants, householders, and other consumers will be assured of an adequate supply of potable water. The public should be advised of measures which can be used during extreme emergencies to provide themselves with small amounts of safe drinking water, but reliance should not be placed upon the householders' efforts if it is at all possible to make other arrangements. Adherence to current standard methods of water purification will negate in large part any threat of contamination with biological warfare or chemical warfare agents introduced in advance of the purification process. Special, but not insurmountable, problems will be posed by the introduction of these agents beyond the purification plant. The only present protection is either the maintenance of a high residual chlorine in the water or the introduction of chemical neutralizing agents.

Sewage

Sewage collection and sewage disposal is not as serious a civil defense problem as might at first be imagined. It is possible that radioactive materials may be carried into the sewer lines and concentrated at the sewage plant, but this is, of course, of concern primarily to sewer works operators and maintenance crews. The disruption of treatment and disposal processes is not likely to produce significant health hazards.

The principal problem will be to prevent the contamination of water and food supplies with sewage from damaged sewers. Such contamination, however, may be prevented by such measures as pumping, temporary diversion, and improvised repair. In general, the repair of water systems would take priority over the repair of sewage systems, particularly of sewage treatment plants.

Garbage and Refuse

Normal collection services may be abandoned during emergency periods, and collection equipment diverted to more urgent duties. To prevent the development of insect breeding and other nuisances, community refuse handling agencies and health departments must plan to maintain certain minimum services: collection of dead animals and highly putrescible refuse;

designation of places for emergency storage (such as vacant lots or bombed-out buildings), with provision for the control of insects, rodents, and odors; and activation of emergency landfill disposal sites to supplement or replace normal disposal facilities. These measures are particularly important in the vicinity of emergency mass-feeding centers. Householders will need to know how to store or dispose of their own refuse until temporary storage points are established or until normal services are resumed.

Food Sanitation

The civil defense problem in food sanitation is to adapt the normal services of the health department and of the food industry to the dangers which will exist in an emergency. A particularly important task will be the supervision of food preparation at mass-feeding centers. Other tasks include evaluating possible contamination of food supplies by sewage, broken glass, biological, chemical, and radiological agents, and other extraordinary contaminants; implementing arrangements for decontaminating, segregating, or destroying such supplies; and arranging for the orderly opening and closing of restaurants and other public eating establishments in accordance with civil defense emergency feeding needs. Routine inspection for contamination with biological and chemical agents of all foods being used, however, is not considered feasible.

Insect and Rodent Control

Normal control of insects and rodents is usually accomplished by mobile teams of specialists working for health departments, community mosquito control agencies, or commercial rodent and pest control operators, but only a few persons and a limited amount of equipment are involved. The civil defense job is to organize these limited facilities so that they may be readily deployed wherever they may be needed, and to train assisting personnel recruited from outside the vector control field.

Household Sanitation

Household sanitation will be crucial during any civil defense emergency, for it must be expected that many of the sanitation services

which are now taken for granted will be disrupted. One of the most serious problems will be the disposal of excreta in the event of water supply or sewerage failure, particularly for apartment dwellers and others not having access to backyard burial facilities. Two types of containers have been suggested. One is a watertight vessel for the direct collection of all human excreta. The other is a small combustible permeable container which will allow the urine to filter out, thus reducing the volume to be stored and collected. A suitable permeable container is not currently available.

Emergency Lodging

The sanitation problems of emergency lodging are essentially those discussed previously, that is, water supply, refuse disposal, toilet facilities, and the like. In addition, health authorities must establish criteria on space allocation, ventilation, lighting, and safety precautions at entries and exits.

Epidemic Intelligence

Early detection and identification of illnesses which may result from covert or overt attack with biological or chemical agents and early clarification of the methods of dissemination are extremely important in minimizing the effects of attack and alerting for future covert attacks. The principal problem will probably be in the field of biological warfare, for the victims of modern chemical warfare agents should be readily recognized. Epidemic intelligence may provide the first clue that a covert biological warfare attack has taken place.

Local health departments ordinarily investigate unusual outbreaks of disease, encourage prompt reporting of infectious diseases by physicians and hospitals, and provide laboratory services for the identification of infectious agents. All these services will be necessary for epidemic intelligence; therefore, integration of the normal peacetime functions of health departments with civil defense activities is essential. Mobile epidemiological teams may be needed to assist local health departments in carrying out epidemic intelligence activities during an emergency.

Another important aspect of epidemic intelligence is the need for emergency research dur-

ing and immediately after any overt attack so that the nature and effectiveness of the weapons used and the effectiveness of the civil defense countermeasures can be evaluated. Such evaluations may aid in saving lives in future attack. Specific, scientific teams should be assigned to obtain the necessary data.

Laboratory Services

The many laboratories in local, State, and Federal public health agencies; in medical, dental, veterinary, and other teaching institutions; and in private and commercial organizations can provide the laboratory services needed during an emergency for the preservation and restoration of normal sanitation activities, for the identification of biological warfare agents, and in some instances for the preparation of immunizing materials. Clinical laboratory services for the treatment of hospitalized and nonhospitalized patients are present in most hospitals, but these will have to be expanded greatly to deal with the large numbers of casualties expected from an overt attack. The personnel in these laboratories are, of course, familiar with basic laboratory procedures, but it is essential that special training be given in the use of instruments and techniques for dealing with the chemical agents and exotic organism that may be used. Such training is necessary not only for existing personnel but also for the many auxiliary workers who will be needed.

Prophylactic Services

Atomic disaster would increase the spread of natural communicable diseases because of the disruption of sanitation services and the inevitable crowding of people under relatively poor hygienic conditions. If biological warfare agents should also be used, the dangers of disease spread would be further increased.

The National Research Council has recommended that all persons, adults and children alike, be immunized against tetanus because of the danger of infection following burns and other injuries. The Association of State and Territorial Health Officers, because of the practical difficulties involved in such a program, prefers instead to promote the immunization of children.

The practical limitations of any immunization program at this time are recognized, but it is suggested that the immunization of children against diphtheria and whooping cough and of both children and adults against tetanus and smallpox be encouraged and that substantial quantities of these immunizing agents be stockpiled against a future emergency. These stockpiles will be needed in the event of an actual attack and might be used even before an attack if the situation becomes so critical that people become convinced of the necessity for such immunizations.

Suggestions for Action

A few suggestions for action to meet some of the public health problems have been given in connection with the discussion of these items. There remain several broad recommendations affecting both public health and medical care problems which deserve special emphasis.

Local Casualty Estimates

In estimating the number of casualties, most of the local civil defense health service planning has been concerned with the physical casualties following atomic attack. Little consideration has been given to possible casualties from bacteriological and chemical warfare agents and to psychiatric casualties from any type of attack. It is believed that metropolitan area civil defense personnel should make estimates of such casualties on the basis of local and other information. It is suggested that estimates of psychiatric casualties from a sudden catastrophic attack might be predicated on a rate of approximately 1 such casualty for each 4 to 6 physical casualties.

Strengthening Local Services

Most local civil defense health organizations are not now ready to deal effectively with a major enemy attack directly involving the civilian population, although, of course, some are better prepared than others. Many programs are lagging seriously because of a lack of personnel with medical administrative experience who can devote full time to recruiting, organizing, and training a "hard core" of regular civil defense health workers.

The civil defense health service should be developed according to a phased schedule, involving motivation, planning, development of organization, and recruiting and training of leaders and workers. Emphasis at the present time should be on the development of a "hard core" of regular civil defense health workers rather than on the recruiting of millions of volunteers. School buildings and other structures should be earmarked for possible use as temporary hospitals and first-aid stations. Ocean-going, lake, and river vessels should also be considered as possible temporary hospitals. Health departments, particularly in urban areas, should bring their epidemic intelligence services to a high degree of proficiency.

Mobile Support

A marked disparity will undoubtedly exist between the number of trained personnel and physical facilities needed to provide even minimal civil defense health services and the number available, even if all present and projected health resources are available after an attack. Furthermore, an atomic attack could destroy most of the health personnel and facilities in the target area, and biological or chemical attack on an unprepared population could destroy or incapacitate most of the health personnel even though the facilities may be spared. *Thus, people in target areas surviving such attacks may have to rely almost exclusively on medical aid from outside the target areas.*

Local hospitals and health organizations have done very little planning for the utilization of outside aid, though many of them have given considerable attention to the vital first step of self-help. Accordingly, it is believed that local, State, regional, and Federal civil defense health planners should give increased emphasis to plans for mobile support by medical and public health personnel and for the use of medical facilities at a distance from target areas. The validity of such plans must be assessed by regional test exercises.

Rehabilitation Policies

The development of sound emergency health service plans could be accelerated by establishing national policy on such questions as the extent to which individual and community med-

ical rehabilitation is to be carried out or financed by Federal, State, and local official and voluntary agencies; the relation of medical rehabilitation to other rehabilitation activities; the nature of war risk insurance, if any. Health services which make optimum provision for the smooth transition from short-term emergency actions to long-term rehabilitation activities and which assure continuity of care for the injured depends on clarifying these problems.

Utilization of Health Manpower

Much remains to be done to assure maximum effectiveness in the use of the critically short supply of professional and subprofessional health personnel in all categories. The majority of treatment activities, short of surgery, will have to be carried out by technical aids under professional supervision. Therefore, careful study of medical, nursing, and other health functions necessary during an emergency should be made to determine which of the activities usually performed by professional and subprofessional personnel can be delegated to less highly trained volunteers working under competent supervision.

Basic Principles

The purposes of civil defense health services are (a) to minimize the extent and severity of, and provide treatment for, civilian casualties caused by enemy action and (b) to maintain the health of, and provide emergency noncasualty medical service for, evacuees and other individuals deprived of their usual medical care resources.

It is imperative, however, that the normal patient-doctor relationship be reestablished at the earliest possible moment after a disaster so that the current structure for providing health services be affected as little as possible. The established patterns and long-range trends in the provision of health services should not be modified unduly by the necessity to provide emergency mass treatment. It is also imperative that continuity of medical care be maintained for each casualty during the transition between the health emergency and rehabilitation phases.

These basic principles can best be applied by utilizing to the fullest extent possible existing civilian health services in providing emergency health services.

Process for Extracting Andromedotoxin

Andromedotoxin, a pure compound with therapeutic possibilities in the treatment of hypertension, has been isolated from rhododendron leaves by a modified extraction process developed by two research groups of the National Heart Institute of the Public Health Service. The chemical structure of the drug is still unknown. Not a cure for hypertension, the compound may be useful in lowering the blood pressure in certain cases of hypertension. The compound has not been tested clinically, but trials at Emory University School of Medicine have demonstrated that it temporarily lowers blood pressure in animals. In low doses, it has a strong but brief hypotensive effect.

Special methods for extracting the material, precipitation procedures for eliminating unwanted substances, and chemical steps for purifying the compound by selective absorption were developed by the researchers.

To isolate andromedotoxin, fresh leaves of the native North America species *Rhododendron maximum* were first chopped, then boiled for an hour, and strained. In appearance, the brew changes during the extraction process from a substance resembling strong black coffee to one with the consistency of new-fallen snow. Of special interest to pharmacologists, the clumpy substance resembles the veratrum alkaloids in physiological actions, but unlike alkaloids, it contains no nitrogen.

More than 1,000 pounds of rhododendron leaves were required to make 1 ounce of the drug. They were collected by the United States Department of Agriculture in North Carolina and West Virginia. The isolation procedures were conducted at the Institute and the pharmacological work was done at Emory. Dr. Neil C. Moran reported on the research at the annual meeting of the American Society for Pharmacology and Experimental Therapeutics at New Haven, Conn., September 7, 1953.

Water, Sewage, and Industrial Waste Research Trends and Needs

By ALFRED H. WIETERS, M.S., and LEONARD B. DWORSKY, B.S.

ALTHOUGH the problems of sanitation are as old as man, scientific research in the water and sewage field is relatively new. It is a field in which the States have historically taken a leading part. The establishment of the Lawrence Experiment Station as a part of the Massachusetts Health Department in 1886 marked the beginning of the science of sewage disposal in the United States. Since those early days, similar experimental work has been undertaken by many of the other States.

It is appropriate that the States should continue to have a major role in this field. They have the knowledge of the factors in their own

environments—climate, health, natural resources, economic conditions, industrial and other relationships—that is necessary for the most effective research on problems relating to their own individual concerns. In addition the States are the best laboratories for trying and testing new sanitation developments, prior to adoption on a broader or even national scale.

Volume of Research

A complete listing of current research projects is not available. However, on the basis of information assembled from several sources (1-3), it appears that between 150 and 200 projects currently in progress in the States directly concern water supply, sewage treatment, and pollution control and about 100 additional projects deal specifically with industrial waste. Most of these are being conducted by college and university laboratories, and the rest by State organizations, technical associations, or private research institutions. Some of the projects are being supported in part by Federal grants, principally from the Public Health Service and the Atomic Energy Commission, with a few from the United States Bureau of Mines, United States Geological Survey, United States Army, and others. Many additional investigations on industrial wastes are, of course, being conducted by individual industries.

Even on the basis of admittedly incomplete

Mr. Wieters, since 1948 assistant chief of the Division of Water Pollution Control of the Public Health Service, was director of the division of sanitary engineering of the Iowa State Health Department from 1926 to 1946. Mr. Dworsky was a sanitary engineer with the Illinois Department of Public Health and Cook County Department of Public Health from 1936 to 1941. After service in the Army Sanitary Corps, 1941-46, he came to the Public Health Service and since 1948 has been with the Division of Water Pollution Control as chief, reports and education branch.

This paper is based on material presented by Mr. Wieters before the Texas Water and Sewage Research Foundation at Austin on November 10, 1952.

information, it is apparent that in more than three-fourths of the States some research activity is under way in either the water and sewage or the industrial waste field. The extent of this activity ranges from 1 project to more than 25 separate studies in a single State.

The Federal Government has been an important factor in certain broad areas of research, either by conducting investigations in its own laboratories or by contributing largely to their support in the facilities of universities, States, industries, or private institutions. Such studies include those related to military developments and electronics; those concerned with the public domain, mineral resources, agriculture; a considerable part of health research; and other broadly based, long-term investigations in the purely theoretical area. The advances in fundamental knowledge stemming from basic research makes possible the applied and developmental progress in problem areas.

Public Health Research

In the public health field, systematic and continued scientific investigation as a recognized function of the Public Health Service began at the turn of the century, although some research was conducted as early as 1891 in the somewhat makeshift facilities of the Hygienic Laboratory. In 1901 Congress provided for the erection of a laboratory "for the investigation of infectious and contagious diseases and matters pertaining to the public health," and a division of scientific research was organized in the Service.

From the very beginning, attention was given to the relation of stream pollution to disease. It was not until 1910, however, that there was an organized, large-scale investigation in this field. At that time a study was made in the Great Lakes region of the relation of polluted water supplies to typhoid fever. This study was followed in 1912 by a pollution survey of the Missouri River. A short time later several temporary laboratories were established for field investigations, one of them at Cincinnati, and work on a plan for comprehensive stream pollution investigations was begun (4).

The Cincinnati laboratory, now the Environmental Health Center, has since been the focus for the Service's environmental research. Consistently, through the years, the investigations of the center have been those having general, rather than local, application, and those requiring the kind of continuous or extensive studies not likely to be undertaken by private agencies, or by State and municipal organizations.

Work currently in progress in water pollution and related areas includes development and evaluation of analytical techniques for both organic and inorganic materials; studies of persistence of particular organic compounds in water; application of biological oxidation processes to waste purification; studies of industrial waste sources, characteristics, and corrective measures; inventory surveys on pollution of water resources; development of biological methods for determining the severity and extent of pollution; studies of toxicity of water pollutants to aquatic life; development of bioassay methods and their application to pollution control; development of methods for control of organisms responsible for tastes and odors in water supplies; and studies of pollution and purification of shellfish in aquatic environments. Time and time again, these studies have resulted in significant developments that are now being widely used.

The Need for Basic Research

The importance of basic research to the Nation's security and continued prosperity was emphasized by experience during both World Wars. Since the turn of the century, the country has made rapid and continuous technological progress, advancing from an agricultural Nation to a highly industrialized world power. In many fields, however, technological developments were based principally on the basic and fundamental discoveries of the scientists of other nations, and our contribution was mainly applied and developmental. When the free flow of scientific information from Europe was cut off, we faced a serious deficiency in facilities and capacity for basic research.

Recognition of the inadequacy of this country's research programs led the President, in 1946, to appoint a Scientific Research Board to

review the current national situation and recommend a course of action which would insure that the scientific personnel, training, and research facilities of the Nation would be used most effectively in the national interest.

The board's report in 1947 indicated that the Nation was then spending \$1.1 billion annually for research. Only about 10 percent of that amount was for basic research. The board recommended that by 1957 the annual rate of total research expenditures be doubled, of health research, tripled, and of basic research, quadrupled. It further recommended the establishment of a National Science Foundation to establish research policy for the Nation and to administer Federal grants in support of basic research.

Such a foundation was established by the Congress on May 10, 1950. Subsequently, the foundation has reported that in 1951 the Nation spent an estimated \$2.5 billion for research and development (5), and in 1952, about \$3 billion (6). A preliminary report issued jointly by the Departments of Defense and Labor set the 1952 national outlay for scientific research and development at more than \$3.5 billion (7). Thus the Scientific Research Board's 1957 goal for total research has already been reached and passed. The unexpectedly rapid acceleration was due in part, of course, to the great increase in projects having military significance, stimulated by the defense buildup. A contributing factor has also been industry's growing awareness of the important role of research in expanding productivity and markets. To an increasing degree, industries are devoting substantial portions of their budgets to research and product development, such expenditures amounting in 1951 to \$1.2 billion. In view of the high returns now recognized as resulting from these outlays, the trend toward greater emphasis on industrial research is expected to continue (8). The cost of research conducted by the industries included in the Defense-Labor survey referred to above was reported as 2 percent of sales.

Health Research

Although the rate of increase in health research expenditures has been considerably less than that for total research expenditures, prog-

ress has been made toward the 1957 goal of \$300 million recommended by the Scientific Research Board. The latest published estimates indicate a total of \$181.2 million for 1951, an increase of about 60 percent over the \$115 million reported by the board in 1947 (9). The national totals for health research expenditures have not been broken down into subcategories which would permit a similar determination of the increase in water and sewage research. A committee exploring research needs in the somewhat broader area of environmental health reported in 1952 that it roughly estimated 1951 expenditures for research in that field at less than 10 percent of total health research (10).

An analysis of Public Health Service research expenditures (slightly less than 20 percent of the national total for health research), while not entirely representative of the overall situation, is meaningful. In 1952, about 2 percent of the total funds expended under Public Health Service research grants, and something less than 5 percent of the funds expended for direct research by Public Health Service staff, were allotted to projects in the environmental health field. These included, in addition to projects related to water treatment, water quality control, and water pollution, those covering various aspects of occupational health, air pollution, milk and food sanitation, radiological health, and such. In the 5-year period from 1948 through 1952, the number of environmental health grants increased about 40 percent and the amount of expenditures for such projects about 30 percent, as compared with increases of about 85 percent and 90 percent, respectively, in total public health research grants.

The report of a recent survey limited to projects dealing with treatment and disposal of sewage and industrial wastes and water pollution indicates that in the decade 1943 to 1953 the number of such projects increased from 128 to 148, about 16 percent. However the 1953 survey covered only the member institutions of the Engineering College Research Council, leaving for a later survey the projects being conducted directly by State health departments, interstate and intrastate agencies, industries, equipment manufacturers, municipal plants, trade associations, and others (3). Undoubt-

edly inclusion of those projects would materially raise the percentage of increase for the 10-year period, although it must be assumed, from the report of the earlier survey, that it, too, was incomplete.

Industrial Wastes

With respect to the problem of pollution caused by industrial wastes, specific responsibility rests upon the particular industries and plants that create the wastes. The Water Pollution Control Act (11) does, however, authorize the Service to support and aid research to devise and perfect methods of treatment of industrial wastes, and otherwise to help in solving the problem.

Industry has undertaken a considerable amount of research, over the years, looking toward the solution of specific industrial waste problems. Recognizing the need for concerted action, several branches of industry volunteered early in 1950 to form a national committee as a means of appraising and coordinating the work under way, promoting further research and development, and stimulating the adoption of known practical pollution abatement methods by all segments of industry. The National Technical Task Committee on Industrial Wastes, representing 36 major industrial categories, was organized in May of that year at the invitation of the Surgeon General.

The Service works closely with the committee, providing technical and consultative assistance and serving as a clearing house for the interchange of technical information. As one phase of this cooperative work, the Service has compiled and maintains on punch cards an up-to-date inventory of industrial waste treatment methods, problems, and current and planned research projects. The initial information for this inventory was provided by the member industries of the committee, which supply additional items as they develop, and has been supplemented by abstracts of pertinent articles and reports appearing in technical journals. The assembled information is made available to the committee through distribution of sets of the punch cards to each member.

Obviously, the coordinated research and pooling of information available from this

group, representing practically the entire industrial organization of the country, is of tremendous value.

Future Research Needs

The foregoing background is presented for the consideration of future research needs in the water, sewage, and industrial wastes fields. In determining specific research areas that most critically need attention, both now and in the future, special consideration must be given to the impact on water and sewage problems of such factors as: the expansion of industry; the development of new products; the depletion of our natural resources; the growth of population; increased urbanization; rising standards of living; increases in water requirements; increase in volume of wastes; the broadening concept of water resources development.

Industrial Developments

Perhaps the greatest number and variety of problems stem from expanding industry. Since 1900, production has increased more than seven times. Over half of that increase has taken place in the past decade. The President's Materials Policy Commission predicts that between 1950 and 1975 there will be another 100 percent increase (12). As the growing industrial machine has consumed raw materials at faster and faster rates, the threat of depletion of the less plentiful natural resources has furnished incentive for the development of many new materials from the abundant supplies of coal, air, and water—materials such as plastics, synthetic fibers, insecticides, and weedkillers. Production of these materials is adding quantities of wastes to our streams. As yet, there is no basis for even estimating what the volume of these wastes will be. The Materials Policy Commission reports that it is impossible to project production of those new materials as for established products, since these recent and continually growing industries have not yet found their stable place in the economy. Tentative estimates indicate that the production of synthetic fibers, such as nylon, orlon, and dacron, will increase from slightly more than 150 million pounds in 1950 to about 4 billion pounds in 1975; production of insecticides is expected to

double and of weedkillers to triple in that period; 1975 production of plastics is estimated at 9 billion pounds as compared with 2.28 billion in 1950; detergents may increase from 1.66 million pounds to possibly 4 billion by 1975 (13, 14).

In addition to the problem of manufacturing wastes, there is, for some of these products, the question of the effects their use will have on the basic elements of our environment. What will they do to the air and to the water when they are washed into the streams? For example, we do not yet know the extent to which present public water supply treatment methods will be effective against the chemicals now being placed in our streams as a result of use of new insecticides and weedkillers. The recent rapid development of chemical-producing industries in concentrated areas, as for example, along the east coast of Texas, has created air pollution and other difficulties that must be speedily overcome if the benefits of such growth are to outweigh the penalties.

The chemical industry as a whole is progressive, forward-looking, and conscious of its responsibilities to the communities in which it operates. It has spent large sums of money on research and equipment for preventing pollution of both air and water and there is good reason to expect that, as new problems arise, answers will be found.

Other industries, too, are becoming increasingly aware of the need for conserving water quality in order to insure an adequate future supply for their needs. They are also becoming more conscious of their public responsibility for disposing of the wastes they create in such a way that they will not damage these resources.

Population Growth

This country's population has doubled during the past half century. Current estimates indicate that by 1975 it will approach the 200 million mark. Along with this growth, there has been a continued trend toward concentration of population in urban centers. Sixty-five percent of the population is now urban, 35 percent rural. This trend can be expected to continue and the problems are expected to intensify as the Nation's industrial machine expands.

The problem of disposal or utilization of the

added volumes of both industrial and municipal wastes is in itself a staggering one. When the demands that will be made upon our water resources in the years immediately ahead are considered it is clear that the Nation cannot afford the inevitable reduction in usable water supplies that would result from discharge of these wastes, untreated, into the streams. The Nation's water requirements in 1975 are expected to be 90 percent greater than in 1950—almost double. Industry's needs alone may increase 170 percent, from 80 billion gallons per day to 215 billion gallons. Municipal and rural needs should increase 50 percent, partly due to increased population and partly to intensified use of modern appliances requiring water for operation—dishwashers, garbage disposals, automatic laundry equipment, and air conditioning.

These estimates are an indication of what the future will demand. The fact that there are many areas, even now, where the problem of adequate water supplies is becoming critical is forewarning that solutions must be found while there is yet time.

Most Needed Areas of Research

There are several areas of research that are obviously of major and primary importance.

New techniques must be developed for determining the amounts and kinds of pollution present in the streams, and the effects of such pollution on the receiving waters. With present analytical methods it is necessary to be satisfied with something less than the best determinations on the growing volume of wastes, many of which are the products of raw materials and processes that are outside our present experience.

Better yardsticks must be established for water quality objectives. Until more precise quality requirements are agreed upon for each of the various water uses—bathing water quality, irrigation, livestock, public water supply, industrial, and the others—we are restricted in our ability to determine which of those uses are attainable in each of the individual river basin areas and can thus be adopted as goals in developing comprehensive water pollution control programs.

Cheaper sewage treatment methods must be developed. There have been relatively few basic changes in sewage treatment methods over the years, although some attempts have been made to perfect and refine them. While the methods in use have been reasonably effective, there is an obligation to the public to reduce the cost of this public service if it is possible to do so. Scientific knowledge has made great advances since the present treatment methods were developed. Some of those advances should provide the basic principles from which could be developed better, quicker, and cheaper sewage treatment processes.

Methods for treating new types of industrial wastes must be developed. As stated earlier, this is basically the responsibility of industry itself. Those who develop the new manufacturing processes and products are the ones best fitted to solve the waste problems accompanying such development. For that task principal reliance must be placed on industry itself. Industry is best equipped also to look beyond the wastes and investigate the prospects of utilization, either by reclaiming raw materials or by developing byproducts.

Persons trained for this work are in short supply. The Nation is not producing enough technical personnel to satisfy its growing requirements. A solution to the problem of conserving and making full use not only of trained personnel but of laboratory facilities may be found in the more extensive use of regional, nonprofit, independent research organizations. Such agencies can provide corps of trained researchers who can give service to State governments, to industry, and to others interested in sponsoring investigations in various fields. They are able to undertake jointly sponsored research leading to the solution of many of the common problems that face industries and local governments in areas where rapid development is taking place. They can act as a clearing house for new scientific information in such areas.

A recent summary of 1950-53 growth of 7 independent research organizations (which together account for more than 1 percent of the Nation's total research outlay) gives evidence of the increasing use being made of this type of organization. Collectively these 7 regional

centers have doubled their business volume in less than 4 years (15).

There is need for integration and coordination of research studies and findings. Research organizations and workers must be constantly aware of studies under way in other areas that might produce results affecting their own investigations. As an illustration, consider the work in progress on removal of salt from sea water in order to open up new water supply sources. Thus far, no economically feasible method has been perfected, but the project has progressed beyond the merely theoretical stage. In a law passed in 1952 (16), the Department of the Interior was directed to further pursue the investigations. Excessive processing cost is an important hurdle in attaining the objective. Closely allied studies are concerned with the extraction of usable minerals from the ocean. In the search for new sources of rare materials, attention has turned to sea water, sea life, and the ocean bottom. Practical methods have already been found for extracting some of the wealth that we now know the ocean holds. For example, bromine and magnesium are being economically recovered from sea water. The development of economical recovery techniques will add many others. All of these endeavors will move more rapidly if the researchers in each field keep informed of developments in the others. Every usable material that can be added to the list of those obtainable from the sea, every feasible combination of processes for their extraction, will lessen the cost for each and bring closer the possibility of economical operation.

Multiple-purpose use. We need to project our vision beyond its horizons, which perhaps have been too limited by our concentration over the years on the narrowly defined public health aspects of water and the relation of waste treatment to public health per se. We need to have a deeper appreciation of the multiple-purpose concept of water use, and to apply that concept to our work. From a long-term view, this is a relatively new concept. It has been an outgrowth of basic legislation developed over the past half century—the Reclamation Act of 1902; the Tennessee Valley Authority Act, adopted in 1933; the Flood Control Law of 1936; the Water Pollution Control Act of 1948.

This kind of development of our water resources was foreseen by Theodore Roosevelt when he wrote (17) :

Every stream should be used to its utmost. No stream can be so used unless such use is planned far in advance. When such plans are met, we shall find that, instead of interfering, one use can often be made to assist another. Each river system, from its headwaters in the forest to its mouth on the coast, is a single unit and should be treated as such.

Under this concept, the water problem takes on a new perspective. Programs encompass entire basins; all water uses—domestic, industrial, agricultural, recreational, fish and aquatic life, waste disposal—are factors in a total regional planning process rather than separate entities related only to a particular water or sewage plant. Under this concept our sights are raised past the boundaries of the communities which those plants serve.

In actual practice, the States are attaining this broadened perspective through the increasing use of regional councils and interstate compact groups for joint consideration and solution of their common water problems.

As plans are developed on broad basin areas, the water needs of industry, of the population, of agriculture, and of other users must be compared. The benefits from those uses must be weighed. The possible advantages of changing existing priorities—as between industrial, agricultural, and other uses—must be given careful consideration. If the full benefits of river basin development are to be realized, water quality must be conserved.

Adequate basic information is essential to meet the growing need for developing the Nation's water resources in a way that will best serve all the people. We need more rainfall and stream flow records, particularly low flow records; we need additional data on the physical, chemical, and bacteriological characteristics of the raw water in our streams. We need up-to-date facts on the economics behind the various water uses.

Development of better procedures for assuring that research findings are utilized is an

urgency. Too often, the active interest of those who have completed a research study ends with their report of findings. There should be an additional step in the research process, a following-through by those actually producing the findings, to assure that new knowledge is channeled to those who need it. This requires the development of closer relationships between those engaged in research of a physical nature and those working in the social and political science fields. In the area of research dealing with water and sewage, for example, there should be cooperation with agencies such as the bureaus of governmental research in universities, and the organizations providing service to governmental agencies—the International Association of City Managers, the Council of State Governments, and the like. The use of periodicals in the political science, social science, and economic fields, in addition to those in the sanitary engineering and public health fields, as a means of communicating certain kinds of research findings might aid in the development of such relationships.

Careful interpretation of findings and their presentation in a way that will permit their most effective use at the operating levels are also important elements in this followup procedure. The important point is that in order to get the maximum value from research expenditures, we must not only take responsibility for actually doing research, but must also make certain that the knowledge provided by research reaches those who can make effective use of it.

Dr. Meister Wins 1954 Chemistry Award

Dr. Alton Meister, head of the clinical biochemical research section, laboratory of biochemistry at the National Cancer Institute, was selected to receive the 1954 Paul-Lewis Laboratories award in enzyme chemistry. The award, consisting of a gold medal and \$1,000, is given each year by the American Chemical Society to the outstanding American enzyme chemist under the age of 40.

Dr. Meister, who is 31, won the award for discovering the mechanisms by which normal tissues and cancer tissues cause the exchange of chemical groups between amino acids and the breakdown products of sugar and for discovering that vitamin B₆ is necessary in this exchange. Glutamine, an important compound present in almost all tissues, was found to be the key substance in many of these reactions. In the course of his experiments, a number of new compounds called "keto acids" were isolated in crystalline form for the first time, and the way in which the body converts them into amino acids was determined. These studies may be helpful in explaining the growth processes of cancer cells.

Previous Paul-Lewis awards were won in 1953, 1952, and 1951 by Drs. Earl R. Stadtman, Bernard L. Horecker, and Arthur Kornberg, all of the National Institutes of Health, Public Health Service, Bethesda, Md.

Environmental Health in a Rural Economy

By MARK D. HOLLIS, C.E.

PROGRESS in environmental health in rural areas has lagged behind improvements in urban living. Rural sanitation, though it has advanced considerably in recent years, has lagged behind other forms of material progress even in rural areas, and, in certain respects, the rural environment in the past 10 years has deteriorated. Such deterioration is observed not only in the lack of maintenance of originally satisfactory installations, it is found also in new installations in fringe urban areas where, for example, septic tanks have been employed under unsuitable conditions.

Public health in the city is affected by rural health. The food of the population as a whole depends on the productive efforts of a small rural minority (1). In view of its economic importance and in view of the tendency of rural youth to move to cities, the rural population's health should be at least as good as the health of urban dwellers. There is a prospect that the productive powers of the rural population must be increased by all means possible to feed a growing population (2). Moreover, in an age of automobiles and planes, the communication of disease between rural and urban areas is swift: it is folly to expose any part of

the population unnecessarily to channels of infection (3). The lack of rural sanitation imperils not only the country dweller but also the many millions from the city who visit rural recreational areas.

Sanitation as an Investment

The speed and direction of change in our times has not spared the rural economy. In older agrarian societies where the life cycle seemed to repeat itself from season to season, traditional customs and techniques were seldom questioned. But modern technology has stepped up the tempo of every isolated farm and quiet hamlet. Rural life has grown so much more complex that it becomes necessary not only to meet present sanitation needs but also to prepare to meet needs of the future. At present, we think of the rural dwellers who come to the city. For the future, we may think of the possibility of a dispersion from cities to rural areas as a technique of civil defense (4).

The emphasis on economic factors in environmental health is prompted by knowledge that vital statistics have so much to do with earning a living (5). We work to produce the essentials of life which make it possible for us to work. At the same time, improvements in health do not necessarily increase productivity; nor does every economic gain necessarily contribute to health. The relation between health and economics is not simple. While it may be assumed generally that every investment in health is returned many times over to the economy, it is practical to ask how to invest money in health

Assistant Surgeon General Hollis, chief engineer of the Public Health Service, used the data in this paper in July 1953 in discussions with the WHO Expert Committee on Environmental Sanitation, in Geneva. This paper deals with conditions in the United States only.

so as to secure the greatest return per dollar. The value of the return itself must be gauged not only by morbidity statistics but also by statistics indicating a change in levels of consumption, productivity, and social welfare. To determine whether the gain from rural sanitation is worth the cost in each area is not to question whether it pays to save a life. The question is how, with available resources, investment in rural sanitation can secure a satisfactory return in the abundance and richness of human life.

Rural Attitudes

About a third of the population is rural. A sixth of the Nation live on farms: these feed the lot of us and some abroad, too. About 30 million other rural Americans live in villages of less than 2,500 or in even more isolated circumstances. They include loggers, fishermen, trappers, miners, retired elders, and commuters. Half of the rural population lives in the south, where a fourth of the farm families are non-white. The total rural population exceeds 55 million.

Obviously, the needs of the rural population vary from house to house. Also, the operations to finance and administer sanitation programs for this population are bound to vary. The necessity for tailoring sanitation operations to peculiar local needs places the main responsibility upon local authorities, and often on the individual family.

Government is ordinarily held responsible for financing public health services in the city. This is not so in the country. Sanitation of food and premises is clearly a public problem in the village and in other rural centers such as the school, church, and grange or community hall. But in most rural areas in the United States, sanitation is ordinarily regarded as an individual or private concern, even though many individual rural families cannot finance sanitation by themselves. If there is the will to bring rural demands for environmental improvement into balance with the demand for cars and electricity, however, the economic devices that provide cars, telephones, and power are capable of financing pipes and drains as well.

In the city, the danger of contagion has created awareness of community responsibility. In rural areas, the danger of contagion is less apparent. It is recognized mainly in the enforcement of sanitation on dairy farms, in the effort to protect the safety of fluid milk produced for the urban market. Hygienic milk production is probably the heaviest single contribution of its kind to rural environmental health in the United States. Tests of village water supplies by State and county health departments may rank next.

Factors in the Lag

Three major factors in the lag in rural sanitation are the relatively high cost of water and sewerage systems for isolated structures, the usual necessity to finance each installation individually at relatively high rates, and the absence in many rural areas of a strong public health authority. These factors have less force in the village than on the farm.

Isolation, an important factor in protecting the health of the rural family, especially the farm family, also imposes penalties, especially penalties of a social nature. For example, among farm families with an annual income of more than \$10,000, it is found that 1 in 8 lives without running water in the house, and 1 in 30 lives in a dilapidated dwelling. Presumably, in an urban environment, these same families, stimulated by the example of their neighbors, would be much more likely to occupy homes reflecting their economic status.

The great majority of farm families, however, are not usually in a position to finance environmental improvements even at modest interest rates. To relieve their situation, there must be a narrowing of the gap between costs and capacity to pay, as a consequence of higher earnings, technological progress, or favorable financial devices. Most nonfarm rural families are only slightly better off. Environmental health services may be contributory to economic gains in rural areas, but first there must be economic devices to improve the rural environment.

Such devices have in fact contributed to rural improvements, including lighting, refrigeration, cleaning, smokeless cooking, and

milk sterilization. According to the United States Department of Agriculture index, American farm living improved 25 percent from 1940 to 1945. The improvement was 37 percent in the southeast. This index grades living levels on the farm according to the value of its products and the presence of an automobile, electricity, and a telephone. All these factors are important in the economy and welfare of the farm. The important factor of water does not figure directly in the index, although health levels are affected by the simple availability of water. Both the living level and the productivity of the farm family depend on easy access to water for such purposes as washing, bathing, irrigation, cooling facilities, and a water-carriage disposal system.

Health and Health Facilities

Much of the recent literature on rural health touches only lightly on the environment. There has been a tendency to assume that the books on rural sanitation were closed with the decline of interest in hookworm. Even malaria control in rural areas is regarded by a few as a closed chapter. It has been more fashionable to speak of rural health wholly in terms of clinics, physicians, and nurses. Important as personal health services are, however, they do not reduce the value to family health of running water in the house, safe shelter, proper waste disposal, and protection against vectors of disease. Such environmental factors, covered here in the comprehensive term "sanitation," can contribute directly to rural health and indirectly to rural personal health services. If rural areas gain in health and productivity through improved sanitation, they will be less in need of other health services, and they will also more readily obtain and afford the other services they should have—nurses, physicians, and clinics.

The more rural the area, the fewer the health personnel, services, and facilities are in proportion to the population. At present there are public health organizations in approximately 1,600 of the 3,071 counties in the Nation. Most of these provide some service to rural areas. The counties that are not organized for direct full-time health services hold less than a fourth of the national population, but these counties

are predominantly rural. They contain 30 percent of the national rural population.

Some explanation for the slow trend in farm sanitation may be found in the studies which determined that village residents suffer more enteric infections than farmers (5). These studies suggest that the need for sanitation is less urgent on the farm.

The negative trend in village sanitation is laid to the unplanned construction of new homes without regard to the needs for water or waste disposal. About 40 percent of the new homes built in recent years are served with septic tanks rather than with sewer lines (6). In addition to the burden of maintenance, such installations require a proper regard for the suitability of the soil, the water table, and the density of the population.

In the past, the rural environment has been considered more healthful than the city, an assumption which must be qualified today. Relative healthfulness of environment depends on what places and conditions are compared. Even on the fundamental issue of the quality of the atmosphere, many a rural dweller is more exposed to dust, fungi, or pollen than an urban dweller who works and sleeps in an atmosphere which is filtered, humidified, and cooled or warmed to order.

Although the romantic appeal of the rural environment is strong, it is tempered by epidemiology. In 1900, the registered death rate among farmers was only half the urban death rate (7). Since then, however, living conditions in the city have been improved, and there has been a strong movement of relatively healthy and vigorous young people from rural to urban residence. Consequently, the death rates registered in rural and urban areas today are about equal. Death rates for mothers and infants are higher in rural areas than in cities. As to the death rates from enteric diseases, these are associated with a lack of water-carriage sewage facilities, a lack that is common in rural areas. Recently, in one county, the death rate from dysentery and diarrhea was 169.3 per 100,000, in contrast with a national average of 5.9 (8). This range suggests how sanitation may affect rural health. Hookworm in certain rural areas is found in more than half the population. The simple availability of running water for

convenient washing of the person has a relation to health that is so obvious it is readily overlooked.

Sanitation in the broad sense applies to all facilities and practices that concern public health, and, for this reason, the records on accidental injury are pertinent. Opportunities for serious injury on farms seem greater than in cities; disabling conditions among farm workers are one and one-half times greater than among industrial workers. Accidents on farms kill 14,500 and injure an additional 1.3 million yearly (9). Although concern with accident prevention in rural areas has activated the United States Department of Agriculture, manufacturers of farm machinery, distributors of electrical power and equipment, farm youth organizations, the National Safety Council, and various rural educational leaders, the accident problem is not appreciably controlled. At the University of Michigan School of Public Health a comprehensive survey of accident experience among the population of Washtenaw County, conducted in 1951-52, revealed the home accident injury frequency of urban dwellers to be 5 per 100, as compared with 11 per 100 for rural dwellers.

Physical Sanitation Needs

It is difficult to appraise the educational and physical needs of rural sanitation. An inventory of health facilities prepared by the Public Health Service in 1947 estimated that rural physical sanitation needs included repairs to existing water supplies or development of new supplies, chiefly wells, for more than 6 million homes where facilities were either lacking or insanitary. More than 7 million homes required improved sewage disposal. In terms of the affected population, more than 27 million people in rural areas needed new or improved water supplies, and 33 million had unsatisfactory sewage disposal facilities. There was a measurable difference between rural and urban areas in the quality of the water supply.

In 1950, piped running water inside the home was available in 96.4 percent of urban dwellings and in 42.7 percent of farm dwellings. Piped water was running in 68 percent of the rural nonfarm dwellings. In round numbers,

Housing facilities

Condition	Percentages of occupied ¹ dwelling units		
	Urban	Rural non-farm	Farm
Dilapidated ²	6. 5	13. 4	19. 5
No running water in or outside the home	1. 7	28. 6	54. 6
Outside toilets	6. 8	41. 4	65. 6
Structure more than 30 years old	46. 4	39. 0	53. 4
Noncentral heat	35. 9	67. 9	80. 7
Wood cookstove	2. 4	15. 4	38. 7
Kerosene cookstove	4. 8	11. 6	8. 9

No kitchen sink	5. 3	26. 5	45. 2

¹ 42.5 million occupied dwelling units.

² A dwelling unit is classified as dilapidated when it has serious deficiencies, is run down or neglected, or is of inadequate original construction, so that the dwelling unit does not provide adequate shelter or protection against the elements or it endangers the safety of the occupants. Dilapidated dwelling units are so classified because of deterioration, as evidenced by the presence of one or more critical deficiencies or a combination of minor deficiencies, or because of inadequate original construction, such that they should be torn down, extensively repaired, or rebuilt.

SOURCE: U. S. Department of Commerce Census of Housing, 1950.

pipd water was lacking in 1.1 million urban dwellings, in 3.1 million rural nonfarm dwellings, and in 3.6 million farm dwellings.

Rural homes are more crowded than urban homes. In 1950, the percentage of dwellings with more than 1.5 persons per room was 10.2 on the farms, 8.6 in rural nonfarm dwellings, and 4.7 in urban dwellings. The relation of crowding to contact diseases, such as tuberculosis and pneumonia, has been revealed in many studies, including the National Health Survey of 1936.

Comparisons in housing facilities offer further grounds for reflection upon the differences between urban and rural health (see table). The heating and cooking facilities indicate the relative extent of fire hazards. Other hazards to safety are suggested by the degree of dilapidation and age. The icebox figures may have significance for nutrition and food poisoning.

And the nature of the water and toilet facilities may be indicators of the extent of enteric infections.

It seems apparent that rural health is poorer than it should be. Medical surveys have found the rural population relatively high in incidence of brucellosis, septic throat, enteric disorders, and insectborne disease (10).

The Rural Economy

Rural life is being transformed by population growth, by decentralization of industry, by modern communications, and by a broadening desire for the security that is attached to a piece of land. The farm economy also has been transformed by a series of strong markets, advances in agrobiolgy, electrified communication and mechanization, and a high degree of specialization suitable to given locations and markets.

According to the 1950 census of agriculture, there are more than 5 million farms. This number includes cattle ranches, groves, dairies, greenhouses, apiaries, mushroom cellars, and cranberry bogs. Nearly a third of these farms are part-time or residential farms whose occupants do not contribute materially to commercial agriculture. More than two-thirds of the operators had other income amounting to more than receipts from farm produce sales.

Of the commercial farms, more than a fourth specialize in field crops. Less than one-seventh of the commercial farms are classified as "general" farms.

Crop specialization influences the size of farms, although the wealth and enterprise of the owner, the dictates of geography and climate, and such legal provisions as those in the homestead or reclamation laws are also factors in determining farm size. A wheat farm, for example, takes more acreage than a pecan grove. Although the average size of an American farm is 215 acres, nearly 3 farms in 5 (56 percent) are smaller than 100 acres; 2 in 5 (36.5 percent) are under 50 acres. Only 5.7 percent have more than 500 acres, and most of these are in 17 western States.

The foregoing figures merely hint at variable situations to be met in a rural sanitation program. The following facts may indicate how

conditions of tenure, income, wealth, and social status influence the opportunities for sanitation.

The Virtue of Ownership

The amount of money invested in a farm, or its capital value, is bound to affect a banker's judgment as to the desirability of investing additional funds in sanitation. There is distinctly a heavier investment in farms operated by owners than in farms operated by tenants. According to the 1952 survey of consumer finances published by the Federal Reserve Board, 69 percent of the owner-operated farms were valued above \$10,000. The corresponding figure among farms operated by tenants, managers, or sharecroppers was 22 percent. At the other end of the scale, only 1 percent of the owner-operated farms but 59 percent of the non-owner-operated farms were valued below \$2,500. These valuations include land, buildings, machines, and inventory.

Although nearly 1.5 million farms in 1950 were operated by tenants or sharecroppers, the trend in American farming since 1930 has been away from tenancy and toward ownership. The percentage of farms operated by the owners has increased since 1930 from 56 to 72 in 1950. The percentage of dwellings occupied by owners in 1950 was 66 on farms and 63 in rural non-farm units. Quite a variety of farm credit programs have assisted tenants in becoming farm owners and have contributed to improvement of rural sanitation. However, the differences between sanitation facilities of owned and rented homes are less pronounced than differences related to farm value, income, location, or ethnic factors.

The relationship of tenure to dilapidation is obvious. Of 5,721,000 occupied rural farm dwellings reported in 1950, nearly 4 million were owner-occupied, and 2 million were rented. About a fourth of the tenant homes were dilapidated (see table). Most of these lacked running water. About 12 percent of the owner-occupied farm homes were dilapidated as compared with 17 percent for all occupied farm dwellings. Of the farm tenant homes in good condition, almost half were lacking in running water. Rented farm homes were more crowded than homes occupied by the owners.

Capacity to Pay

Farm income is probably the best indicator of the capacity to pay for sanitation. In 1949, by prewar standards a prosperous year, 3 out of 5 farm families reported net cash income of less than \$2,000. The median farm income of \$1,730 contrasts with \$2,560 for the rural nonfarm family and \$3,430 for the urban family in that year, even though it does not include any allowance for noncash income in the form of food and shelter provided on the farm. The maximum net cash income on nearly a third of American farms in 1946, also a prosperous year, was less than \$750.

Even when off-farm income is combined with farm income, including noncash income, it appears that in 1946 two-thirds of the farms accounted for about 92 percent of the farm family income from all sources. Ten percent of the farm families obtained 40 percent of the total income. The capacity to pay for sanitation on an individual basis was most restricted among that third of the farm families which share only 8 percent of the farm income.

Of the farm families with incomes of less than \$1,000, according to Census Bureau calculations of 1950, almost one-third lived in dilapidated homes. Two-thirds of the non-dilapidated homes in this income group lacked running water, and more than nine-tenths of the dilapidated homes occupied by this group lacked running water. Conditions were only a little better in the group, almost as large, with incomes from \$1,000 to \$2,000. These families with incomes below \$2,000 compose the majority of the farm population. Even if it is assumed that the extent of poverty in rural areas has been overstated, as it may have been, the maximum net cash income of the less prosperous farmers provides no great surplus to invest in the costs and charges described below for environmental facilities.

Ethnic Factors

Ethnic and social factors also have a bearing on the sanitation of rural dwellings. Such factors create particularly acute problems for a high proportion of nonwhite Americans, including native American tribes (17), and for

about a million migratory workers (12). The migrants' problem is particularly difficult because of their transient residence. They assume living expenses not ordinary in a settled community, and, because of temporary residence, they are unable to gain eligibility for local welfare and health services.

While housing generally has become less crowded in the period from 1940 to 1950, for the nonwhite farm population the number of persons per dwelling actually increased. More than 80 percent of the dwellings of the rural nonwhite population have outside toilets, and more than 40 percent lack running water. No toilets at all are found on the premises of 13.7 percent of the nonwhite farm population as compared to 6.4 percent for the white farm population. To report that sanitation in a given ethnic group is below average, however, does not suggest that the aspirations and potential achievements of this group may not be as high as any other.

Sanitation Costs

Costs of sanitation, in terms of out-of-pocket charges, must be recalculated for each separate project. The following figures give merely a rough idea of their probable magnitude.

In 1947, the Public Health Service estimated per-capita costs for provision of community water facilities in towns of less than 1,000 would range from \$35 to \$58, and sewage disposal systems would cost a bit more than \$60 in such areas. The cost of installing needed minimum individual rural sanitation facilities, such as a privy and a hand pump on a shallow well, was estimated to range from less than \$10 for each member of the population in New England and on the Pacific Coast to more than \$20 in parts of the south, where the needs were greater and where the degree of urbanization was less.

A 1948 estimate of the cost of constructing a house sewer, septic tank, distribution box, and 100 to 200 feet of absorption trench for a rural sewage disposal system gave figures which ranged from \$110 in the southern United States to \$525 in the north. The level of construction costs today is somewhat higher. Estimates for cleaning such a system range from \$14 for the simplest of operations to \$300 for operations

involving, for example, taking up and replacing the tile distribution system.

Fifteen years ago, the sanitary pit privy cost roughly from \$20 to \$40 each in prewar dollars, the equivalent of from 50 to 100 man-hours. The greater part of the cost was for materials.

At present, a shallow well with a hand pump costs \$75 or more to install. A privy usually costs a similar amount. Three-fourths of the cost is for labor. The cost of a pump alone today ranges from \$4 for a simple manual pump to more than \$500 for a heavy duty power pump. Construction cost index numbers are roughly twice as high today as in 1938.

Costs of vector control have been calculated for specific projects. Malaria control in our southern States uses $2\frac{1}{2}$ man-hours and more than a pound of insecticide per dwelling per season. Ordinarily, the cost of residual spraying works out to less than \$1 per capita in these States, with labor charges the major factor. Typhus control in urban or village areas uses two-thirds of a man-hour and about $2\frac{1}{2}$ pounds of DDT dust per dwelling. Because of the appearance of resistant strains of insects, health departments cannot rely completely on chemical controls. Rat and fly control are directly associated with refuse disposal, but sanitary disposal of refuse in rural areas is laggard.

The economical approach to hookworm disease appears to require concentration on *afflicted families*, rather than a *mass approach*. At the same time, since a high iron and protein diet supports resistance to hookworm disease, mass economic improvement appears to be a means as well as an end in the process of hookworm control (13).

Costs of accident prevention, an important phase of sanitation, are not calculable on the basis of common experience, at present.

Administrative Considerations

Education also must be counted in the cost of sanitation. The economies of rural sanitation cannot be separated from the desires, needs, and interests of the people affected. Time and effort invested in helping the rural community to understand the need, purpose, and use of environmental health services also contribute

to the installation and maintenance of the necessary facilities. Too many installations go out of operation for lack of maintenance and repairs. Similarly, an installation may be wasted unless there is a parallel investment in developing local understanding and participation in an enduring sanitation program. Education is a major factor in the conquest of many rural hazards, both biological and physical.

In theory, a logical, orderly, and economical development of rural sanitation would begin with individual surveys to determine the environmental health needs of each rural home. These needs would be weighed against capacity to finance construction and installation.

In practice, the task of determining needs is handled more often by equipment and supply salesmen and the consumer than by health departments.

About the best that can be done by responsible health authorities or community leaders in this situation is to try to bring about a mutual understanding among the many parties interested in sanitary installations and services on both the buying and selling ends and to help them secure the required financial assistance. More and more, the businessmen themselves may develop systematic packaging and marketing of complete sanitary units for the rural household to improve random marketing of pumps, screens, concrete tanks, pipe, sinks, and tubs. The technical advice of health officials would contribute materially to this development.

The rural credit program as a whole has given less emphasis to sanitation than meets the need. Although the bulk of farm credit is provided by private lending institutions, several Federal agencies provide guaranties and other facilities for obtaining credit at moderate interest rates.

Credit for farm development, including sanitation, has been supported by the Federal Government since 1916. Several thousand units of low-rent public housing in rural areas have been built under credit supports provided by the United States Public Housing Administration. Loans and grants to improve private rural housing were authorized to the extent of \$19 million for administration in 1952 by the United States Department of Agriculture through the Farmers Home Administra-

tion. The funds were all committed within a few months. The Farmers Home Administration also issues loans to assist farm tenants to become farm owners, and it assists owners to develop farm property.

While these loans are not necessarily profitable, similar credit operations of the Department, through the Farm Credit Administration and the Rural Electrification Administration, have been self-supporting. Loans have always been available from REA for financing rural plumbing. And home construction loans by the Farmers Home Administration are issued under sanitary standards consistent with those recommended by public health agencies. If rural credit programs are assisted to a greater extent by the advice and resources of health authorities, it may be expected that rural sanitation and welfare will advance the more rapidly.

The experience of the Rural Electrification Administration suggests a time schedule that might be applied to rural sanitation. Electric power from a central station is provided on 90 percent of the farms in the United States. In 1935, only 10.9 percent of farms were so electrified, only 0.9 percent in the least developed States, and only 53.9 percent in the best. The percentage of electrified farms in each State today ranges from as high as 98.9 to no lower than 65. Judging by the pace of rural electrification, it should be possible to satisfy the bulk of environmental health needs in rural areas within a generation.

NOTE. Unless otherwise indicated, the economic statistical data are taken from tables published by the United States Department of Commerce, the United States Department of Agriculture, and the Federal Reserve Board. An extensive list of references on the general subject of rural health is available from the United States Department of Agriculture Library (Rural Health; Annotated list of selected references; Library list No. 60, 1953).

Services of Preventive Medicine

To an Observed Population

Public Health Monograph No. 16 contains data on personal preventive medical and related services for each member of a group of families canvassed monthly over a 5-year period, 1938-43, in the Eastern Health District of Baltimore. The services recorded were dental care, eye refractions, immunizations, complete physical examinations, and checkups following surgery or medical treatment or exposure to communicable disease.

Maximum dental cases and visits occur under 20 years of age but rates were high from 5 to 30 years of age. Rates for fillings, prophylaxis, and crowns and bridges, are highest under 20 years of age, and decline thereafter. Extractions and X-ray have their highest rates in middle life; plates, at 40 to 50 years of age. Except for the young and old ages, females have considerably more dental service at each age. Persons with higher incomes received more dental service than those with lower family incomes. Similarly, persons in professional-business-clerical occupations received more dental care than those in manual occupations. The proportion of dental care received in public clinics decreased rather regularly and considerably during the 5-year period.

Of all eye refractions, 47 percent were done by optometrists or opticians, 33 percent in clinics, and 20 percent by private physicians, of whom about two-thirds were eye physicians. The age curve for eye refractions shows two peaks, 10-14 and 45-54 years. At every age except the oldest, the refraction rates were definitely higher for females than for males. For females, refraction rates are highest in Sep-

Public Health

MONOGRAPH

No. 16

The accompanying summary covers the principal findings presented in Public Health Monograph No. 16, published concurrently with this issue of Public Health Reports. The authors are with the Division of Public Health Methods, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Collins, Selwyn D., and Phillips, F. Ruth: Dental, eye, and preventive medical services. Public Health Monograph No. 16 (Public Health Service Publication No. 290). 28 pages. Illustrations. U. S. Government Printing Office, Washington, 1953. Price 20 cents.

tember and February, but rates for males show little regular seasonal variation.

Well-baby and child care, complete examinations, and checkups are definitely more frequent in clinics than in private practice, 68 to 84 percent being done in public clinics. However, less than half of prenatal care and postpartum examinations were done by clinics. In the frequency of these examinations, all except those relating to pregnancy and the puerperium were highest under 20 years of age, and well-baby and child care was largely under 5 years with a peak at 1 year of age. Age-adjusted rates for complete examinations increased with income but the opposite was true of checkups. Age-specific rates for well-baby and child care, particularly under 5 years of age, decreased rapidly as income increased.

Smallpox, diphtheria, and whooping cough annual immunizations amounted to 106, 97, and 26, respectively, per 1,000 children under 10 years of age. During the 5 years of the study more than half of the first 2 immunizations were done in public clinics, but 99 percent of the whooping cough immunizations were done by private physicians. Diphtheria and whooping cough immunizations were done at the earliest ages, the peak rates occurring under 1 year of age followed by a rapid decline. Smallpox vaccinations occurred at roughly the same frequency in each single year of age under 5 years, with a moderate drop thereafter. Smallpox and diphtheria immunizations per 1,000 children under 5 years of age decreased regularly as the family income increased but the opposite was true for whooping cough.

1,300 Projects Completed

To date 1,300 projects under the Hospital-Survey and Construction Program have been completed and put into operation. More than 700 projects are under construction, with 120 in preconstruction stages. Cost of all construction now totals more than \$1,700,000,000. Communities and States have supplied more than \$1 billion of this amount. The Federal Government's share is nearly \$600 million.

Final 1952 Report On Tuberculosis Morbidity United States and Territories

A total of 109,837 tuberculosis cases was newly reported in the continental United States during 1952, according to final reports received from State health departments. This figure represents a decline of 7 percent from the total reported in 1951. Part of this decline is accounted for by changes in the types of cases reported.

This is the first year in which new tuberculosis cases reported have been classified as group A (active and probably active) and group B (arrested and other reportable cases), as recommended by the State directors of tuberculosis control at their 1951 meeting in Cincinnati (1). Although the types of cases reported as group B vary widely from State to State, those reported as group A are fairly uniform. Group A tuberculosis cases newly reported to State health departments during 1952 totaled 85,607—an annual rate of 55.0 per 100,000 population.

The number of active and probably active cases reported in 1952 for each of 6 States was estimated because of the incompleteness of classification, which had a bearing on the count of active cases. Some of these States, however, have since adopted new morbidity reporting procedures so that all States probably will provide information on the number of newly reported active and probably active tuberculosis cases during 1953.

The accompanying table gives the data from the States and Territories. The newly reported active and probably active tuberculosis cases per 100,000 population varied among the States from a high of 164.0 for Arizona to a low of 16.4 for Nebraska. The rates for Alaska and

This report was prepared by the Division of Chronic Disease and Tuberculosis, Public Health Service.

Puerto Rico were substantially higher than the rate for Arizona. No doubt part of the difference in rates reflects the relative effectiveness of case finding and reporting in each State. On the other hand, it seems probable that large

differences in the rates generally indicate actual differences in the incidence of the disease.

Membrane Filter Procedure Applied in the Field

By EDMUND J. LAUBUSCH, M.S., EDWIN E.
GELDREICH, M.S., and HAROLD L. JETER, M.A.

IN THE PLANNING of public health procedures appropriate for field use or in the event of a natural or wartime disaster, there is a recognized need for quick detection of bacterial pollution of water supplies. For this purpose, application of membrane filter techniques has been proposed, primarily because the 4 to 5 days required to perform coliform enumerations can be reduced to 18 to 20 hours by use of the membrane filter, without apparent loss of validity of results.

Application of the membrane filter in an emergency implies that the tests be completed under field conditions, with minimum availability of standardized laboratory equipment and supplies. It is recognized, also, that in certain situations there may be need for culture incubation by other methods than conventional laboratory incubation. Previous descriptions (1, 2) of EHC Endo medium have specified preparation of the medium on the day of use, thereby necessitating probable preparation under field conditions. In addition, the fragility of glass petri dishes renders them of questionable value in such operations.

The studies which are reported here dealt with (a) a specially designed garment to incubate inoculated membrane filters, utilizing body warmth as a source of heat; (b) the applicability of more durable containers to field-culture methods; and (c) the feasibility of using stored, fully prepared Endo medium to avoid the necessity of mixing the medium in the field.

Mr. Laubusch is a sanitary engineer with the Division of Sanitation, Public Health Service, Washington, D. C.; Mr. Geldreich and Mr. Jeter are bacteriologists with the Environmental Health Center, Cincinnati, Ohio.

Garment for incubation of inoculated filters by body heat of wearer.

Sample Filtration

Equipment suitable for membrane filtration has been adequately described (1-4). All the filtrations in this investigation were made in the laboratory, in order to compare the "field type" of test with the laboratory test as a control procedure. An electric vacuum pump was the only piece of equipment used that might not be available in a disaster area. Samples of water were collected in bulk and were filtered within 2 to 3 hours from the time of collection.

Use of the standard metal or glass-holding apparatus is feasible for field work. The differential pressure across the membrane can be obtained by using a hand-operated bicycle pump with the leathers reversed, a rubber bulb aspirator, or an evacuated container. Field sterilization of the apparatus can be accomplished by immersion for 5 minutes in boiling water, by flaming alcohol, or by the incomplete combustion of methyl alcohol (1, 2, 5). Re-sterilization of the filter holder between filtrations of successive samples is not usually re-

quired. Rinsing down the funnel walls with a small amount of sterile water two or three times, after sample filtration but before removal of the membrane, reduces the residual micro-organisms to insignificant levels.

Culture Containers

A satisfactory container should: (a) be non-breakable, of chemically inert material which can be easily cleaned; (b) be suitable for sterilization either by heat or by chemical procedures; (c) have air- and water-tight seal, to prevent leakage of medium, contamination, or loss of humidity; (d) be convenient to use, inexpensive, and readily available.

Probably no single type of container fully meets all of these requirements. Two types of containers have been examined extensively with regard to the above criteria. One was an ordinary 2-oz. ointment tin, 50-60 mm. in diameter, available from most laboratory equipment distributors, large drug stores, or drug supply companies. The other was a disposable plastic petri dish, 50 mm. in diameter. Tests using these containers were run in parallel with the 60-mm. glass petri dishes routinely used in this laboratory for membrane filter studies.

Culture Media

All membranes were incubated for 2 hours on M-enrichment medium (Difco) followed by transfer to EHC Endo medium for final incubation of 16 to 18 hours. The EHC Endo medium used in the medium storage experiments was kept in screw-capped tubes until time for use.

Sterilization Procedures

In these investigations, a laboratory autoclave was used to sterilize all materials. For field use, a pressure cooker (such as is used for home-canning purposes) could be substituted.

Equipment, such as funnels, metal containers, and graduates, was sterilized for 15 minutes at 121° C. (15 lbs.). Whenever it was necessary to dry this equipment rapidly, the escape valve of the autoclave was opened to reduce the steam pressure.

(The plastic petri dishes could be sterilized

by soaking for 2 hours or longer in 70-percent ethyl alcohol. The alcohol must be allowed to drain from the dishes before using them.)

The membrane filters were separated from the kraft paper dividers (leaving the white blotting paper inserts in place), wrapped loosely in kraft paper (about 10 to each package), and sterilized in the autoclave for 10 minutes at 115° C. (10 lbs.). At the end of the sterilization period, the escape valve was opened to reduce the pressure in the autoclave to atmospheric pressure. (This was essential to protect the membranes from excessive moisture.)

The enrichment medium and EHC Endo base were autoclaved 15 minutes at 121° C. The 20-percent lactose solution was autoclaved 10 minutes at 115° C.

Field Incubation

The incubation assembly (see photograph) consisted of a sleeveless, vestlike garment, adaptable to a torso of almost any size and equipped with adjustable elastic strappings to hold the garment in place and to permit maximum dexterity of the operator. The vest, worn in direct body contact for maximum heat transfer, held 21 incubation containers in pouches located on the front side. Incubation containers were inserted vertically into these pouches so that the bottom (thus, the nutrient pad and membrane) was closest to the body and was separated from the skin by a nylon marquisette fabric which formed the inner lining of the garment. The front side of the pouches was lined with nylon-faced, rubberized cloth to minimize heat losses. A heavy-grade cotton oxford cloth was used as an overlay veneer and extended around the back of the torso, where it was fastened.

Experimental tests consisted of body incubation of inoculated membranes, contained in metal and plastic containers, for the established periods. Parallel tests were made with membranes cultured in glass petri dishes and incubated in a laboratory high-humidity incubator at 35° C.

Results

In table 1, quantitative coliform recovery in the metal and plastic dishes is compared

Membrane Filter Procedure Applied in the Field

By EDMUND J. LAUBUSCH, M.S., EDWIN E. GELDREICH, M.S., and HAROLD L. JETER, M.A.

IN THE PLANNING of public health procedures appropriate for field use or in the event of a natural or wartime disaster, there is a recognized need for quick detection of bacterial pollution of water supplies. For this purpose, application of membrane filter techniques has been proposed, primarily because the 4 to 5 days required to perform coliform enumerations can be reduced to 18 to 20 hours by use of the membrane filter, without apparent loss of validity of results.

Application of the membrane filter in an emergency implies that the tests be completed under field conditions, with minimum availability of standardized laboratory equipment and supplies. It is recognized, also, that in certain situations there may be need for culture incubation by other methods than conventional laboratory incubation. Previous descriptions (1, 2) of EHC Endo medium have specified preparation of the medium on the day of use, thereby necessitating probable preparation under field conditions. In addition, the fragility of glass petri dishes renders them of questionable value in such operations.

The studies which are reported here dealt with (a) a specially designed garment to incubate inoculated membrane filters, utilizing body warmth as a source of heat; (b) the applicability of more durable containers to field-culture methods; and (c) the feasibility of using stored, fully prepared Endo medium to avoid the necessity of mixing the medium in the field.

Sample Filtration

Equipment suitable for membrane filtration has been adequately described (1-4). All the filtrations in this investigation were made in the laboratory, in order to compare the "field type" of test with the laboratory test as a control procedure. An electric vacuum pump was the only piece of equipment used that might not be available in a disaster area. Samples of water were collected in bulk and were filtered within 2 to 3 hours from the time of collection.

Use of the standard metal or glass-holding apparatus is feasible for field work. The differential pressure across the membrane can be obtained by using a hand-operated bicycle pump with the leathers reversed, a rubber bulb aspirator, or an evacuated container. Field sterilization of the apparatus can be accomplished by immersion for 5 minutes in boiling water, by flaming alcohol, or by the incomplete combustion of methyl alcohol (1, 2, 5). Re-sterilization of the filter holder between filtrations of successive samples is not usually re-

quired. Rinsing down the funnel walls with a small amount of sterile water two or three times, after sample filtration but before removal of the membrane, reduces the residual micro-organisms to insignificant levels.

Culture Containers

A satisfactory container should: (a) be non-breakable, of chemically inert material which can be easily cleaned; (b) be suitable for sterilization either by heat or by chemical procedures; (c) have air- and water-tight seal, to prevent leakage of medium, contamination, or loss of humidity; (d) be convenient to use, inexpensive, and readily available.

Probably no single type of container fully meets all of these requirements. Two types of containers have been examined extensively with regard to the above criteria. One was an ordinary 2-oz. ointment tin, 50–60 mm. in diameter, available from most laboratory equipment distributors, large drug stores, or drug supply companies. The other was a disposable plastic petri dish, 50 mm. in diameter. Tests using these containers were run in parallel with the 60-mm. glass petri dishes routinely used in this laboratory for membrane filter studies.

Culture Media

All membranes were incubated for 2 hours on M-enrichment medium (Difco) followed by transfer to EHC Endo medium for final incubation of 16 to 18 hours. The EHC Endo medium used in the medium storage experiments was kept in screw-capped tubes until time for use.

Sterilization Procedures

In these investigations, a laboratory autoclave was used to sterilize all materials. For field use, a pressure cooker (such as is used for home-canning purposes) could be substituted.

Equipment, such as funnels, metal containers, and graduates, was sterilized for 15 minutes at 121° C. (15 lbs.). Whenever it was necessary to dry this equipment rapidly, the escape valve of the autoclave was opened to reduce the steam pressure.

(The plastic petri dishes could be sterilized

by soaking for 2 hours or longer in 70-percent ethyl alcohol. The alcohol must be allowed to drain from the dishes before using them.)

The membrane filters were separated from the kraft paper dividers (leaving the white blotting paper inserts in place), wrapped loosely in kraft paper (about 10 to each package), and sterilized in the autoclave for 10 minutes at 115° C. (10 lbs.). At the end of the sterilization period, the escape valve was opened to reduce the pressure in the autoclave to atmospheric pressure. (This was essential to protect the membranes from excessive moisture.)

The enrichment medium and EHC Endo base were autoclaved 15 minutes at 121° C. The 20-percent lactose solution was autoclaved 10 minutes at 115° C.

Field Incubation

The incubation assembly (see photograph) consisted of a sleeveless, vestlike garment, adaptable to a torso of almost any size and equipped with adjustable elastic strappings to hold the garment in place and to permit maximum dexterity of the operator. The vest, worn in direct body contact for maximum heat transfer, held 21 incubation containers in pouches located on the front side. Incubation containers were inserted vertically into these pouches so that the bottom (thus, the nutrient pad and membrane) was closest to the body and was separated from the skin by a nylon marquisette fabric which formed the inner lining of the garment. The front side of the pouches was lined with nylon-faced, rubberized cloth to minimize heat losses. A heavy-grade cotton oxford cloth was used as an overlay veneer and extended around the back of the torso, where it was fastened.

Experimental tests consisted of body incubation of inoculated membranes, contained in metal and plastic containers, for the established periods. Parallel tests were made with membranes cultured in glass petri dishes and incubated in a laboratory high-humidity incubator at 35° C.

Results

In table 1, quantitative coliform recovery in the metal and plastic dishes is compared

with recovery in the control test, in which glass dishes were used. Counts are average values of duplicate membranes. All water samples were from farm wells.

Average coliform counts of four replicate samples from a group of rural well waters incubated in the conventional, constant-temperature, high-humidity incubator, and a parallel series incubated at body temperature in the incubator vest, are shown in table 2. Both types of containers, the ointment tin and the plastic petri dish, were used in this evaluation.

Coliform recoveries on stored EHC Endo medium, as compared with the results from freshly prepared EHC Endo medium, are shown in table 3.

These values were based on four replicate filtrations for each of the two media.

Discussion

Comparison of coliform recovery results from the tin and from the plastic containers (table 1) with the recoveries from standard glass petri dishes indicated that any of these containers could be used interchangeably. Lab-

oratory observations demonstrated no consistent variation in either colony size or quality of the characteristic sheen of coliform colonies.

Both the plastic dish and the metal container satisfied most of the criteria outlined for optimum field performance. It was shown that these containers could be incubated in any position without interference from spreading growth caused by condensed moisture falling on the membrane. There appeared to be sufficient adhesive power in a properly saturated nutrient pad to keep the membrane in a fixed position on the bottom of the container. The containers were sufficiently tight to prevent evaporation of the nutrient and to preserve a sufficiently humid atmosphere. (However, several containers were not leakproof, so that medium did seep out. This resulted in staining the incubator vest and occasionally the clothing worn adjacent to the vest.)

Other discomforts to the wearer were associated with continuous wearing of the vest, such as heat buildup and difficulties in sleeping. Under nonemergency conditions, some other means of supplying suitable temperatures, for example, a portable incubator or thermos jar,

may better serve the purpose of incubation in field examinations of water supplies.

Steam or hot-air sterilization of the metal culture containers resulted in development of scale and rust after repeated use. Both types of culture containers were considered to be disposable, and could be taken into the field in a sterile condition, used once, and discarded. The low cost of these containers made the practice economically feasible.

According to the data in table 2, it appeared that when the body served as the source of heat, coliform recoveries were equal to those obtained from conventional incubation. Colonies incubated by body heat were noticeably smaller, necessitating occasional extension of incubation time to insure complete development and optimum differentiation of coliform colonies. The smaller size often was advantageous, because it helped to minimize interference with coliform differentiation due to overcrowding and confluence of colonies.

Frequent random temperature observations in the pouches of the incubation vest, made over a 6-week period in which the vest was used, indicated maintenance of a relatively constant and uniform temperature range. The limits were 33.5° C. and 35.5° C.

From the data in table 3, it appeared that

limited-duration storage of the EHC Endo medium had no discernible effect on quantitative coliform recovery. Similarly, colony size and sheen characteristics appeared not to be adversely affected with storage up to 3 or 4 weeks. Thus, fully prepared Endo medium, previously mixed in the laboratory, can be taken out into the field for medium-transfer purposes.

These results suggest application of field incubation procedures to small-scale surveys in remote areas where accurate results must be obtained quickly by starting or completing incubation at the sampling site. The body incubation modification is particularly applicable

Table 3. Average coliform recoveries on stored and freshly prepared medium

32-----	1. 09	1. 00

to civil defense activities and disaster relief, where laboratory facilities may not be conveniently available.

Conclusions

1. Both tin and plastic containers possess the merits of simplicity, mechanical durability, and membrane filter adaptability.

2. Equally satisfactory results are obtainable by use of the metal or the plastic container as a culture dish for membrane filters.

3. The incubator vest is an acceptable device for utilizing body heat for the incubation of membrane filters under field or emergency conditions.

4. The EHC-modified Endo medium may be stored for 3 or 4 weeks without destroying the usefulness of the medium.

Public Health Service Staff Announcements

Dr. Harold M. Janney has been appointed medical director of the Bureau of Prisons, Department of Justice. Since 1950 Dr. Janney has been medical director of the United States Penitentiary, Atlanta, Ga. He has had progressively responsible appointments in the Federal prison system since his initial Public Health Service assignment as medical staff officer at the Federal Reformatory, Chillicothe, Ohio, in 1936.

Dr. Joseph O. Dean, formerly associate chief of the Bureau of State Services, Public Health Service, on September 15 was named as an assistant to the medical director of the Bureau of Indian Affairs, Department of the Interior. Prior to his assignment as associate chief in 1949, he served as district director and regional medical director of Region VII, with headquarters in Kansas City, Mo.

Dr. Dean was appointed to the Regular Corps of the Public Health Service in 1929, and received his master of public health degree in 1937 from the Johns Hopkins School of Hygiene and Public Health. During his career, he served at quarantine stations in New York and New Orleans. From 1937 to 1941 he made studies of public health administration in rural areas and also of the activities of various county health departments. From 1941 to 1944 he was stationed in San Juan, Puerto Rico, as medical consultant.

During World War II, Dr. Dean was concerned with activities relating to emergency health and sanitation, serving first as assistant chief of the Division of States Relations and later as chief of the Office of Surplus Property. From October 1946 to October 1947, he was assistant chief of the Division of Commissioned Officers.

Demographic Characteristics of Latin America

Limited and brief though it is, this review emphasizes the magnitude of the disease problem in Latin America. It supports the thesis that the population is young, that mortality rates are high (especially in the early years of life), and that infectious and parasitic diseases are responsible for most of the morbidity and mortality drain on the population.

MOST OF THE TERRITORY of the Latin American Republics lies between the Tropic of Cancer and the Tropic of Capricorn. During the decade 1942-52, the Institute of Inter-American Affairs cooperated in the field of public health with 18 of the 20 countries in this region. Fourteen of these 18 countries are wholly within the Torrid Zone. Only one, Uruguay, is completely in the Temperate Zone. The remaining three lie partly in both zones. It is therefore to be expected that tropical or subtropical diseases would be found in almost all of these countries. In the areas of high altitude, which characterize the Andean regions in particular, the diseases are likely to

be those of a Temperate Zone, though the region lies completely in the Tropics.

The *Servicios*, therefore, were confronted with both temperate and tropical disease problems. The characteristics of the problems were not difficult to define, but their magnitude was less readily determined. The reasons for the latter stem, in considerable part, from the inadequacies of the morbidity and mortality data available. By using both direct and indirect evidence, however, it was possible to formulate a reasonably true picture of the disease problems.

Mortality Rates

Data on the number of deaths and the death rates in seven Latin American countries for 1942 and 1949 (table 1) indicate that considerable improvement in health conditions has taken place during this 7-year period. When these data are compared with comparable data for the United States (table 1), however, it is evident that these countries are in a position to benefit still more from intensive efforts to improve health services. For example, the crude death rate in Chile in 1949 was 2.2 per 1,000

This material on demographic characteristics and that following on specific diseases and nutrition are the sixth and seventh in a series of excerpts from the report on the Public Health Service's evaluation of a decade of cooperative health programs of the Institute of Inter-American Affairs. The background of the report and of these excerpts will be found in Public Health Reports for September 1953, beginning on page 829.

population lower than the rate in 1942; yet in both years the Chilean rate was about twice that for the United States.

By Age

More significant than general death rates are the rates by age and by cause of death. The data in table 2 show that people in the five Latin American countries shown are prone to

die young. The mortality rates for the first year of life and for the succeeding 4 years are uniformly high in comparison with the rates for the United States. These rates are known to be susceptible of substantial and rapid reduction by effective health services. The evidence, therefore, leads to the conclusion that uniformly effective health services have not yet been developed in most of these countries.

By Causes of Death

The value of mortality data for specific diseases, such as those shown in table 3, in defining the disease problems of Latin America is limited by two factors. First, the proportion of registered deaths in many Latin American countries listed as due to ill-defined or unknown cause is comparatively large. For example, in the countries included in the table, the percentages of registered deaths recorded as due to ill-defined or unknown cause were 23.6 for Colombia, 15.2 for Peru, 6.0 for Costa Rica, and 21.0 for El Salvador; the percentage for the United States was 1.2. Second, medical certification applies to only a part of the registered deaths. In Colombia, 41.7 percent of registered deaths in 1947 were medically certified. In the same year, the percentage in Costa Rica was 59.0; in El Salvador, 16.7; in Mexico, 51.0; in Chile, 71.8; and in Uruguay, 97.7.

Despite these limitations, there is fair agreement among the specific disease rates for the

several countries. The highest mortality rates among the infectious diseases are usually for diarrhea and enteritis, followed by those for tuberculosis, malaria, and whooping cough, but with bronchitis and influenza frequently occupying important positions. It may be that some of the tuberculosis deaths are reported as bronchitis deaths, which would serve to magnify the importance of the latter.

Striking Differences

When the specific disease rates of these four Latin American countries are compared with those of the United States, the most striking differences are (a) the higher incidence of deaths due to the infectious diseases, especially those usually associated with infancy and early life; and (b) the lower incidence of deaths from cancer, heart disease, and nephritis, which are characteristic of the later years of life. A similar picture is presented in table 2, in that the favored mortality position of the younger age groups in the United States largely dis-

Table 3. Number of deaths and death rates per 100,000 population in five countries, by selected cause (stillbirths excluded)

Cause	United States 1948		Colombia 1948		Peru 1948		Costa Rica 1949		El Salvador 1948

appears in the older age groups where the degenerative diseases begin to take their toll.

The young-age deaths that characterize the Latin American countries constitute a tremendous drain on the human resources of the region and are an economic handicap of first importance. The seriousness of the situation is mitigated only by the knowledge that these deaths are largely preventable.

As a result of the high mortality in Latin America, especially during infancy, life expectancy is well below that of Western Europe, Canada, and the United States. In Latin America it ranges from 35 years in Venezuela (1949) to 46 in Colombia (1947); in Canada and the United States, it is from 65 to 70 years.

Morbidity Rates

The damage inflicted upon a population by disease is measured more accurately by the number of illnesses produced than by the number of deaths that ensue. Typhoid fever, for example, results in death in about 10 percent of the cases, and this percentage is substantially lowered when appropriate treatment with chloromycetin is employed. Malaria, which ranks with tuberculosis as the world's most prevalent disease, produces death in a relatively small percentage of cases. A somewhat similar situation occurs with most of the infectious and parasitic diseases of man. It is clear, therefore, why the mortality record is quite inadequate to evaluate the burden occasioned by disease. The incapacitation and economic loss that result from illnesses are together the true measure of their importance to mankind.

It is well known that the reporting of illnesses in Latin America is incomplete. Even if a satisfactory reporting system could be devised, it could not operate in these countries since in none of them is there a sufficient number of physicians to attend all the sick. In many sections, notably the rural areas, there are no physicians at all. The most reliable statistics are to be found in the cities and towns where physicians are relatively numerous.

Some idea of the volume of illnesses in Latin America may be obtained from the data for Colombia shown in table 4. It can be estimated that there were at least 1,000,000 illnesses in this country in 1948, if the experience in the half of the population not represented by these data was similar to that shown. Taking into account the many illnesses unattended by a physician and the many that for one reason or another were not reported, the number was probably much greater. In the same year Colombia reported 154,392 deaths from all causes. The total picture of disease thus includes the morbidity as well as the mortality experience.

Table 4. Reported illnesses in Colombia, 1948

[209 of 815 municipalities reporting, representing about half of Colombia's population]

Illness	Number of cases	Rate per 100,000 population
Malaria.....	89,727	1,655
Influenza.....	75,756	1,398

Disease and Nutritional Barriers to Health

Clearly, ill health *reduces manpower and retards economic progress*. In these excerpts some of the specific disease problems of our southern neighbors are outlined, and some of the main lines of attack by the Servicios are traced. The "nutritional spectrum," heavily weighted on the side of malnourishment, is described, together with the efforts toward improvement.

EXAMINATION of mortality and morbidity data leads to the conclusion that malaria and tuberculosis were the outstanding disease problems in Latin America during the decade 1942-52. Such diseases as yaws, hookworm disease, Hansen's disease, schistosomiasis, and epidemic typhus, however, also constituted problems, and in some areas one or another of these rivaled malaria and tuberculosis for a top-ranking position.

In Haiti, for example, it is believed that yaws has attacked one-third of the population of 3,000,000 and that at any one time there are at least 50,000 active cases.

Hookworm disease was, and still is, a major problem in tropical and subtropical areas where climatic and soil conditions are favorable and where the disposal of human feces is improperly provided for. This disease represents a heavy burden on the productive capacity of the population.

There are more than 37,000 known cases of Hansen's disease in Brazil, 8,000 in Colombia, and about 8,000 in Mexico. Other countries have a few hundred to a few thousand cases each. Since there are no certain means of preventing or of curing this disease, it is still necessary to provide custodial care for thousands of infected individuals.

Schistosomiasis is limited to a few areas of Latin America, but the necessary intermediate host, a snail of the genus *Planorbis*, is widely

distributed in several of the countries. This disease represents a serious threat since as yet no wholly practical and effective means of control has been devised.

Epidemic typhus and murine, or endemic, typhus are prevalent in the Andean region particularly and may be found in other parts of Latin America. Fortunately, the means to control epidemics, and perhaps to prevent them as well, are available.

Other diseases found in Latin America include Chagas' disease, plague, bartonellosis, brucellosis, and onchocerciasis, as well as the more commonly known diseases, such as typhoid fever, the dysenteries, smallpox, diphtheria, measles, and whooping cough.

Though knowledge is far from complete in respect to the importance of specific diseases in infant mortality, it is generally accepted that a major portion of the infant deaths result from intestinal infections. The *Shigella* and *Salmonella* groups of bacteria and probably certain viruses which are as yet not clearly determined are the causal agents. Malnutrition, either alone or in conjunction with an infectious agent, is also assigned a significant role in infant deaths.

Chiefs of Field Party Analysis

A series of reports drafted by the chiefs of the United States field parties offered an op-

portunity to compare the conclusions reached by a study of official records with the impressions and opinions of competent resident observers.

In 1949, the chiefs of field party had been requested to furnish a list of the 10 diseases which were considered the most serious public health problems in the countries in which they were resident. Since the instructions did not specify the characteristics of a disease which permit it to be designated a public health problem nor provide criteria whereby importance might be measured, it was to be expected that the replies would lack uniformity and would include a wide range of disease entities.

A total of 35 different diseases were enumerated as major public health problems in the 13 lists returned. Of these only one disease, tuberculosis, appeared in all the lists. Syphilis and typhoid fever were each included in 12 lists, malaria in 11, and whooping cough in 10. No other disease approached such unanimity except measles, which was included in 8 lists.

Such intestinal diseases as diarrhea, enteritis, the dysenteries, typhoid fever, and paratyphoid fever considered as a group, as is justifiable on epidemiological grounds, were listed 25 times. Acute infectious diseases—whooping cough, measles, diphtheria, chickenpox, meningitis, and smallpox—were listed 31 times.

First priority was accorded tuberculosis on 7 lists and malaria on 3; the remaining 3 lists gave priority to whooping cough, yaws, and “diarrhea and enteritis under 2 years of age,” respectively.

The interesting feature of this analysis is not the diverse responses, but the agreement among the chiefs of party as to the diseases which deserve to rank as the first five. These were tuberculosis, syphilis, the enteric infections, malaria, and whooping cough, the very same infectious diseases commonly found to rank high in the morbidity and mortality records of Latin America. With the exception of tuberculosis, these diseases respond favorably to prophylactic and therapeutic measures commonly available, and none of them needs to remain a potent enemy to man. The various Latin American national health services have it within their power to reduce the prevalence of any or all of them to relatively small proportions.

Nutrition

Nutrition plays a determining role in the health of every individual, irrespective of race, age, sex, occupation, or place of residence. The well-nourished and the malnourished, including both the overnourished and the undernourished, form a complete nutritional spectrum of every population group. Studies made in Latin America indicate that the nutritional spectrum is heavily weighted on the side of malnourishment in large groups of the population, but until additional, extended studies have been made, no reliable estimate of its distribution is possible. From casual observation, it is assumed, however, that malnutrition is an important problem.

On the basis of spot surveys and laboratory studies, the National Institute of Nutrition of Colombia claims that poor nutrition affects a large portion of the population of that country. This was evidenced by altered height, weight, and body measurements of the people as well as by decreased work capacity and the presence of clinical findings. The diet of the Colombians was shown to be low in proteins, fats, vitamins, and essential minerals, and to be high in carbohydrates.

It is well known that hookworm disease, malaria, and tuberculosis are intimately related to malnutrition in many persons who suffer from these diseases, but whether or not the relationship is causal defies affirmation except in certain individual situations. The sufferer of malaria or hookworm disease may be malnourished because of the anemia that reduces his productive and earning capacity and therefore his ability to provide for his food needs. Or the malnourished person, as a result of diminished resistance, may fall an easy victim to such diseases. Whatever may be the relationship, it is clear that the well-being of the individual is compromised by malnutrition as well as by certain specific diseases.

By 1942, a number of the Latin American countries were already interested in nutrition. Uruguay created a Department of Nutrition and Dietetics in its Ministry of Health in 1934, and about the same time a National Commission for Nutrition was formed. Two years later Mexico established a Nutrition Re-

portunity to compare the conclusions reached by a study of official records with the impressions and opinions of competent resident observers.

In 1949, the chiefs of field party had been requested to furnish a list of the 10 diseases which were considered the most serious public health problems in the countries in which they were resident. It is well known that hookworm disease, malaria, and tuberculosis are intimately related to malnutrition in many persons who suffer from these diseases, but whether or not the relationship is causal defies affirmation except in certain individual situations. The sufferer of malaria or hookworm disease may be malnourished because of the anemia that reduces his productive and earning capacity and therefore his ability to provide for his food needs. Or the malnourished person, as a result of diminished resistance, may fall an easy victim to such diseases. Whatever may be the relationship, it is clear that the well-being of the individual is compromised by malnutrition as well as by certain specific diseases.

By 1942, a number of the Latin American countries were already interested in nutrition. Uruguay created a Department of Nutrition and Dietetics in its Ministry of Health in 1934, and about the same time a National Commission for Nutrition was formed. Two years later Mexico established a Nutrition Re-

tain records which would permit a fair evaluation of precisely what was accomplished. This was not done systematically.

Importance of Nutrition

Servicio directors appeared to be unanimous in their belief that malnutrition was widespread and of such intensity as to constitute a serious health hazard in many parts of Latin America, but relatively little was done to improve the situation. The *Servicios* invested only 2.9 percent of their funds in nutrition projects and developed programs in but 5 of the 18 countries. Much greater attention should be devoted to the problem of nutrition in the future than has been accorded it so far.

Infant Diarrheas

Another area which calls for greater concentration is the infant diarrheas. Advances have

been made in knowledge of their etiology and epidemiology but not enough to enable the health worker of Latin America to bring them speedily under control. It is believed that additional field studies should be undertaken and persisted in. The hope of reducing the infant mortality which results from the infant diarrheas rests in the first instance upon research.

Conclusion

The infectious diseases and malnutrition together make up the principal disease burden of the people of Latin America. These diseases are a principal factor in producing the short life span characteristic of the population. Moreover, ill health reduces manpower and retards economic progress. It is recognized, however, that these diseases are largely preventable. Intensified public health measures will assuredly conquer them.

From THE CHILD

Cerebral-Palsied Children

Believing that many cerebral-palsied children like other youngsters can be brought up in their own homes—New York City has developed four special units for educating them in the public schools. At the same time, the handicapped children receive the special medical and health services they need. These advantages are particularly important for the children's emotional growth and development. From the long-range view, the classes are helping the children attain partial independence and productivity. (See Cerebral-Palsied Children Attend Special Classes in Public Schools—Drs. Helen M. Wallace, Leona Baumgartner, and William Cooper in the August-September 1953 issue of *The Child*.)

A Manual for the Operation of Cerebral Palsy Units in New York City is available

upon request from the Bureau for Handicapped Children, New York City Department of Health, 125 Worth Street, New York 13, N. Y.

Rheumatic Fever Problems

Parents with children convalescing from rheumatic fever have been brought together to discuss common problems and fears. They meet with the staff of the pediatric cardiac clinic at the Grace-New Haven (Conn.) Community Hospital. (Jean Kiningham Igersheimer and Drs. Charles Henry Crothers and Robert B. Kugel describe this program in the August-September issue.)

The Child is issued 10 times a year by the Children's Bureau, U. S. Department of Health, Education, and Welfare. \$1.25 a year (\$1.50 foreign mailing), 15 cents a copy, from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C.

Principles of Public Health Program Planning And Their Application in Latin America

Dividends are higher from any well-conceived operation, whether by business or government. Especially in public health undertakings, where outcomes are not easily measurable, is advance planning essential. Here the evaluators describe certain basic principles and the facts and figures necessary for complete program planning, and strike a balance from the record of inter-American cooperative programs.

THE PLANNING that had gone into 10 years of operation of the bilateral health programs of the Institute of Inter-American Affairs was examined and appraised on the basis of the following general considerations:

1. Program planning is one of the most important functions of management, whether the enterprise be in the field of business, government, or philanthropy.

2. Experience has shown that the benefits or dividends from operations vary directly with the quality of planning. Poorly conceived plans giving a minimum of benefit usually call for the expenditure of just as much effort and funds in their execution as do good ones.

3. A business enterprise is established primarily to make money, and when dividends de-

cline or cease, search is immediately made to determine what is wrong. No such automatic criterion exists to test the efficiency of social organizations such as government and philanthropy; therefore, management of these organizations calls for a very highly developed sense of responsibility and critical self-evaluation.

4. By definition, a program is a prearranged plan. Also by definition, a plan is an arrangement of means or steps for the attainment of some objective. Thus, if the objective is not clearly defined, the arrangement of appropriate means or steps to achieve it will be difficult, and the program will lack precision and completeness.

Institute Program Objectives

The program of the Institute of Inter-American Affairs had more precise objectives during its earlier years than in more recent ones. At the time of its establishment, the objectives were: (a) to improve health conditions in strategic areas, particularly with relation to the requirements of the Armed Forces of the United States and those of its American allies; (b) to carry out the obligations of the United States Government assumed by it under the resolution

This is the eighth in a series of excerpts from the Public Health Service's evaluation of a decade of operation of the Institute of Inter-American Affairs cooperative health programs. Background information on the evaluation survey and on the origin and structure of these programs can be found in the September 1953 issue of Public Health Reports, beginning on page 829.

regarding the health and sanitation problems of the Americas which had been adopted by the Third Meeting of Ministers of Foreign Affairs in Rio de Janeiro; (c) to make possible increased production of critical materials in areas where bad health conditions existed; and (d) to demonstrate by deeds as well as words the tangible benefits of democracy and to win active support of the civilian population.

The first three of these objectives were intimately related to the war effort, and the success in achievement could be measured objectively by the health records of the Armed Forces personnel stationed in the Latin American Republics and by the rate of production of critical materials. However, even though the primary aims were to meet an emergency need, there was a constant interest in long-range projects looking toward improvement of conditions in the hemisphere. Nonetheless, the program in the early years must be viewed as a part of the war effort and evaluated on that basis. A highly creditable level of achievement was attained during this period.

After the Second World War these objectives were replaced by others. In the Institute of Inter-American Affairs Act of 1947 (Public Law 369, 80th Cong.), which authorized the continuance of the Institute, it was stated that the purposes of the Institute should be "to further the general welfare of, and to strengthen friendship and understanding among, the peoples of the American Republics through collaboration with other governments and governmental agencies of the American Republics in planning, initiating, assisting, financing, administering and executing technical programs and projects, especially in the fields of public health, sanitation, agriculture and education."

In line with this directive the Institute declared that the broad, basic objective of its postwar program would be to raise the level of living of the people in the several American Republics, and it viewed this objective as within the framework of a larger one—peace and prosperity in the Western Hemisphere.

Thus, postwar objectives were general, and evaluation of success in attaining them was therefore more difficult. The task was further complicated by the fact that many forces were at work, striving to achieve the very same ob-

jectives. Since the survey was concerned with only one part of the Institute program—health and sanitation—the following criteria were established for measuring success: (a) the extent to which the indigenous health organizations were being developed and stabilized; (b) the rate at which programs and methods were being incorporated into the permanent public health structure; and (c) the extent to which health habits and practices of the people were being influenced.

Responsibility for Planning

The program in each country had to be directed toward the achievement of the broad objectives set forth in the basic agreements between the United States Government and the government of the host country. The responsibility for preparing a detailed plan of operation was shared by the minister of the unit of the host government in which the *Servicio* was established and the chief of the United States field party, who was usually also the director of the *Servicio*.

Program planning ranged from excellent to mediocre. There appeared to be a direct correlation between excellence of planning and the number of years a *Servicio* director had been in a given assignment. In several countries it was observed that the program had changed with each new chief of field party; therefore, the value that might be expected from prolonged intensive efforts was dissipated. Often planning was lost sight of in the pressure of discharging operational responsibilities.

In one country the program during the initial period resulted from dictation rather than joint planning. Instead of the appropriate type of program being determined on the basis of a study of the country's needs, it was determined ex cathedra by the minister and other high government officials. Ten new hospitals were built and 17 existing ones received substantial additions to their facilities. At the time of the field survey in late 1951, 3 of these new hospitals were still not in use. This was an example of poor planning, or more accurately, of no planning.

Foundation of Good Planning

A knowledge of certain basic facts concerning a country and its people is considered nec-

essary for sound program planning. Characteristics of the population, vital statistics, health institutions, health personnel, governmental structure, voluntary health agencies, social institutions and customs, economic status, and geography and climate are among the areas in which data should be obtained.

An increasingly active interest in program planning was found during the field survey in Latin America. Where the basic facts were incomplete and inadequate, steps were being taken to supplement them. It is recognized, of course, that the collection of basic data is a long and laborious task and that certain of the data will have to be kept current. Rarely will the director of the *Servicio* be able to accomplish the task by himself. The talents of all field party members and of many members of the national health service will have to be enlisted. A continuing responsibility for collecting and assembling basic data might well reside in a special committee appointed by the director of the *Servicio*.

Population Characteristics

The geographic distribution of the people is likely to have a direct bearing on the type of disease burden and the ease with which the people can be reached in a program for health betterment. If the population is predominantly rural, the problem of establishing contact between the people and the health service will tax the administrator's ingenuity, and this problem will be even greater if the rural population lives on scattered farms rather than in villages.

The age level of the population will indicate whether the program should be directed primarily toward the health hazards of infancy, youth, and early adult life or toward the diseases that characterize old age.

The principal occupations should be known since certain occupations have intrinsic health hazards. The lumberjack in the endemic areas of jungle yellow fever, for example, is in special danger of contracting the disease. Among certain types of miners, silicosis may be a hazard. The factory worker from rural areas appears to be especially susceptible to tuberculosis.

Racial composition of the population should

be determined since susceptibility and resistance to certain diseases are known to be in some way related to race.

Knowledge concerning literacy will have value in determining the most effective means of communication. The techniques used in health education, for example, will have to be adjusted accordingly.

Vital Statistics

An accurate census is essential in every field of social endeavor. It not only provides the information required to establish the characteristics of the population, but it permits calculation of rates and establishment of baselines which are necessary in measuring the effectiveness of health programs.

The number of births, deaths, marriages, and divorces by age and sex where appropriate and by political subdivision should be known. An effort must be made to determine the nature of the mechanism established for the collection of vital statistics and the precision with which it functions; otherwise, it will be impossible to judge the reliability of the statistics or to determine how they may be improved.

The causes of death and, if obtainable, the causes of illness, will help identify the principal diseases of a population. Frequently, the incidence of a disease in an area, or in an entire country, is unknown, and just as frequently no mechanism for ascertaining the facts exists. In such circumstances, a sampling survey may have to be undertaken. The prevalence of hookworm infestation, for example, was not appreciated in many Latin American countries 30 years ago. Surveys revealed that hookworm infestation affected up to 100 percent of the population and that actual disease occurred in from 10 percent to 50 percent or more.

Information as to the average family income should serve as an ever-present warning to avoid activities that call for expenditures by householders beyond their financial competence.

Health Institutions

The majority of health institutions are concerned with the prevention, diagnosis, and treatment of disease. They include the health departments with their health centers, specialized clinics, and other preventive services; the

laboratories for the control of water, milk, and other food products, and the diagnosis of morbid conditions; and hospitals of all types.

Another smaller group of institutions whose importance cannot be overestimated is the research group. These institutions determine in large measure the rapidity with which advances may be achieved in medical care, both preventive and curative. Often, of course, the institutions primarily concerned with the application of medical knowledge, such as hospitals, diagnostic laboratories, and health departments, also engage in research. Their investigations are as likely to be focused on administrative practices and organization as on medical knowledge per se.

A complete list of these several institutions is necessary to determine whether or not they are readily accessible to the population and to what extent they are capable of meeting the needs of the country.

Health Personnel

The number and distribution of medical and health personnel serving a population and the nature and capacity of institutions for training such personnel should be determined as accurately as possible. The number of physicians, engineers, dentists, dental hygienists, hospital administrators, nurses, nurse's aides, social workers, sanitarians, dietitians, and other specialized workers will indicate where expansion of training institutions is most needed. The extent to which such personnel is concentrated in urban areas, especially when the rural population carries the principal disease burden, must also be known. Some estimate as to the quality as well as the quantity of workers in the health and medical fields is highly desirable, though obviously more difficult to determine.

Governmental Structure

The organization and the functions of each part of the host government having a responsibility in the health field should be recorded.

Though the ministry of health in Latin American countries usually carries the major obligation for health services, the ministry of social welfare and the ministry of social security,

where these exist, frequently administer a part, if not all, of the hospitals and custodial institutions of a country. The ministry of education frequently has the obligation to maintain school health services and to this extent also shares in the administration of the nation's health services. This ministry's major responsibility in the health field, however, usually concerns the preparation of medical and health personnel. The ministry of public works is likewise tied in closely with the health field in view of its role in the construction, and often design, of hospitals, health centers, water supplies, and sewage treatment plants.

Voluntary Agencies

A careful analysis of the programs conducted by voluntary health agencies should be made so that due weight may be given them in planning the national health programs. The Red Cross, for example, frequently operates schools of nursing and health centers. In a number of countries a large part of the campaigns against tuberculosis and the venereal diseases is carried on by voluntary organizations.

Social Institutions and Customs

Social institutions, customs, and cultural traits are less easily identified and understood than the infectious diseases, for example, but they are equally important, if not more so, in planning health programs. The health planner needs to be familiar with the current beliefs of folk medicine and the attitudes of people toward modern scientific medicine. He must have an understanding of the habits of the people, the motivations of individuals, and their goals in life. Land tenure laws, social legislation, and housing are also important subjects in this field.

Economics

The economic potentialities of a country, as well as its present status, must be understood as a basis for realistic planning and as a means of protection against undertakings which are beyond the national resources. The level of productivity, the nature of the labor market, the trend towards industrialization, the national income, and the tax system are additional matters requiring investigation.

The fields of health, education, agriculture, and industry are interrelated and interdependent. If the level of living of a people is to be raised, no one of them may be ignored. The planner in the health field must therefore understand the problems of education, agriculture, and industry and, whenever possible, should seek ways and means whereby the health program will aid and reinforce programs in these fields and should attempt to utilize related programs to aid the health programs.

Geography and Climate

The geographic and climatic characteristics of a country have a direct relationship to many of its health problems. Not only physical factors, such as altitude, latitude, soil, insolation, temperature range, humidity, and rainfall, but many biological factors as well, are involved. The fauna and flora also determine in no small measure the health hazards of an area.

Formulation of a Program

The next step in program planning is to determine from a study of such basic data what the outstanding problems of the country are and which ones are susceptible of solution. It is at this stage of planning that the experience and judgment of the minister and the chief of field party are of crucial importance. They and their advisers must assign priority values to the several problems calling for solution. Program formulation may then proceed.

Depending upon circumstances, the program objective may be attained by a single project, such as the installation of a water supply system, or by a series of projects, such as those aimed at the control of tuberculosis. In the latter case, one project of the series might be an epidemiological study of tuberculosis to determine its incidence rate, the principal avenues of dissemination, or the role that BCG vaccination might be expected to play. Another project might be a case-finding campaign. Still another could be the establishment of a tuberculosis hospital.

Though projects will differ widely in their aims and provisions, they should resemble one

another in their formulation. The project agreement drawn up by the chief of field party and the minister should provide the following information: (a) the nature of the problem and objective of the project; (b) any previous projects which are similar; (c) a complete description of the project, including the location, the reasons for selection of the project, and the manner in which it is to be developed; (d) a clearly defined plan of administration; (e) the proposed time schedule; (f) arrangements for the transfer of the project to the national health service; (g) an estimate of the amount of money to be spent; and (h) the sources of funds.

The project agreement should be so complete and well documented that a new chief of field party or a new minister would have no difficulty in understanding the project or in discharging his responsibilities for its successful completion. The goal which the project aims to achieve should be precise and limited so that the accomplishment may be measured objectively.

Evaluation of Program Planning

In general, project agreements were found to be well prepared. The principal shortcomings were (a) the frequent omission of terminal dates, despite the fact that provision usually existed for an extension of the date if it were required; and (b) the absence of arrangements for the orderly transfer of responsibility for the project from the *Servicio* to the appropriate government agency.

Planning for Transfer

Chiefs of field party were sometimes reluctant to relinquish responsibility for completed projects for reasons that seemed unconvincing. For example, fear was expressed that a project when transferred to the host government would not be maintained at the same level of efficiency as under *Servicio* administration. If this fear were supported by facts showing, for example, a lack of funds or personnel to carry on the project, it could only mean faulty planning. Such prejudgments were regarded as neither persuasive nor trustworthy. The better procedure would have been to try out the new administrative auspices. If failure ensued,

then the reasons for failure could be identified and appropriate corrections applied.

In one instance, the director of the *Servicio* declared a certain health center, which had been in operation long enough to be considered an accepted method for providing preventive medical services, to be indispensable to him as a training center for *Servicio* personnel. In this particular country, the ministry of health had a section in its organization charged with responsibility for the training of personnel, which could have been used to meet the *Servicio's* needs.

An example of inadequate planning for the final transfer of a project to the constituted health authorities of the cooperating countries was found in one country. Although at the time of the survey, *Servicio* operations were in the hands of Latin Americans, difficulties had been encountered in transferring completed projects to the national health department. What had not been done, or could not be done, was to transfer with completed projects the privileges and immunities enjoyed by the *Servicio* but denied to the national health department. By virtue of the basic agreement between the ministry of health and the Institute, the *Servicio* had relative freedom to hire and fire personnel and was exempt from many bureaucratic controls on administration and utilization of funds. The national health department, recognizing its inability to equal the effectiveness of the *Servicio*, had therefore been reluctant to assume responsibility for certain of the major health and sanitation projects. A *Servicio* responsibility for many years, these services should be relinquished; yet, it appears that for the present the *Servicio* will be required to continue their operation.

Conclusions

The indigenous health organizations in Latin America usually, but not invariably, have been developed and stabilized as a result of the *Servicio* projects. More attention to planning might well have mitigated some shortcomings, however.

The rate at which programs and methods were incorporated into the permanent public health structure has been generally satisfac-

tory, although incomplete planning sometimes has retarded the process.

Although the extent to which health habits and practices of the people have been influenced is difficult to evaluate precisely, many of the situations studied indicate that the people's habits and practices were, in fact, favorably influenced.

National Advisory Health Councils

A survey of health program planning cannot be limited to planning done by the *Servicios* since health programs in Latin America are for the most part formulated and executed by the constituted health authorities of the national, state, and local governments. In some countries private agencies play a major role in health activities. In almost all the countries, the Red Cross conducts a health program that supplements that of the government.

In certain countries the entire campaign against tuberculosis is the responsibility of a private or voluntary agency. Notable in this regard is the *Liga Ecuatoriana Anti-Tuberculosis* which maintains in various parts of the country 23 dispensaries and 8 hospitals with a total of 2,000 beds. Not infrequently the hospitals, or a large portion of them, are operated by a voluntary organization termed *Beneficencia*. These voluntary agencies are usually subsidized by government, and in addition they benefit from lotteries or special taxes authorized by government.

Because the ultimate responsibility for all health programs rests essentially with the government, considerable advantage could result from joint planning. Moreover, since the success of health programs, whether official or voluntary, depends to a considerable extent upon an alert and informed public, it would appear desirable for the public to be brought into a relationship with the official planners.

A mechanism to secure both the benefits of coordination and of broad public support of health programs would be a national health council, advisory in character. Such a council could be created by the ministry of health. Membership should include representatives from all the national agencies concerned with health, the voluntary organizations, the uni-

versities, and the technical schools, as well as persons from philanthropy, business, finance, and industry. The council's membership would thus represent a cross section of society of the nation and would embrace the planners, providers, and consumers of health programs.

The advisory character of the council should be maintained. It should have no executive, financial, or administrative responsibilities. However, because of its composition, its advice should carry great prestige. Health plans of government might thereby be greatly strengthened.

In countries where governments may on occasion change suddenly, a national advisory health council would have the added value of providing a link between the old and the new, giving greater continuity to health activities, especially planning.

National and International Conferences

A number of agencies in addition to the Institute of Inter-American Affairs are engaged in cooperative health programs with many of the governments of the American Republics. Important ones are the Pan American Sanitary Bureau, which serves as the regional office of the World Health Organization; the United Nations Children's Fund; the Kellogg Foundation; and the Rockefeller Foundation.

The interests of these several agencies are not so very different, one from the other, and their cooperative programs in the American Republics are in consequence closely related. In Chile, three of these agencies—the Kellogg Foundation, the Rockefeller Foundation, and the Institute of Inter-American Affairs—cooperated with the government in the development of nursing education and medical education. The latter two agencies worked with the government in establishing the National School of Public Health in Santiago.

The National School of Nursing of the Central University in Quito, Ecuador, is another example of joint action. The PASB, the IIAA and the Rockefeller Foundation joined forces in aiding the Ministry of Health in the development of this institution. Aid included the provision of two American nurses to help with

organization and guidance in the early years, the reconstruction of a building to house the school, the purchase of equipment, some assistance in the initial cost of operation, and provision for a consultation service.

In almost every Latin American country examples could be cited of participation by more than one of these agencies in the national health program. The fact that so little real overlap and duplication of program activities was observed is a tribute to those responsible locally. However, it must be recognized that there is a degree of competition among the agencies to secure cooperative projects and funds to finance them, with the consequent danger of adverse effect upon the national health budget.

It would be a part of good planning for these cooperating health agencies and the several national health services to adopt some device for protection against possible adverse effects from uncoordinated program developments. More important would be the positive benefits that could accrue from the application of the joint resources in technical skills and funds toward a common objective. To this end, it is suggested that clearinghouse conferences be established at both the international and national levels. At these conferences an opportunity would be provided each agency to describe its program interests and its plans for project development. Opportunities, if any, for joint action would become apparent.

A beginning at the international level has already been made in Washington, under the chairmanship of the director of WHO-PASB. Monthly meetings are being held with representatives from PASB, the IIAA, the Division of International Health of the Public Health Service, and other agencies. These have already proved useful.

A similar arrangement seems desirable for each American Republic where more than one foreign agency is cooperating. Since all international health agencies enter into bilateral agreements with the various governments in developing programs, the leadership in establishing clearinghouse conferences at the national level should be taken by the health authorities of each country.

technical publications

Fifty-first Annual Conference of the Surgeon General, Public Health Service, Chief, Children's Bureau, With State and Territorial Health Officers

Public Health Service Publication No. 307. 1953. 75 pages. Available on request to the Division of State Grants, Public Health Service, Washington 25, D. C.

The fifty-first annual conference of the Surgeon General, Public Health Service, and chief, Children's Bureau with the State and Territorial health officers, State mental health authorities, and representatives of State hospital survey and construction agencies was held December 8-11, 1952, in Washington. This publication constitutes the proceedings of the conference and includes the complete text of addresses given in the general sessions and the recommendations of the committees on environmental sanitation, Federal relations, hospitals, infectious diseases, maternal and child health, mental health, and special health and medical services. [Highlights of major addresses were published in *Public Health Reports*, February 1953, pp. 174-190.]

Health Manpower Source Book

Section 2. Nursing Personnel

Public Health Service Publication No. 263. 1953. Prepared by Helen G. Tibbetts and Eugene Levine. 88 pages; tables. 40 cents.

The second in a series of comprehensive source books on health manpower, this publication covers 50 years of nursing and contains 56 tables of data on nursing personnel, each preceded by a discussion of the background and methods used to gather the data.

The first part of the book deals with the general distribution of professional nurses; their age, sex, and marital status; licensure; and education. The second part presents data on the licensure and training of practical nurses. The last part of the book, fields of practice, gives comparative data for six fields of nursing and details on public health, industrial, and hospital nursing personnel.

A summary of trends is given at the beginning of the book. As of 1950 there were 249 active graduate nurses per 100,000 population in the United States. In 1910 the ratio was 55 per 100,000. In 1920 active graduate nurses were fewer than physicians; since 1930 they have outnumbered physicians. Since 1900 the proportion of men among active graduate and student professional nurses has declined from 6 percent to 2 percent, although their number has increased from 758 in 1900 to 11,320 in 1950.

Home Accident Prevention A Guide for Health Workers

Public Health Service Publication No. 261. 1953. 75 pages. 30 cents.

Accepting the thesis that the majority of home accidents can be prevented, this booklet presents an outline and guide to enable health workers to study and understand the chief causes of accidents in the home and to take measures that may prevent them. The material is prepared for the professional health worker on the premise that leadership in home accident prevention program development should be assumed by this group.

The problem of home accident prevention is defined in relation to other health needs. Factors, environmental and human, tending to cause accidents and their interrelationships are outlined. Suggested activities by agency, group, or individual for better understanding and treatment of

the problem are presented throughout the guide.

A 20-page list of selected references, coded to designate the various classifications of the content material, and a 2-page list of films and filmstrips are included.

Six Food Exchange Lists for Variety in Meal Planning

Public Health Service Publication No. 326. 1953. 4-fold leaflet. Available on request to Division of Chronic Disease and Tuberculosis, Public Health Service, Washington 25, D. C.

Selection of a varied diet, especially for the diabetic person, is made easier by the use of the six food exchange lists developed by committees of the American Diabetes Association and the American Dietetic Association, in cooperation with the Public Health Service. The leaflet sets forth six lists of food items—milk, vegetables, fruits, bread, meat, and fat. All foods within the same list contain approximately equal amounts of carbohydrate, protein, fat, and calories, and thus one food in a list may be substituted for another food on the same list. For example, on list 4 one small potato may be used in place of a slice of bread.

This leaflet does not give a diet prescription. A physician should prescribe the amounts of food and the number of exchanges allowed each day. The food exchange lists facilitate selection of a variety of foods for a diet that is being followed.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Training Courses in Prothrombin Time Determinations

Clinical research during the past decade has shown that the proper use of anticoagulant drugs can reduce morbidity and mortality from thrombosis and embolism. Safe and effective use of these anticoagulants, however, requires a more complete laboratory control than is necessary for most drugs, since their safe administration depends upon reliable laboratory data for control of the dosage.

Refresher courses in this technique are offered by the heart section, Division of Chronic Disease and Tuberculosis, Public Health Service, with the sponsorship and/or cooperation of the various State health departments, American Heart Association, pathology societies, and other interested organizations. The purpose is to present to medical technicians the critique of performing accurate, reproducible prothrombin time determinations, and to afford an opportunity for supervised laboratory experience with these methods.

Services and materials available through the regional offices of the Department of Health, Education, and Welfare include a brief description of the course; services of a physician-director and a technician-instructor in planning and conducting the training course; a teaching manual; and laboratory manuals for participants.

Since the pilot technician-training program began in Massachusetts in 1950, refresher courses have been provided in 12 States and 1 Territory (see table). In at least 9 other States, technician-training is now being provided on a long-range basis by local institutions.

State	Number technicians trained	Number laboratories or hospitals represented	State	Number technicians trained	Number laboratories or hospitals represented
Arkansas.....	22	16	North Carolina....	47	38
Florida.....	88	64	South Carolina....	14	11
Idaho.....	6	5	Tennessee.....	10	8
Kansas.....	28	26	Utah.....	23	13
Maryland.....	1	1	Puerto Rico.....	15	11
Massachusetts.....	71	55			
Montana.....	15	9	Total.....	366	279
New Jersey.....	26	22			

NOTE: At the time this table was prepared, a series of courses was being given in Virginia to about 18 technicians.

The Occurrence of Influenza In the United States, 1952-53

By DORLAND J. DAVIS, M.D., and CARL C. DAUER, M.D.

UNDER THE SPONSORSHIP of the World Health Organization, a worldwide effort to improve the reporting and epidemiological study of influenza and the exchange of virus strains has been in effect for the last 6 years.

In the United States the WHO Influenza Study Program has been ably supported by investigators and diagnostic laboratories of State and Federal agencies, universities, the Department of Defense, and those associated with the Commission on Influenza of the Armed Forces Epidemiological Board. A previous report described the organization and specific objectives of the program and listed the participating laboratories (1). The present report will summarize the information obtained by these investigators and the mortality experience as reported by State and city health officers for the period from July 1, 1952, to June 30, 1953.

Dr. Davis is executive secretary of the Influenza Information Center, WHO Influenza Study Program in the United States, National Institutes of Health, Public Health Service. He is also chief of the influenza unit in the laboratory of infectious diseases, National Microbiological Institute of the Public Health Service.

Dr. Dauer is medical adviser to the chief of the National Office of Vital Statistics, Public Health Service.

Investigations of recent years have shown that there has been a progressive change in the antigenic pattern of strains of influenza virus, and attempts have been made to indicate this change in the designations of types, such as the widely used term influenza A'. These designations have been convenient but not completely satisfactory. The WHO Expert Committee on Influenza (2) recommends:

the subdivision of the influenza A virus into the following main groups, which are named after their prototype viruses and the date of their isolation:

WS (1933)

PR8 (1934)

FM1 (1947)

The recent A strains, of which FW/1/50 and A/England/1/51 are examples, though different from FM1, are not as divergent as the other main groups and are therefore considered to fall within the FM1 (1947) group. There is also a heterogeneous group of swine influenza viruses related antigenically to the human influenza A viruses.

The influenza B viruses should be subdivided into groups with the general characteristics of:

Lee (1940)

Bon (1943)

The most recent influenza B strains (1952) appear to diverge from Bon, and it may be found on the basis of future experience that further groups must be created.

In influenza C only one antigenic group is so far known, of which 1233 (1947) is the prototype.

Thus, the strains recovered during the 1952-53 season and referred to as A' because of their similarity to the FW/1/50 of FM1 strains,

which were used most widely for diagnosis, will be designated as belonging to the group FM1 (1947) in this report. Final studies may justify the designation of the 1953 strains as a separate group, but the recommendations of the WHO expert committee will be followed in the present report. Since various influenza strains were used as antigens for the hemagglutination inhibition and complement fixation tests by the different collaborating laboratories, results of serologic diagnoses will be recorded in tables 1 and 2 as either type A or type B with no attempt to differentiate further between strains.

Occurrence of the Disease

No outbreaks of influenza were reported within the United States during the summer and fall of 1952. There were, however, a few cases diagnosed serologically as influenza B and a few cases diagnosed as influenza A (FM1 (1947)) during October and November in military installations in the United States. A small outbreak of influenza-like disease occurred during the latter part of November at a military installation in the Philippine Islands, and several of the cases were subsequently specifically diagnosed as influenza A (FM1 (1947)).

In early December 1952, a definite increase in the incidence of acute respiratory disease occurred among military personnel at Fort Leonard Wood, Mo. The number of cases increased sharply and had reached a relatively high incidence by the last week of December. At this time an influenza A virus closely related to A/FW/1/50 was recovered from a significant number of cases, and serologic studies gave further evidence of influenza infection. However, not all cases studied were established as influenza, and the possibility of the concurrent presence of another disease was studied by military investigators.

During the same week in December, State health officials reported an influenza-like disease in Pueblo, Colo., and in nearby cities. This also was subsequently confirmed by laboratory tests as influenza A (FM1 (1947)). In Watanga County, N. C., a sharp epidemic with a high incidence rate was reported during the same week and shown to be influenza of the same type. Reports from the military services

indicated an increased number of cases of influenza in the Far East in late November and December, principally in Okinawa and Japan.

January 1953 Epidemic

During the first week of January 1953, influenza occurred in epidemic form in Iowa, Indiana, South Dakota, Oklahoma, Missouri, and Florida. By the second and third weeks of the month the outbreaks were reported from most of the middle western and southern States. Texas was particularly affected, and a large number of cases was reported. Subsequent reports indicate that influenza virus A (FM1 (1947)) was frequently recovered. The southeastern part of the United States also was affected, and the disease was specifically diagnosed in the Washington, D. C., area, Norfolk, Va., and other parts of Virginia. The northeast and New England area had a few localized outbreaks particularly noticeable in military installations, but the incidence generally was not high. On the west coast, the incidence was slightly increased but did not approach that of the midwest. Sharp outbreaks in the military and civilian population in Alaska began the first week of January and persisted throughout the month. Toward the end of January the incidence of disease in affected military installations fell off although in civilian populations incidence remained high, and new areas within the midwest and south reported outbreaks. In many of these areas schools were closed because of the illness among pupils and teachers. By the end of the month, the incidence was declining in most areas.

In the early part of February 1953, the incidence continued to decline, and during the remainder of February and early in March, a few scattered outbreaks of influenza occurred, particularly in schools and institutions, not only in the midwest and the south but also in the northeast and the west. No outbreaks have been reported in the United States since that time.

The total number of isolations of influenza virus and positive serologic tests reported from all participating laboratories in the continental United States and the Territory of Alaska by date of onset or collection for each month are presented in table 1. In addition, 16 strains of

Deaths From Influenza and Pneumonia for 58 Selected Cities; by Weeks

influenza A were recovered and 355 positive serologic tests for influenza A were made for which the month of onset or collection date was not exactly known although presumably it was during the period of highest incidence. Not shown in the table is a record of a case of influenza C diagnosed by the complement fixation test which occurred in Chicago during December 1952.

These data indicate that influenza A (FM1 (1947)) was almost exclusively the cause of the epidemic and that only a few sporadic influenza B infections occurred. That January was the month of highest incidence of specifically diagnosed cases conforms to the reports of the occurrence of outbreak received from health officers.

Dr. Clayton G. Loosli of the collaborating laboratory at the University of Chicago has submitted the following observations on the clinical features of the disease:

Although generally reported as mild, influenza infections produced in some cases severe prostration. They were sudden in onset beginning with high fever, marked headache, malaise, muscle aches and pains, and

dry cough. Some had photophobia. A few having etiological or serologic evidence of influenza also had symptoms of the common cold, sinusitis or a pneumonitis. Three cases with typical findings of pneumococcal pneumonia due to pneumococcus types I, II or III also had etiological or serologic evidence of influenza. The average hospital stay of uncomplicated influenza was approximately 5 days.

Mortality From Influenza

As shown in the accompanying chart, the number of deaths from influenza and pneumonia in 58 selected cities, which are located in all parts of the United States, began to increase early in January 1953. These diagnoses are based on records of death certificates and do not represent laboratory confirmed cases of influenza. The peak was reached in early February; after that time the number gradually declined. In the 3 years immediately preceding 1953, an increase in deaths from influenza and pneumonia did not begin until late in February, and in none of these years was the number reported as great as it was in 1953.

Data from 8 of the 58 cities were obtained on

Table 1. Isolations of influenza virus and positive serologic tests (any technique) reported by civilian and military laboratories participating in the United States and Alaska

Month and year	Isolation of virus		Positive serologic tests	
	A	B	A	B
December 1952.....	10	-----	29	4
January 1953.....	237	1	1, 148	22
February 1953.....	105	-----	1, 059	9
March 1953.....	27	-----	377	1
April 1953.....	-----	-----	69	3
May 1953.....	-----	-----	21	-----
Total.....	379	1	2, 703	39

numbers of deaths from influenza and pneumonia during January and February 1953 for broad age groups. The deaths from influenza and pneumonia combined showed the following distribution: 22.7 percent were in persons under 15 years; 1.3 percent were in the 15- to 24-year group; 28.4 percent in the 25- to 64-year group; and 47.5 percent were 65 years and over. The percentage distribution of influenza deaths was 7.7, 2.3, 20.9, and 69.0, respectively, for the above

Table 2. Estimated death rates per 100,000 population for the United States from all causes, and from influenza, pneumonia, and major cardiovascular-renal diseases, for certain months of 1951, 1952, and 1953

Month and year	All causes	Influenza	Pneumonia	Cardiovascular-renal diseases
December 1952.....	1, 014. 2	3. 4	31. 4	547. 5
January 1953.....	1, 083. 1	17. 1	48. 4	590. 7
February 1953.....	1, 131. 6	26. 4	49. 5	610. 7
March 1953.....	1, 021. 2	13. 6	34. 0	561. 7
April 1953.....	955. 7	5. 0	26. 0	524. 2
December 1951.....	1, 027. 2	3. 1	31. 0	551. 7
January 1952.....	1, 003. 5	4. 6	36. 6	544. 3
February 1952.....	1, 015. 6	8. 4	34. 7	538. 0
March 1952.....	1, 059. 5	12. 3	41. 0	568. 4
April 1952.....	982. 4	5. 4	31. 5	530. 5

age groups. These data indicate that persons in the older age groups felt the impact of the influenza epidemic more than younger persons.

The figures in table 2 have been taken from the *Monthly Vital Statistics Reports* of the National Office of Vital Statistics, Public Health Service. They show the estimated death rates for the United States from all causes; and from influenza, pneumonia, and major cardiovascular-renal diseases, based on a 10-percent sample; and they cover the periods when influenza was prevalent in 1952 and 1953. Although these data are subject to random sampling errors, they show that the number of deaths from all causes and from pneumonia and cardiovascular-renal diseases increased moderately and that those from influenza increased markedly during the period when influenza was known to be prevalent. The increases were greater in 1953 than in 1952; this is consistent with the data for 58 cities shown on page 1143.

Antigenic Analysis of 1953 Strains

The WHO Strain Study Center for the Americas, located in the laboratory of Dr. T. P. Magill, State University Medical Center at New York, Brooklyn, N. Y., has studied the antigenic characteristics of 24 strains of influenza virus isolated late in 1952 and in 1953 by various workers. Hemagglutination inhibition tests were performed with these strains and cholera-filtrate treated rabbit antisera which were prepared against 8 chronologically separated strains:

A/PR8/34.	A/FW/1/50.
A/New York/41	A/England/1/51.
(Coyle).	A/New York/1/53.
A/FM1/47.	A/Ohio/1/53.
A/Nederland/1/49.	

These tests showed clearly that the recently isolated strains were influenza A virus but were different antigenically from previously isolated ones. The 1952-53 strains possessed some antigenic components which were undetectable or inconspicuous in the older strains. They differed in practically the same degree from A/FM1/47, the prototype of the A' strains, as the latter differs from the PR8 strain in 1934. This adds further evidence to the concept of an apparently orderly alteration in the antigenic

The Virus, the Cell, and the Potentialities of Influenza

"I have spoken throughout as if influenza virus were no more than a laboratory tool, a subtle probe with which to explore the finer structure and functioning of the living cell. It would not be fitting, however, to end this lecture without reminding you that influenza virus is also an important agent of disease. It is a virus which even in 1951 killed heavily amongst the old people of Europe and in 1918-19 generated the third great plague of recorded history. Of all virus diseases influenza is probably that in which mutational changes in the virus are of greatest human importance. We can only guess what type of virus was responsible in 1918-19 and what changes took place during the course of the pandemic. But even in the period since the human virus was first isolated in 1933 there have been striking changes in the immunological character of both influenza A and B viruses. Some of us believe that the influenza virus' chief means of survival

is its capacity for constant mutation to new serological patterns, and those of us who have had anything to do with the production of influenza vaccines know very well how that capacity can nullify the most painstaking work. Infectious disease today has lost most of its terrors, and in America at least the peaks of mortality that always marks the passage of an influenza epidemic are becoming smaller. But no one yet can say whether or when we shall see another pandemic outbreak of influenza. Until we know the answer to that question we should not be too complacent about our powers to deal with acute infectious disease. Even the most academic-seeming of investigations, like those I have described, may one day become matters of life and death."

—Sir F. MACFARLANE BURNET, F. R. S.,
in the Second R. E. Dyer Lecture, 1952,
Public Health Service Publication No. 328.

composition of influenza viruses by the appearance or dominance of new components and the suppression or disappearance of others as determined by this method of analysis.

Influenza Outside the United States

From outbreaks of influenza in South Africa during June 1952 and on Bahrein Island during September, strains of influenza A (FM1 (1947)) were isolated and identified by the laboratories cooperating in the World Health Organization study. Influenza was next reported in the Far East, Japan, and the Philippine Islands in early December 1952. Approximately coincident with highest occurrence of the disease in the United States during January 1953, outbreaks appeared in France, Germany, and southern England, later extending to the Scandinavian countries, Switzerland, and Austria, and to scattered parts of Europe. The isolated strains were all influenza A (FM1 (1947)), similar to those isolated in 1951 and to those

recovered in the United States during January 1953.

Later in 1953, during May, June, and July, influenza appeared in the Central American and South American countries in large outbreaks, but virus strains have not yet been completely studied. Mortality reports indicate that the death rates in European and South American countries were similar to those in the United States with some increase in the death rate from influenza and pneumonia, but the increase was largely confined to the older age groups of the population.

Comments and Conclusions

The broad picture presented here shows that influenza A was widespread throughout the Americas and Europe during the 1953 season, although some large areas were spared. It is to be remembered that during the previous season in 1952, influenza B was locally prevalent although not of such high incidence in North

America and Europe, and influenza A was practically absent. During the winter 1950-51, influenza A caused serious epidemics in northern England, particularly in Liverpool, and in northern Europe during December and January, and it was also occurring in the northeastern part of the United States. In the 1953 experience, the highest incidence in the United States was in the midwest and the south. The northeastern part which had been affected 2 years previously was largely spared with the exception of some military installations.

The mortality data here presented indicate that a significant number of deaths resulted from influenza and that this disease is still an important cause of deaths. This is true in spite of the availability of antibiotics and their presumed widespread use in the treatment of severe respiratory infections. Perhaps too

complete confidence in the ability of the antibiotics to reduce deaths from pneumonia, and thus alleviate the chief danger from influenza, may not be justified.

. . .

Current lists of laboratories and observers participating in the Influenza Study Program in the United States may be obtained from the Influenza Information Center, National Institutes of Health, Public Health Service, Bethesda, Md.

Labeling Salt in Food

Two actions to protect persons suffering from some types of heart disease, or from high blood pressure, who are on "low-sodium" or "low-salt" diets have been taken by the Food and Drug Administration of the Department of Health, Education, and Welfare.

The aim of these actions is to improve the labeling of special dietary foods, and of certain frozen vegetables commonly used in low-salt diets, so that patients and physicians will be better able to calculate the sodium intake from such foods. In one action, the Department published a statement of policy in the Federal Register, to the effect that it will henceforth expect all labels of frozen vegetables to declare the presence of salt whether added directly or indirectly to these products.

FDA explained that frozen vegetables are quite commonly supposed to be salt-free, and on that account are largely used in low-salt diets. Actually, salt brine is used in the preparation of

certain of these vegetables, particularly frozen peas and frozen lima beans, as a means of quality separation (the younger and more tender peas or beans will float in the brine). This process may add a substantial amount of salt to the frozen product, which would be of significance to persons seeking to restrict their salt intake.

In the second action, the Secretary of the Department of Health, Education, and Welfare gave notice in the Federal Register that public hearings will be started on December 15, 1953, in Washington, to amend the FDA dietary food labeling regulations so as to require label declaration of sodium in low-sodium foods on the basis of their sodium content in milligrams of sodium per 100 gm. (roughly one small serving) of the food. FDA said that the declaration of sodium content on this basis conforms with the recommendation of the American Heart Association and the Council on Foods and Nutrition of the American Medical Association.

New Orientation in the Teaching of Preventive Medicine

By W. PALMER DEARING, M.D.

ALL OF US in this world conference on medical education are concerned with methods of equipping the physician of tomorrow for his full role in raising the level of health of the people he serves. That role will obviously vary from place to place and from time to time, depending on the particular health problems that predominate in a given country and on the capability of medical knowledge to solve those problems.

No system of medical science and thought in the world today can claim the capacity to solve all health problems. Some diseases of world-wide prevalence, such as malaria and enteric infections, cannot be dealt with effectively without the application of engineering and sanitary science. Others, such as the nutritional deficiency diseases, cannot be dealt with effectively

without attention to economic and social conditions.

Moreover, since no physician can function apart from the society in which he lives, his role will depend upon the degree of acceptance which the people give him. H. Cullumbine (1) found, for example, in his recent survey in Ceylon, that practitioners trained in Western medicine and those trained in the Ayurvedic systems were each called upon to treat about one-fourth of the illnesses reported by some 18,000 families, and that 1 in every 20 sick persons was receiving treatment from both types. Dr. Cullumbine comments: "Patients with illnesses which Western medicine has shown it can control are placed in the care of Western practitioners; where such superiority on the part of Western medical science has still to be conclu-

Dr. Dearing has been Deputy Surgeon General of the Public Health Service since 1948 and a commissioned officer of the Service since 1934. He began his public health work as an assistant in epidemiology at the Harvard University School of Public Health working with the late Dr. Milton J. Rosenau in teaching preventive medicine and hygiene to medical students. His assignments with the Public Health Service have included studies in tuberculosis epidemiology under the late Dr. L. L. Lumsden and early work with small-film X-rays. In 1945 he was deputy chief of the Division of Public Health Methods and in 1946 was named chief of the Division of Commissioned Officers in which post he was instrumental in undertaking a complete over-

hauling of policies and programs for recruitment, professional training, and assignment. During World War II he served as chief medical officer of the Office of Civilian Defense and as personnel chief of the Health Division, United Nations Relief and Rehabilitation Administration.

This paper was presented before the First World Conference on Medical Education at London, August 25, 1953. The conference, on the theme "standards of undergraduate medical education," was held under the auspices of the World Medical Association in collaboration with the World Health Organization, the Council for Organization of Medical Sciences, and the International Association of Universities.

sively proved to the layman, then help from the traditional Ayurvedic system is sought." I venture to predict that a similar study in any other society, Western or Eastern, would reveal a comparable independence on the part of patients in their choice of physician.

Terminology differs in England and the United States, as all of us are aware. The British physician refers to "social medicine"—the American, to "preventive medicine." Recognizing the terms as interchangeable, I will use the nomenclature of my own land.

The Need for Orientation

One of our philosophers, Professor Theodore M. Greenc, of Yale University, describes the ideal doctor as "one who understands the human body as completely as possible in the light of all relevant sciences, who understands the human mind and its working as well as possible in the light of all relevant modern psychology and psychiatry, and who in addition understands a human being in his full potential spiritual stature" (2). In the light of modern health problems, I would add to this the requirement of an understanding of the physical and social environments in which his patients live.

If we in this conference can agree on these attributes of an ideal physician, we will readily discern the need for new orientation in the teaching of preventive medicine. For, although medical education today does a superlative job in giving the medical student a thorough grounding in anatomical and functional pathology, and skill in diagnosis and therapy, most people agree that it falls short in developing the deep understanding of human nature and human behavior which the physician must have if he is to practice prevention as well as to cure; to promote health as well as treat disease. Likewise, the medical school too often fails to prepare the student to apply the universal principles he has learned in settings other than that of the completely equipped and fully staffed teaching hospital. The medical school, therefore, needs to be as well grounded in the social milieu in which its graduates will practice as in the latest findings of medical science.

This means that no standard pattern for medical education can be applicable in all times and

places. What society requires of a medical school in Edinburgh or Boston will not necessarily meet the needs of society in Thailand or Lambarene. Yet the faculties, students, and practitioners in all these widely differing societies have much to share in knowledge and experiences.

Some Unsolved Problems

In this spirit of exchanging experience, I shall talk of our efforts in the United States to reorient certain aspects of medical education from the standpoint of preventive medicine, and I shall discuss some of the unsolved problems in my country.

Like my colleagues in public health work, I know that preventive medicine is not the exclusive field of the public health specialist. The increasing problem of cardiovascular diseases and cancer, of diabetes, rheumatic conditions, and mental disorders cannot be controlled by environmental sanitation, by immunization, or by quarantine. The recent shifts in the major causes of death and disability require the practicing physician to use preventive techniques in combating the health problems of a population whose proportion of old people is increasing. He must use all available health resources in a community to achieve early case finding, prompt diagnosis and followup treatment, and rehabilitation services—all contributing to prevention insofar as they forestall continuing disability and premature death.

Public health can be thought of as the organized application of preventive medicine, and traditionally it has been concerned with the prevention of health threats to the community as a whole. The private physician, when he is consulted by a person in an acute phase of illness, tends to be concerned primarily with restoration of the health of the individual.

Medicine has made phenomenal progress in diagnostic and therapeutic techniques, and medical education is geared to introduce the student without delay to new developments in these techniques. The medical schools have well-established departments in the basic and clinical sciences staffed by specialists who keep abreast of current advances in their fields. What is lacking is equal concern to advance

the knowledge and application of preventive measures in controlling the conditions that undermine health.

Social Changes Affecting Health

During the last half century revolutionary changes have occurred in community life in the United States. In place of the large stable family in a small, self-contained community, where social relationships are well established and all age groups have a place, we find smaller family groups that move frequently from place to place and maintain few continuing contacts with their neighbors and relatives. Earlier dependence on grandparents and aunts and cousins in time of illness or economic distress is being replaced by dependence on the community and its institutions.

Concurrently, methods of production have vastly improved, making possible higher standards of living. Education at all levels has become more widely available. Regional differences and barriers are diminishing under the impact of rapid communications. The interdependence of the welfare of the individual and the community is manifested in the growth of a multiplicity of community hospitals, public health departments, social welfare agencies, and systems of social insurance which have developed to meet newly identified needs.

Conditions of work, increased leisure time, and diversified recreational activity also manifest sharp contrasts with the past. High tension in both work and play and problems of personal relationships produce or intensify not only the emotional but also many of the physical disorders that are prevalent today. Prevention and treatment of these disorders require knowledge of the interplay of personal and environmental forces which condition man's behavior and his health.

Moreover, there is need for a new look at the modern environment. Preventive medicine research in the past found the sources of many infectious diseases in the insanitary environment, and today it is necessary to study the industrial and urban influence as the possible source of continuing and new health hazards which may be controlled on a community-wide basis. Pollution of the air and water by industrial wastes, substandard housing, and ex-

posure to new chemicals of unknown toxicity are all parts of the modern environment which contribute to the major health problems of the United States.

The Physician's Role in Preventive Medicine

The changes in American life have been accompanied by parallel changes in medical practice. Forty years ago, the family practitioner had intimate personal knowledge of his patients and their families. Today, however, he is yielding ground to relatively impersonal hospital practice by specialists, each often concerned with but a fraction of the total problem confronting the patient. At the same time, increased scientific knowledge and public understanding of health requirements have broadened the demands upon the medical profession.

Today's physician should be equipped to deal with the effects of the total environment on health—the social environment as well as the physical. He should be prepared to plan the total health care of the patient, preventive as well as therapeutic. Exclusive attention to a restricted range of biological phenomena can no longer be considered good medical practice.

There are many evidences that undergraduate medical education in the United States today falls short of preparing physicians for their full role in health maintenance and the prevention of disease. A conference on psychiatry and medical education, held in 1951, concluded that there is a concerted demand that physicians assume responsibility for the proper practice of preventive medicine. A questionnaire distributed to 3,500 community leaders throughout the United States by the conference's Preparatory Commission brought some 700 opinions that physicians of today are not giving the service expected of them. Some of the specific statements were: "They do not have time or inclination to listen to and consider the patient's feelings." "They do not have enough knowledge of emotional problems and socioeconomic family backgrounds." "In treating physical disease, they are often out of touch with the personal and social problems and pressures of the rank and file" (3). The conference report stresses the need for a greater mutual understanding between individuals and their

personal physicians and a greater degree of collaboration in the promotion of health.

Accurate diagnosis and prescription of remedies and treatment regimens taken by themselves may be of little avail in preventing illness or its recurrence. For example, a physician writes on Mrs. X's record: "Malnutrition slight. Inadequate intake due to poverty. Treatment: codliver oil tablets. Return in 1 month." The social worker, who has been in direct touch not only with Mrs. X but also with her family, has a broader view of the situation and, I think you will agree, a more constructive approach to treatment. She has studied the family budget and knows its limitations. She is helping Mrs. X to find a cheaper apartment nearer her husband's work in order to stretch the earnings. The social worker is thus taking action to prevent serious malnutrition by helping the family to have more money and food.

Another illustration comes from the family adviser service in the University of Pennsylvania Medical School. Mrs. G had high blood pressure and according to the family had no other health problems except that her father-in-law was ailing and irritable, and the children might be better off if they could play outdoors. The student health adviser's sympathetic talks with the father-in-law induced the latter to undergo regular treatment for his pernicious anemia. The health adviser also found a nearby church whose minister was delighted to have the churchyard used as a playground. Mrs. G's blood pressure, to her surprise, kept going down. The medical student who served as the family health adviser might have needed many years of experience in practice to learn for himself that high blood pressure can sometimes be alleviated by treating some other person's ailments and by getting a playground for the children (4).

I am sure that the experience of my colleagues in other parts of the world leads to the same conclusion we are arriving at in the United States: that the diversity of specialized medical and related services available in the modern community requires today's medical student to have knowledge of all community resources for preventive medicine. He must learn how to establish working relationships among a variety of specialized personnel and facilities if people

are to receive the services needed to prevent and treat illness and to return patients to useful activity.

In addition to his concern with individual patients and their families, the physician should also be prepared to assume leadership in the attack which the community makes upon health problems through the organization and operation of community health services. If medical schools are to do a good job in training the physicians for this leadership role, they must give attention to the health problems of communities as such. Medical schools as well as their graduates should realize that, if physicians relegate themselves to the role of medical technician, there is real danger that leadership in organizing medical and related services which the public demands will, by default, be forced upon others.

Strengthening Communication and Teamwork

Dr. Alan Gregg, in an address at the annual meeting of the Association of American Medical Colleges in 1952 (5), made an eloquent plea for better communication among the numerous specialists in medicine and between medicine as a whole and the public at large. He draws a striking analogy between the paralysis, necrosis, and other disturbances of function which result from disruption of the communication systems within the human body—the lymphatics, the blood vessels, and the nerves—and the eventual fate of medicine if some way is not found to foster communications between the "steadily proliferating subdivisions, bailiwicks, precincts, disciplines, and specialties." I would like to elaborate Dr. Gregg's thought to identify the social sciences—sociology, anthropology, and economics—as disciplines with which medicine must specifically improve communication.

These questions of communication and teamwork are the active concern of medical educators. The Association of American Medical Colleges joined with the American Psychiatric Association in organizing and conducting two conferences on psychiatry and medical education, one of which was mentioned earlier. The Association of American Medical Colleges similarly sponsored and took an active part in a

Joint Conference on the Teaching of Preventive Medicine. The experience gained in these three conferences has led the Association of American Medical Colleges to plan a series of teaching institutes to cover the entire structure of medical education.

Dr. George Packer Berry, dean of Harvard Medical School and past president of the association, reports that these institutes, to be held at annual intervals, will include sessions to consider the interrelationships in teaching among groups of the basic sciences, medical ecology, clinical teaching including the internship, and specialty training and the continuing education of the physician (6). As a device to focus the interest of the several medical departments on methods of integrating their work, these institutes will promote mutual understanding and community of purpose among the various specialized subdivisions of medical education and the related institutions in the community.

A national Commission on Chronic Illness, established in 1949, held a conference on the preventive aspects of chronic disease in 1951 (7). All interested professional groups were represented. In addition to medical education, health and social welfare agencies and the public were represented. That conference produced an inventory of current scientific knowledge concerning the nature and prevention of the chronic diseases. Considered also was the problem of improving care for the chronically ill, covering such fields as professional education and organization and coordination of services. Medical educators and physicians who participate in such conferences contribute sound medical guidance. At the same time they gain a deeper insight into the skills and potential contributions of other professions in dealing with common problems.

A national conference on cardiovascular disease in 1950 (8), in addition to sections on technical knowledge and research, included important committees on community services for education and prevention, on case finding and epidemiology, on facilities and services for treatment and management, and on integration of community services. Represented in these committees were medical educators, cardiologists, health officers, hospital directors, and commu-

nity service agencies. The professional education committee dwelt upon the importance of including broad knowledge of the techniques and resources for prevention in the teaching programs for every profession.

In the same year a national conference on aging and its problems (9) considered a wide variety of social and economic factors involved in satisfactory health maintenance, work, recreation, religious activity, and living arrangements for the aging population. A section of that conference also stressed the need for giving professional personnel a clearer insight into the total phenomenon of aging in addition to their specialized technical instruction.

These and other conferences, groups, and seminars have contributed materially to the complex task of pulling together the viewpoints of traditional and emerging specialties in health and related fields. They have aided in identifying common interests and purposes; and they have set a base for the interchange of concepts and ideas which we know to be important to the preventive medicine component of modern medical education.

Strengthening Education in Preventive Medicine

Let us now consider some of the specific steps that some institutions are taking to meet the challenges we have been discussing. Methods of getting the student to see patients as individuals with families and jobs; of getting social science skills and viewpoints into medical schools; and of getting medical schools and their communities into more effective relationship with each other are being actively sought.

We are trying, for example, to restore some of the values formerly realized in the apprenticeship training on which medical education was once largely based. Obviously, we do not want simply to return to the past or to discard the advances of the last century. We do want, however, to improve methods by which the medical school itself can give the student an opportunity to complement his specialized training with an understanding of the role of the family physician.

Experiments being conducted in several schools in the United States represent the gradual introduction into the medical faculty

of representatives of the social sciences. This process started with the employment of social workers to assist in the clinical teaching of the social and community aspects of medicine. More recently sociologists have been appointed to several faculties to develop the application of the social sciences to medical education and research.

As an additional step in integrating the various essential components of medical education, several schools are experimenting with the expansion of their relationships with the community. These efforts are designed to provide a useful teaching and research laboratory in comprehensive medicine and are similar to experiments being conducted in other countries for similar purposes. Dr. Richard Scott (10) has recently described the Edinburgh University general practice teaching unit in which selected medical students are introduced to a "family doctor practice" for some 2,000 patients. The unit comprises two physicians, a public health nurse, a medical social worker, and a pharmacist. Dr. Scott points out that the students seem at first to be preoccupied with clinical matters, then become increasingly interested in the preventive aspects of general practice. During the next step the student talks more freely with the patient and becomes concerned with the physical and economic components of the patient's background.

In addition to their value as additions to the armamentarium of medical education, these developments will undoubtedly improve medical education's understanding of community needs and responses, and they will strengthen channels of communication between clinical medicine and other professional disciplines. This communication is essential to the practice of preventive medicine, and the opportunity for students to observe patients in environments other than the hospital ward should be of the greatest practical value.

Not all medical educators, however, are convinced of the feasibility or even the desirability of expanding the community relations of the medical school. A number of the deans interviewed in a study conducted by the Public Health Service (11) indicated that the costs of providing community services were a major deterrent; others cited problems of personnel

shortages. Some deans even questioned the propriety of extending the influence of medical schools through community services. They feared that such developments would divert the schools' already inadequate resources from the major functions of training and research.

This fear is understandable because of the financial crisis which is facing medical education in the United States. The great advances in medical science make medical education increasingly expensive.

An understanding between the community and the medical school of the role and responsibility of each, however, would allay the fears of medical educators about the burden of community service and would help materially to solve the financial problems of many schools. The high-grade medical service which accompanies clinical teaching constitutes a great benefit to the community, but it is simply a byproduct from the point of view of the medical school. In many parts of our country, it is, nevertheless, still customary to charge the cost of this service, including the full expense of operating a university hospital, to medical education. With this sort of bookkeeping, it is not surprising that a dean should view with concern a suggestion that he add to his costs and dilute the efforts of his already overworked faculty in order to supervise medical students in the community. The community needs to appreciate the service its citizens receive, either in a hospital or elsewhere, and to work out with the medical school a proper allocation of costs and assume its responsibility of paying for the medical service. If this is done, the medical school will have adequate resources to finance what is increasingly recognized as an essential part of its educational program.

Experiments in Community Service

Despite the questions and complexities, however, some medical schools are experimenting with methods to help their students to observe and understand the influence of home and family factors on health. Some of the devices which have been developed are social case studies; preceptorships; assignments of students to general practice clinics or as family advisers; and participation in home care programs.

In addition, several medical schools are assuming broader responsibilities for participating in the development of effective patterns of community health service. Each of these methods increases the student's opportunity for participation in the practice of preventive medicine and helps the medical faculty maintain a high degree of awareness of community structure and health needs.

Social Case Studies

Several medical schools in the United States are actively experimenting with methods of providing closer contact between medical students and the physical and social setting in which their patients live. One striking example is the family adviser service at the University of Pennsylvania Medical School (12). In this program a student, throughout his 4 years of undergraduate training, observes and studies all factors that affect the health of a carefully selected family—housing, food, manner of living, and family relations.

Other medical schools are endeavoring to orient students in the recognition of the importance of social factors of illness by having students conduct medical-social family studies during their supervised clinical experience. These studies are made with the aid of the social service departments of the teaching hospitals and include home visits (13, 14).

Preceptorship

The preceptorship is an adaptation to modern standards of practice and a modern social setup of the old apprenticeship method of training. Some medical schools assign senior students for several weeks or months to preceptorships with general practitioners. At the University of Nebraska, one of several institutions which has adopted this practice, evaluation of the program indicates that it equips the student with a perspective concerning the needs of individual patients and their families, the demands of general practice, and community resources (15, 16). The student has an opportunity to observe the methods used by skilled physicians in serving their patients. He sees patients in their normal home and working environment and observes the way in which physicians draw on public health, welfare, and

other agencies in dealing with the health and related problems of their patients.

The preceptorship system obviously needs careful selection of practitioners who can maintain close relationships with the medical schools in furthering the goals of the plan. The practitioners must, of course, have the time, competence, and type of practice needed to give satisfactory apprenticeship training. There also must be safeguards against the danger that the students will be used for services that have little educational value and thus lose the opportunity for learning the satisfaction of serving patients as people.

General Practice Clinic

Several schools are experimenting with the use of a general practice clinic for instructing students, in place of the exclusive use of specialty clinics. One such experiment is in progress at the University of Tennessee (17) where a large percentage of graduates enter general practice. Family practitioners in the community are on the staff of the "family general practice clinic." They assume primary responsibility for the care of the patient and have available specialists as necessary. The students thus have an opportunity to work with physicians who know at first hand the problems and resources of their community. They also study social and environmental factors in health and illness with the aid of a social worker assigned to the clinic.

A similar program adapted to practice in an urban area is that at the Cornell University School of Medicine (18). In this New York City institution, senior students are assigned for 22½ weeks to a combined clinic in medicine, pediatrics, psychiatry, and preventive medicine. A full-time staff from the departments of medicine and pediatrics forms a nucleus for the organization of this teaching device. The department of preventive medicine focuses all its fourth-year teaching in the clinic. A full-time social worker and a visiting nurse are assigned to the clinic, and part-time specialist consultants are available.

There are many other developments in the direction of expanding community relations of medical schools, but these indicate the trends.

Mentioned earlier were the contributions the social sciences can make in the preparation of physicians for their full role in the practice of preventive medicine. By drawing on the departments of sociology, psychology, anthropology, and economics, for example, some schools are enriching the curricula of premedical and undergraduate medical education. By bringing the social case worker onto the team of physicians, students, and nurses in the experimental programs described, some medical schools are providing valuable learning experience in social diagnosis and therapy.

There are other fields in which the social sciences can be used more extensively and to great advantage in medical schools. In the selection of applicants for admission, for example, medical schools might well draw on the techniques of educational psychology. These techniques are aimed at more precise evaluation of a candidate's personal attributes so as to distinguish those individuals who give promise of success in the study and practice of medicine.

Application of new knowledge in the psychology of learning can aid the medical school in improving its methods of teaching. Recent studies clearly indicate the need for greater use of visual aids in the teaching of "didactic" subjects. Greater understanding of the dynamics of interpersonal relations, moreover, will help in promoting interdepartmental collaboration at the faculty level, both within the medical school and with other colleges of the university.

Finally, there are large fundamental problems in preventive medicine and public health which cannot be solved without the combined efforts of medical research with social and biological research. When a major health problem of a community is being solved by treating the environment—as in enteric infections—many millions of individuals are protected from disease without realizing what has happened.

However, when the preventive measures require individual decision and action, we are faced with fundamental problems of individual and group behavior. This is true in gaining a family's acceptance of immunization or a mother's acceptance of healthful practices in infant and child care. The task is even more

difficult in gaining the cooperation of individuals and families with the physician in his efforts to prevent chronic disease and mental illness and to maintain personal health.

Research into the "how and why" of individual and group behavior is being recognized by many leaders in preventive medicine and public health as essential to professional education and to sound planning of public health programs. Such research involves both the medical and social sciences, and the medical school can be a leader and a partner, through the initiation and support of studies in cooperation with the schools of social science.

Conclusions

The 4 years that the undergraduate student spends at medical school represent, of course, only one phase—though an extremely important one—of a life-time training in preventive medicine. His home environment, his earliest schooling, and his premedical education lay the foundations for his medical career and for his role in family practice, in a clinical specialty, in industrial medicine, in hospitals, in public health, in research, or in teaching future physicians.

Raymond Allen, the physician-president of one of our large universities (19), has expressed a thought with which I would like to close. He says, "Medicine with its age-old concern for the sick, the poor as well as the rich, the weak as well as the strong, has been an influence for good surpassed only by the moral precepts of religion." Medicine of the future, if it is to progress as a social as well as a biological science, must broaden its outlook and adjust its educational program accordingly.

I believe we can all agree that as Dr. Allen states, medicine is coming of age as a social science in the service of society.

Increase in Social Insurance Recipients

As of July 1953, 4.4 million people were receiving old-age and survivors insurance benefits under the Social Security Act, and 2.6 million people over 65 were receiving old-age assistance payments, according to the Social Security Administration, Department of Health, Education, and Welfare.

In 37 States, more old people received these insurance benefits in 1953 than received old-age assistance. This was true of only 22 States in 1951. The States in which old-age assistance recipients still outnumber those receiving social insurance benefits are mainly agricultural and include a number of low-income States.

The major shift during the last 2 years from assistance to insurance as a source of income for the aged is largely the result of 1950 amendments to the Social Security Act which made more of the aged eligible for insurance benefits.

Experiments In the Control Of Schistosomiasis In Brazil

By WILLARD H. WRIGHT, Ph.D., and
CHARLES G. DOBROVOLNY, Ph.D.

Australorbis glabratus

SCHISTOSOMIASIS, a disease caused by three species of human blood flukes, *Schistosoma haematobium*, *S. mansoni*, and *S. japonicum*, is widely distributed in Africa, the Near East, the Orient, the Caribbean area, and parts of South America. It has been estimated (1) that there are 114,400,000 individuals in the world who are infected with the disease. It usually runs a chronic course, and the patient may suffer for years before finally succumbing to the cumulative damage or intercurrent infection. In most endemic areas, natives are

continually exposed to the disease, and repeated infections are the rule.

Schistosomiasis is not an acute fulminating disease with the spectacular manifestations of cholera, yellow fever, or some other bacterial or viral infections. Because of this, the public health importance of schistosomiasis has received little attention until recently. However, now that the success of residual insecticides in malaria control has been demonstrated, health agencies in some countries are encouraged to devote more attention to the possibilities of

Dr. Wright has been chief of the laboratory of tropical diseases, National Institutes of Health, Public Health Service, since 1939 when the laboratory was known as the division of zoology. Dr. Wright was field director of the Army Surgeon General's Commission on Schistosomiasis in the Southwest Pacific and Japan in 1945-46. He has been past president and councilor of the American Society of Parasitologists. He is currently a lecturer in medical zoology at the George Washington University School of Medicine and a visiting lecturer in tropical public health at Harvard University.

Dr. Dobrovolsky, a parasitologist on the staff of the laboratory of tropical diseases, National Microbiological Institute, National Institutes of Health, came to the Public Health Service in 1948 from the University of New Hampshire, where he was chairman of the division of biological sciences. He participated in the laboratory's malaria study in Guatemala in 1948-50 and since 1951 has been at Recife, Brazil, working on the field experiments with molluscicides.

*On the frontispiece of this issue of Public Health Reports are shown all stages in the life cycle of the human blood fluke, *Schistosoma mansoni*.*

controlling schistosomiasis by means of vector elimination.

An Economic Burden

Because of its debilitating nature, schistosomiasis exacts a considerable economic toll in many areas in which it is endemic. In Egypt, it is estimated that the disease costs the country approximately \$57 million a year and lowers the productivity of the population by 33 percent. In Japan, health officials of Fukuoka and Saga prefectures have estimated that the cost of the disease in the endemic area on the island of Kyushu runs to \$2,522,200 a year in wages alone, not counting costs of medical care. Since schistosomiasis is highly endemic in many of the world areas from which the United States draws strategic materials, the disease, along with other tropical infections, represents a substantial tax on imports which this country buys from such areas.

In 1943, the laboratory of tropical diseases of the Public Health Service undertook, at the request of the Surgeon General of the Army, certain studies on schistosomiasis of importance from the standpoint of military preventive medicine. Somewhat later, when it appeared that military personnel might become infected with the disease and serve as focuses for possible establishment of the disease in the continental United States, experiments were undertaken to determine whether any domestic species of snails could serve as intermediate hosts. The effect of water and sewage treatment processes on infectious material was also studied.

Studies on Snail Destruction

The availability of suitable snail hosts in laboratory colonies provided the opportunity for studies on snail destruction as a method of control for the disease. These studies were inaugurated after World War II, and many hundreds of chemical compounds were screened for their effectiveness against *Australorbis glabratus*, the snail which serves as intermediate host of *S. mansoni* in the Caribbean area and certain parts of South America (2). The results of the laboratory tests provided data for a correla-

tion between chemical structure and molluscicidal activity and indicated a number of compounds with sufficient promise for field testing. Initial tests were carried out in Texas (3) against snails closely related to vectors in South America and later against *A. glabratus* in endemic areas of the disease in Puerto Rico (4). Subsequently, in cooperation with the Mutual Security Agency and the British Colonial Office, tests were extended to Nigeria and Sierra Leone by personnel of the laboratory of tropical diseases.

Among the chemicals tested in the field, sodium pentachlorophenate has proved one of the most effective. This chemical is in ready supply commercially and is reasonable in cost. In one test in Puerto Rico, a single application costing \$7 destroyed all *A. glabratus* present in a stream $3\frac{1}{2}$ kilometers long, and the area remained free of infestation for several months. At Tudun Wada, Nigeria, \$3 worth of the chemical eradicated all of the schistosome vectors (*Biomphalaria pfeifferi* and *Physopsis africana*) from a stream 2.2 km. in length, and the stream remained free of these snails for nearly 11 months. At Rigachikun in northern Nigeria, these same species were eradicated and remained absent for 16 months from a stream 4.4 km. in length at a cost of less than a half penny per person of the population in the area.

Technician removes snails from tanks in preparation to test snail-killing efficacy of chemicals. Experiments conducted at the laboratory of tropical diseases, National Institutes of Health, Public Health Service, Bethesda, Md.

No Specific Treatment

The attack on the molluscan intermediate host offers one of the most promising approaches to the control of schistosomiasis. At the present time, there is no specific treatment for the disease, and efforts to effect control through chemotherapy have generally resulted in failure. Sanitary control through the proper disposal of excreta containing the ova of the parasite is complicated in many parts of the world because of religious or agricultural practices. Furthermore, many workers in certain types of agriculture are constantly exposed to infection, thus creating an occupational hazard. For these reasons, it would be difficult to change present practices for the purpose of avoiding infection.

Cooperative Project in Brazil

The preliminary field trials on snail destruction led to an extended study of certain molluscacides under field conditions in Brazil. This cooperative project was begun in February 1951 under the auspices of the Pan American Sanitary Bureau and at the invitation of the Ministry of Education and Health of Brazil. Two scientists from the laboratory of tropical diseases, National Institutes of Health, were detailed to the project, and transportation in the country, technical assistance and equipment, and laboratory space were provided by the Brazilian Ministry of Education and Health.

Headquarters for the project were established at the Instituto Aggeu Magalhães in the seaport city of Recife in the state of Pernambuco, which is in the heart of a highly endemic schistosomiasis region. This region, 7° to 15° south of the equator, extends from a narrow littoral along the Atlantic Coast to a low plateau several hundred miles inland. The plateau is intersected by numerous small rivers along which most of the villages and towns are located. The climate is tropical, humid along the coast, and dry in the semidesert area in the interior. The annual rainfall ranges from about 80 inches along the coast to a few inches on the inland plateau, almost all of it falling in the months from March to September.

The snail intermediate hosts, *A. glabratus*

and species of *Tropicorbis*, inhabit many of the fresh water streams, lakes, and drainage and irrigation ditches in this region. Because sanitary facilities, except in the largest cities, are completely lacking, these waters are used for all washing, bathing, and laundering. Water for cooking and drinking is frequently procured from the same sources.

Field Trials With 33 Chemicals

Thirty-three chemicals which had proved to be 100 percent effective against *A. glabratus* in concentrations of 10 ppm or less in tests conducted in the laboratory of tropical diseases were sent to Brazil for field trials.

Initial field trials with each compound were made in isolated test plots in still water pools or ditches. In some instances, dams were constructed in ditches to isolate control areas from treatment areas. Just before application of the chemical, the volume of water in liters of each test plot was computed from measurements of the length and the mean width and depth.

The highly endemic schistosomiasis regions in the Caribbean area and in South America are shown above in the shaded areas. Note particularly the coastal area of Brazil.

In the first experiments with each compound, the same method of application was employed—a solution or suspension of the chemical dispersed with a compressed air sprayer at a calculated rate of 10 ppm. Later, other methods of application, depending on the composition of the compound, were often employed. Some compounds were mixed with inert materials like talcum and applied with rotary dusters. Compounds in solution were soaked in dry sawdust, which was then dispersed by hand (5). The different methods employed with a given compound were usually about equally effective. Compounds found to be effective applied at 10 ppm were then tried in lower concentrations.

The pretreatment snail survey of each test plot was made shortly before the chemical was applied. Posttreatment surveys to determine the effects of the compounds on snails were made weekly or more frequently. The effectiveness of the chemical in each survey of each experiment was expressed in the percentage reduction in the snail population. The effectiveness at 10 ppm of 33 compounds in preliminary field trials in static waters was determined over a 6-week period following application. The results beyond 6 weeks of observation are not directly comparable because some test plots dried up.

The effectiveness of 8 of the 33 compounds tested was 90 percent or less. With 18 compounds, results of various trials showed complete kill of snails in some instances but only 90 percent reduction in snail population in others. The remaining 7 compounds found to be 99 to 100 percent effective against the snails in all tests were: pentabromophenol; pentachlorophenol (Hercules special emulsion); copper pentachlorophenate; sodium pentachlorophenate; bis(3,5,6-trichloro-2-hydroxyphenyl) methane; sodium salt of bis(3,5,6-trichloro-2-hydroxyphenyl) methane; and phenyl mercuric acetate. Most of the above compounds were also 95 to 100 percent effective when applied at a concentration of 2 ppm.

Value of Sodium Pentachlorophenate

Since many of the flowing streams in the highly endemic schistosomiasis region of Brazil are infested with snails, it is essential that mol-

Workers collect snails from one of the snail-infested streams in the state of Pernambuco, Brazil.

luscicides be effective in flowing water. Of the chemicals tested in streams, sodium pentachlorophenate proved to be the most effective. Because this chemical is not very toxic to mammals in the concentrations employed, it was used in extensive field trials in flowing waters.

In these experiments, the compound was usually applied at the head of the stream and in some instances at selected intervals along the stream. The amount of chemical to be applied was calculated from the rate of flow for a given number of hours at selected levels downstream. In most streams, the rate of flow was determined with the aid of a pigmy current meter or by construction of a weir. Different methods of application employed gave satisfactory results. Observations were also made on the rate and extent of dispersion of the compound in streams from samples of water (6) taken at various points below the sites of application. It was found that the disappearance of chemical from the water below the site of application in the stream was usually greater than expected on the basis of calculation. In most of the streams, the rate of disappearance was so rapid that little chemical was carried downstream more than 4,000 feet.

As might be expected from the above observations, the kill of snails was least successful in the lower parts of the stream. In most of the streams, the chemical was most effective in the area down to 1,000 feet below the site

of application, indicating the intervals at which application should be made. It was also found that sodium pentachlorophenate is usually most effective when applied at concentrations of at least 10 ppm. On the other hand, concentrations exceeding 20 ppm applied for 8 hours or more did not enhance the molluscicidal effects of the compound. The effectiveness is a function of time of application as well as of concentration. Thus concentrations as low as 2 ppm maintained for 40 hours were about as effective as high concentrations for 8 hours.

Effective Snail Abatement

A marked reduction—frequently 100 percent—of snail populations in streams was observed following a single application of sodium pentachlorophenate. No living snails were found in 11 of 28 streams during the first month after treatment, and in parts of some streams no living snails were discovered over a 12-month period. However, most of the waters from which the snails appeared to have been eradicated were repopulated by the fourth month after treatment. The sudden appearance of mature and large specimens in snail-free waters indicated that reinfestation was accomplished by snails which were not in the water at the time the chemical was applied. These streams appeared to have become reinfested in a number of ways. In moist, shady habitats, snails often migrate to the wet banks, and following treatment may return to the streams. Snails left stranded on the banks of streams following high waters and snails raked on the banks with vegetation when streams are cleaned go into estivation. During rains they may migrate or be washed back into the snail-free waters.

Since a single application usually produced effective control for about 3 months, various field trials were made to determine the effects of repeated applications of sodium pentachlorophenate at different levels of the stream and at selected intervals of time. In most of the sur-

veys made in these streams for periods up to 12 months, the reduction in the snail population was 95 to 100 percent, based on the first pretreatment snail counts. Results with the experiments conducted to date illustrate that effective snail abatement can be attained by treatments at intervals of 3 or 4 months. However, because of the ability of snails to survive in some of the ways mentioned, eradication of snails cannot be accomplished in 1 year.

In view of the different conditions under which sodium pentachlorophenate was applied, variable results were to be expected. Compared with the results reported elsewhere, there are indications that the technique of application of molluscicides may require considerable variation from one geographic area to another, depending on the ecologic conditions of the snails. In the main, the results obtained in Brazil have served to clarify some of the problems encountered in snail control and to suggest the need and direction for further experiments in the solution of these problems.

Sanitation Problems in a Suburban Area

—Jackson County, Missouri—

By JACK K. SMITH, M.S.C.E.

JACKSON COUNTY, MO., is not a typical county. It may best be described as an urban-fringe area, or a girdle of homes, and schools, and shopping centers, of small industries, and small farms, and wide open spaces, which typically encircles a major city in the United States. Many of the workers in Kansas City, Mo., which lies within Jackson County's borders but not within its jurisdiction, have their homes in the residential communities which surround the city. With the growth and expansion of Kansas City, the problems of providing healthful living conditions for residents of the county become more and more complex. Sometimes these problems are not sufficiently known and are taken for granted.

Recently, the necessity for explaining the objectives of specific public health programs was brought forcefully to the attention of the Jackson County Health Department. Although the department had been in operation for more than 20 years, the Jackson County Court indi-

cated, when questioning the local unit about its purpose and activities, that in the thinking of the court, the activities of the health department centered around only one phase of health—the medical care of the indigent.

This lack of understanding on the part of the court, and undoubtedly on the part of the public, becomes all the more pertinent when one realizes that the Jackson County Court is not a part of the Missouri judicial system and that the term "court" is a misnomer—a vestige of the days when the judicial and administrative powers were combined in one local governmental unit. Apparently, the health department had temporarily failed in keeping the public, and likewise the court, continually informed about its purpose and its programs. It had failed, moreover, in explaining that its primary purpose is the prevention of sickness and that its activities were directed toward that end.

Community enlightenment is, of course, an essential ingredient of a health department's program. In Jackson County, as in other localities in the United States, the real purpose of a local sanitation program is improvement of the sanitary environment. But progress in any community program, let alone a health program, can be made only to the extent and at the pace desired by the residents of the community. No matter what value is placed on a local program by the professional health worker, the program, if it is to succeed, must have the support and understanding of the community.

Mr. Smith is in charge of waste disposal and stream sanitation in the bureau of public health engineering, Division of Health, Missouri Department of Public Health and Welfare. From October 1938 to May 1952 he was a public health engineer in the health departments of Jackson County and Jasper County, Mo. This paper is based on a presentation by Mr. Smith before the Illinois Public Health Association at its 1952 annual meeting in Springfield, Ill.

Some of the local sanitation programs in Jackson County have already benefited by public recognition of the need for their existence.

Milk Control Program

Jackson County's milk control program was inaugurated in 1940. It started slowly at first with an attempt to get the cooperation of the milk producers and dairies. A few, however, would not go along. One merchant in the vicinity of Kansas City made a "leader" of milk, which he obtained from any source and sold at a reduced price. County health officials explained to him that the milk control program was intended to assure a safe milk supply for the county, and told him to buy milk only from a rated source. The merchant, taking the attitude that the health department did not have the right to interfere, continued to sell ungraded milk.

At this point in the program, the health department decided to use enforcement as a means of education. Evidence of the merchant's selling ungraded milk was collected by the health department and presented to the magistrate's court, the lowest court in the county. The magistrate ruled in favor of the health department, and the merchant was fined. This was the only legal case involving the sale of milk which was ever tried in Jackson County.

The problem of milk control in the county area is diminishing because the large dairies in nearby Kansas City, Mo., are gradually taking over the distribution of milk. In 1940, there were about 50 small dairies in the county; most of these were raw milk dairies. Today, there are only 4 or 5 small dairies.

Because of overlapping milksheds, reciprocity in providing a safe milk supply was established with the Kansas City Health Department. The Kansas City Health Department now inspects all dairies selling milk within the limits of Kansas City; and milk plants licensed by the city health department are issued a permit by the county department. When Kansas City degrades a dairy, the county health department takes similar action. However, the few small pasteurization plants that are left—dairies that produce and pasteurize milk on the

farm—are under the supervision of the county department.

The cooperative inspection program between the city and the county extends beyond the city limits. Across the State line from Kansas City, Mo., is Kansas City, Kans., with a number of large dairies which have recently started to distribute milk in Missouri. Since these dairies are inspected and certified by the Kansas State Board of Health, the Jackson County Health Department decided to avoid duplication of inspection by accepting Kansas' certification. The Public Health Service through its regional office at Kansas City, Mo., provided a milk sanitation rating of the Kansas dairies desiring to sell milk in Missouri. Only dairies with a rating of 90 percent or higher were issued permits. It was mutually agreed that degrading by one State would call for similar action by the other. This agreement has been beneficial to both States.

In Jackson County, the disposal of the waste connected with milk production is a problem. Outside the limits of Kansas City, there are few public sewers. Dairies do not have access to these sewer systems. One large milk plant utilizes a high-rate trickling filter for the treatment of wastes, but results have not been satisfactory because of overloading and inadequate maintenance and operation. The small milk plants have no facilities for treating wastes. A simple, efficient, and inexpensive type of waste disposal system is greatly needed.

County Water Supplies

Water supply in Jackson County is primarily supplied by the municipal water plant in Kansas City, Mo., which serves the city and surrounding area through public water supply districts. There are eight such districts in Jackson County. Each district has its own board of directors. Each district has the power to vote bonds and extend the mains within its area. Water purchased from Kansas City is resold by the public water district. Thus, the municipal water plant serves about 95 percent of the population of the entire area. By this arrangement, the people of Jackson County have access to a water supply managed and operated by qualified technical personnel. Bac-

teriological samples from the eight districts are examined routinely by the Missouri Division of Health laboratories.

It would be difficult to develop individual water supplies in the county. There is no suitable underground supply except in the Missouri River bottoms, where ample water is found at a depth of 20 feet. The Missouri River forms the northern boundary of Jackson County. Sand-point-driven wells produce satisfactory water from a bacteriological standpoint. Away from the Missouri River, wells are seldom satisfactory. There are a few low-producing drilled wells, but a good drilled well is rare in the northern part of Missouri.

The water supply problem in the county is increased because the area is largely underlaid with creviced limestone, which permits little filtering action. Contamination from barnyards, septic tanks, privies, and other sources, enters the water stream through outcropping limestone ledges. Cisterns are used at many private homes and small public schools. Most of the water for these is hauled from one of the water districts. Water haulers are instructed to chlorinate each tank of water they transport. For one school with about 200 students every drop of water must be hauled. The school is otherwise completely modern, with flush toilets and a cafeteria. Several thousand dollars have been spent in unsuccessful drilling for wells. There simply is no water available in the ground.

Sewage Waste Disposal

The waste disposal problem resulting from the numerous housing developments in Jackson County presents a significant challenge to the county department. In April 1951, the Missouri Division of Health adopted a regulation for septic tank installations which requires a minimum lot area of 15,000 square feet with a minimum lot width of 75 feet, although 100 feet is preferred. This has helped to reduce the septic tank problem. The developer wishing to erect 50 or more houses is advised that he may use a lot size of 7,500 square feet if he installs a sanitary sewer system and a disposal plant. Several builders have done so. After completion, the disposal plants are maintained

and operated by the county sewer department.

A county of the first class can levy a maintenance tax for sewered areas and provide satisfactory maintenance. Counties are limited by law to one-fourth of 1 percent of the assessed valuation as the maximum that can be charged for operation and maintenance of a sewer system. A development needs at least 50 houses in order to bring in enough revenue to operate even the simplest type of disposal system.

In a subdivision of 50 to 75 houses the simplest type of sewage disposal system is a large septic tank, dosing chamber, and open sand filter. When given proper maintenance, the sand filters work very well. A sand filter requires continual maintenance and cleaning, but it produces a satisfactory effluent. Expensive to operate, the sand filter is a partial solution to the sewage problem because the disposal system is then centered at one point rather than dispersed among separate lots and individual owners.

The arrangement for the county to assume control of the sewage disposal system has worked out satisfactorily. Sometimes complaints are made that the revenue is not enough to take care of the expense, but this can be overcome largely by efficient operation. Personnel from the county health department make routine inspections of the disposal plant and report the deficiencies they find to the county sewer department.

Other Disposal Systems

There are other types of sewage disposal plants. In a development of 550 houses, a primary settling tank, separate sludge digester, trickling filter, and final settling tank have been installed to accommodate 275 houses. The system will be expanded to accommodate the ultimate capacity of 550 houses. The developer will operate the system until its completion and then deed it to the county.

The big problem, of course, is inducing the developer to put out that much money at one time. The cost, when the price of land is considered, usually will justify a community disposal system, and an appeal to the developer's pride has resulted in having some builders provide a sanitary sewer system.

Individual septic tank installations produce

many problems. The type of soil in Jackson County is not readily adaptable for the installation of soil absorption systems. A percolation rate of 10 minutes per inch is very good, but in almost all subdivision lots the percolation rate is the maximum permitted by the county, 30 minutes per inch. When the percolation rate exceeds the maximum, the builder is instructed to use some other type of system such as a sewer collection system with central treatment works or an installation of individual sand filters on each lot.

The individual sand filter creates problems too because the effluent from each filter must be carried away. In some instances a small sewer system is required. The cost of the individual filter installation exclusive of effluent drain is approximately \$150 more than that of the conventional absorption system. Numerous individual sand filters have been installed in spite of additional cost and effluent drainage problems. Builders and developers sometimes request permission to build 1 large filter to serve 5 or 6 houses, but this permission is not granted because it involves too large a maintenance problem.

However, the use of a common collection tile or sewer is permitted. It involves a minimum amount of maintenance. As yet no difficulties have been encountered with this type of drain, although some of the installations were made 5 years ago.

Jackson County has a readily available source of sand for use in sewage filters, but care in selecting the type of sand used is necessary. An effective size of from 0.6 to 0.8 millimeters, with a uniformity coefficient of less than 4, is required. Considerable labor is involved in producing sewage-filter sand. Ordinary building sand will give good results, but only for a short time because of its tendency to clog.

School Sanitation Progress

In a sprawling suburban area, the construction of schools lags behind the expanding population. Jackson County schools are overcrowded and probably will be so for some time. However, school districts are being consolidated. Gradually being eliminated are the small, one-room schoolhouses with their prob-

lems of cross-lighting, inadequate water, inadequate sewage disposal facilities, and other conditions not compatible with good health. School architects in the county have been cooperative in submitting school building plans and specifications to the health department. In reviewing the plans, the department checks the lighting, ventilation, drinking fountains, toilet facilities, accident and fire hazards, food service facilities, and water supply and sewage disposal facilities.

Schools with an enrollment of 200 to 300 students have difficult sewage disposal problems. Because most small towns lack public sewerage systems, the school has to develop its own sewage treatment plant. Usually, the installation consists of a septic tank, a dosing chamber, and an open sand filter. One public school has an absorption system with more than 5,000 linear feet of tile. Wherever possible, an open sand filter is used. With proper maintenance, very satisfactory results are obtained.

The high cost of school buildings has one advantage from the health department's viewpoint: New schools are being constructed without basements. It has been difficult to convince architects and school boards that a cafeteria or kitchen should not be placed in the basement. Newer schools now have well-lighted and well-ventilated cafeterias above-ground.

The importance of checking the complete set of school plans has been borne out by experience. Recently, an architect supplied for review only the plans of the sewage disposal system, which he thought were the only ones needed. The plans were satisfactory and provided for an absorption system of adequate capacity with a tile field in excess of 5,000 feet. However, when final inspection of the disposal system was made, it was found that the laterals were laid on top of a foundation drain. The submitted plans had not shown the foundation tile, but the complete set did. When the disposal system was constructed, the laterals were placed only a few inches above the foundation drain. As soon as the siphon discharged, the sewage seeped into the lower drain and then into the street. The contractor had to re-lay the foundation drain, removing it from beneath the laterals.

Nursing Home Inspection

In order to obtain a permit or license to operate a nursing home in Jackson County, certain minimum requirements must be met. The State legislature enacted a law regulating nursing homes in 1941. Inspection of nursing homes is the responsibility of the county health department and requires the services of the health officer, the sanitary engineer, and the public health nurse. The nursing home program includes investigation of the sanitation of the premises; patient care and treatment; record-keeping; fire, electrical, and physical hazards; food-handling practices; sources of milk and food; water supply; and sewage disposal.

One legal case involved a nursing home which was well operated and maintained but whose owners believed that they were not subject to the health department regulations. The home was not violating any sanitation regulations, but it refused to submit monthly reports, and also disapproved of health department inspection. In the ensuing litigation, the circuit court judge ruled that the State nursing home law was unconstitutional because it excluded homes healing by faith. However, the decision applies only to this home in Jackson County.

The failure of certain nursing homes to meet minimum requirements necessitated other court cases. The procedure in such instances is to inspect the home, interpret the findings to the operator, and allow sufficient time to make necessary adjustments to fulfill the requirements for licensing. At the end of this period, the home is reinspected; and then, if the recommendations have not been carried out, and there is no intention of following them, the case goes to the county prosecuting attorney.

The prosecutor writes to the nursing home operator, calling for a hearing at which the operator and a representative of the health department are present. The points in question are discussed. The prosecutor advises the operator to meet the requirements of the law. A reasonable time is given for compliance. If, at the end of that time, the operator has not complied, a warrant is issued for his arrest. Usually, the hearing concludes the matter.

The health department, of course, tries to

avoid hearings, principally because of the amount of time they take.

Taxing Trailer Residents

Along with other States, Missouri has sanitation problems peculiar to the people living in trailers. Trailer parks have presented a serious sanitation problem during World War II. The number of trailers has increased since the war. People are continuing to live in trailers. Their income frequently is high, and they choose to live in trailers not for economic reasons, but because they like it.

Almost all the sanitation problems common to a small city are found in a trailer park. Water supply, sewage disposal, garbage, and refuse disposal are the major items requiring supervision by the health department. Fortunately, all trailer parks in Jackson County are served by an approved public water supply. Where trailer parks are not served by public sewer systems, the trailer park sewerage systems consist of collection systems, septic tanks, dosing chambers, and open sand filters. In the county, there are 15 trailer parks varying in size from a 10- to 100-unit capacity. A water supply connection and a sewer connection must be provided for every trailer space.

In most instances, the older trailer parks were not properly planned, and little consideration was given to the location of waste disposal facilities. As a result of this lack of planning, there is insufficient area for waste disposal facilities and a need for pumping sewage. Odor problems are common because of the proximity of trailer spaces to the sewage filter beds. Use of chemical masking agents in sewage dosing chambers has provided some relief.

A large percentage of new trailers are equipped with showers, lavatories, kitchen sinks, and flush toilets. These improvements require sanitary sewer and water supply connections for the trailers. The central bathhouse of the typical park is rapidly disappearing. Centralized laundry facilities are, of course, still necessary. Laundry waste is treated with other sanitary sewage and has created no special problems.

Garbage and refuse collection and sewage disposal practices vary from good to bad. Ex-

perience indicates that the most satisfactory system is to provide a fly-tight metal container for each trailer unit and to accomplish disposal either by sanitary landfill or by incineration at a remote location. Most of the owner-made incinerators have not been successful. Central refuse containers require almost constant supervision to avoid abuse of the facilities.

The inherent problems of the older trailer parks created by the small unit spaces are being alleviated by the need for accommodating the new, larger trailers and the development of trailer park standards by the National Association of Trailer Coach Manufacturers.

Real estate interests and school authorities in the county strongly object to trailer parks. School authorities object because little, if any, tax revenue is obtained from the trailer occupants. A small school, or even a fairly large one, with a park of 150 trailers within its district, faces the problem of educating 50 to 75 extra pupils without adequate funds for additional space, equipment, or teaching personnel. The school board and others protest to the zoning board against a proposed trailer park and usually find a sympathetic audience.

Probably trailer park residents would not object to being taxed, but there is now no legal way in Missouri to tax them. The trailer coach manufacturers have asked the legislature for legislation to tax trailers for school purposes, but so far the State has adopted none. This problem will continue to exist until some form of legislation permits taxation of trailer occupants. (Note: The 1953 legislature passed legislation permitting counties to tax trailers for school purposes.)

The real estate interests have stated that trailer parks lower real estate values in their vicinity. But we believe that there should be a place in any county or community for well-

organized, sanitary trailer parks. Zoning authorities should select areas for such purposes so that there will be better trailer parks, rather than those which have just grown up from 2 or 3 trailers, adding to their original facilities in a hodgepodge fashion. Parks which are built according to a definite plan can be assets to the community. Health departments must face their obvious responsibilities toward the people who live in mobile homes.

Nuisance Adjustments

Many nuisance complaints can be adjusted during a careful interview with the complainant. Some complaints turn out to be purely personal grudges. Sometimes they are disagreements about a property line or a fence, and the health department is used as a moderator.

The first question asked the complainant is "Have you talked to your neighbor about this insanitary situation?" Generally, the answer is "No." The representative of the health department then tries to persuade the complainant to speak to the neighbor and remind him that otherwise he must sign a written complaint and perhaps testify in court.

This procedure stops many complaints before it becomes necessary even to write a letter. When a condition cannot be remedied peacefully, an inspector checks the sanitation facilities of both parties. When conditions warrant, the owner receives a letter asking him to make certain corrections and giving him a reasonable amount of time in which to do so. If the corrections are not made within that time, a hearing before the county prosecutor is requested. If the hearing fails to bring results, the case is taken to court. Actually, not many cases reach that stage.

Coxsackie Virus Antibody and Incidence of Minor Illness During the Summer

By MARY WALTON, M.D., Dr.P.H., and JOSEPH L. MELNICK, Ph.D.

THE ROLE of Coxsackie viruses in human illness is not fully understood. The existence of 16 antigenic types of these agents with varying pathogenic potential for the mouse has suggested to some that we may actually be dealing with an assembly of agents loosely grouped together rather than with members of a single family (1-5). These agents have been isolated from patients with a variety of illnesses, and evidence has been presented for identifying certain members, for example, types A2 (Fleetwood) and A4 (Texas-1), as the etiological agents of herpangina (6) and others, for example, B1 (Conn.-5) and B3 (Nancy) as those of pleurodynia (epidemic myalgia, Bornholm disease) (7, 8). Although many of these agents have been isolated

from patients simultaneously infected with poliomyelitis virus, or from flies also carrying poliomyelitis virus, the role of the Coxsackie viruses in the etiology of the disease entity known as poliomyelitis remains obscure (1, 2, 3, 9, 10). The present study was undertaken to gain further information on this group of viruses and their possible relationship to minor illnesses of poorly defined nature which are commonly seen during the summer months.

The observations presented were made as a part of the study of poliomyelitis which is being conducted in Charleston, W. Va.

Laboratory studies of the development of poliomyelitis antibodies and measurement of the incidence of acute unclassified infectious illness have been undertaken in an attempt to define more accurately the epidemiology of poliomyelitis, the pattern of which is confused by the high ratio of mild or inapparent to apparent infections. The prevalence of the Coxsackie viruses and the confusion resulting from their epidemiological similarity to the poliomyelitis viruses led us to attempt to describe the incidence of infections with these agents and to investigate the association with the incidence of summer illness in children. The events which occurred during the summer of 1951 in Charleston are described.

The Study Areas

Relatively homogeneous population groups selected on the basis of certain characteristics of environment and socioeconomic status have

Dr. Walton, a commissioned officer of the Public Health Service, is chief of poliomyelitis investigations unit, epidemiology branch, Communicable Disease Center, Atlanta, Ga. Before coming to the Public Health Service in 1947, Dr. Walton served as a health officer, Alabama State Department of Health, and as a practicing physician since 1931. Dr. Melnick, associate professor of microbiology, Yale University School of Medicine, is a member of the panel on virology and immunology, Committee on Growth, National Research Council.

This study and the accompanying one by Dr. Melnick, Dr. Walton, and Dr. Ira L. Myers (p. 1178) were aided by a grant from the National Foundation for Infantile Paralysis.

been under continuous observation since the spring of 1950. District I in Charleston is composed of approximately 900 persons in 200 households in the north central part of the city (fig. 1). In general, the environmental sanitation is poor. The area is not provided with sanitary sewers. The common method of disposal of human excrement is the insanitary privy. A small stream runs through the area receiving surface waste from overloaded cess-pools and septic tanks and wash from the privies. The fly-breeding potential is high. Economic status is generally low. Families are rather large, averaging 4.5 persons. Housing is substandard and crowded. There appears to be ready opportunity for spread of infectious agents by either ano-oral or respiratory routes. District IV is composed of about 1,300 persons in 420 families of middle to upper-middle socioeconomic status living in the southeastern part of the city. Environmental hygiene is standard. The fly-breeding potential is low. Average family size is 3.2 persons. Housing is adequate and not crowded. Personal hygiene practices are generally good.

Methods

Incidence of acute minor illness has been measured since the spring of 1950. Morbidity data are obtained from an adult informant in each household by trained lay interviewers at 4-week intervals. Informants are questioned as to the presence or absence in each member of the household of specific symptoms beginning in the 4 weeks preceding interview. Symptoms, duration, family diagnosis, and a measure of severity are recorded. Severity is measured by the amount of interference with usual activity and is classified as "no reduced activity," "reduced activity," and "in bed." A variable but always substantial portion of illnesses reported falls into the first category. Minor illnesses in the first two groups rarely come to the attention of physicians or health agencies, and thus would not be recorded by any of the usual reporting mechanisms. Incidence rates are, therefore, not comparable with rates obtained through ordinary channels. The schedule of enumeration is arranged so that comparable samples of each population are interviewed each week. The enumerators are regularly rotated

Figure 1. Location of the study areas.

to avoid bias which may result from differences between interviewers.

Laboratory data consist of measurements of complement-fixing (C-F) antibodies to each of four antigenically distinct Cocksackie viruses in paired serums collected in May and November of 1951 from the population under observation in the two districts. The method used for demonstrating antibody has been described (12). A "positive" serum is one reacting at a dilution of 1:4 or greater. A "negative" serum is one which fails to react at a dilution of 1:4. Antibodies to the following virus types were studied: B1 (Connecticut-5), B3 (Nancy), A4 (Texas-1), and A2 (Fleetwood). The classification of Cocksackie viruses has been discussed recently with a comparison of nomenclature used by Dalldorf (3), Huebner (4), and by one of us (5). A rise in C-F antibody is regarded as evidence of relatively recent infection with a Cocksackie virus (12, 13, 16). Even though there are at least 16 immunologically distinct Cocksackie viruses (5), there is evidence of crossing between them in the complement fixation reaction, so that in individual cases antibody rises to types other than the one isolated have been demonstrated (12, 13). The average time of persistence of detectable levels of C-F antibody after infection is not certain but it is known to be variable. It may persist for a year or more; on the other hand it is possible that sometimes it may be of such short duration that a rise could have occurred in some of these individuals and could have disappeared between the spring and fall bleedings (12, 13, 16).

Grab samples of sewage were collected to provide an index of Cocksackie virus infection in the community. Samples were obtained regu-

larly every 2 weeks during the winter months, and weekly, beginning in May, from lines serving the population of district IV and other residential areas in Charleston and two adjacent towns in the metropolitan area. Weekly privy samples were collected in district I beginning in May. The sewage specimens from each area were run in two pools per month. Privy specimens were run in two pools per month from each of four sections of district I. A description of the methods of collection and of testing these samples will be presented elsewhere.

Results

Table 1 and figure 2 show the prevalence of C-F antibody to the four types of Coxsackie virus in the spring and fall of 1951 in the populations in the two study districts. Only paired

specimens are included. Curves are a result of both conversion and reversion between spring and fall. Many individuals developed antibody to more than one type (table 2). It will be noted that in both districts the prevalence of C-F antibody to three types of virus rose during the summer while antibody to the fourth type, Nancy, was less prevalent in the fall than in the spring. No person developed antibody to Nancy alone. The age pattern for each type was different, both in spring prevalence and in change in prevalence between spring and fall.

Table 3 shows rates of conversion from negative to positive during the summer for each type. In both districts, the rate was highest for the Connecticut-5 type. The rate of development of antibody to both Connecticut-5 and type A2 was substantially higher in district I than in district IV. If conversion rate is an

Figure 2. Age distribution of C-F antibodies to four Cocksackie viruses.

indication of extent of spread, then during the summer of 1951 Cocksackie virus spread much more extensively in district I than in district IV. Similar observations have been reported on development of C-F antibodies to the Texas-1 type virus in an urban population during the summer months and its relationship to socioeconomic status and environment (14).

The association between the development of C-F antibody, or conversion, and reported morbidity in individuals and households was investigated. In district I the conversion rate was so high that it is not possible to observe any association between morbidity and indication of the presence of infection with one or more types of Cocksackie virus during the summer period. There were only three households in which no pair of serums became positive to one of the Cocksackie viruses. Households with no conversion in Cocksackie virus antibody had no member with a negative complement fixation to Connecticut-5 in the spring. Only 1 child under 10 years of age had no C-F antibody in the spring or fall to any of the 4 types.

In district IV, the presence of households in which no individual tested developed antibody

permits a comparison of minor morbidity between individuals and groups who did and did not show a rise in C-F antibody to one or more of the types of Coxsackie virus tested during that season. Households in which paired serums showed rises to type 2 poliomyelitis virus

have been excluded. Since infection with a Coxsackie virus spreads in households (1, 2, 6, 10, 11, 15), the association between evidence of infection in households and incidence of illness was investigated. Table 4 shows the total incidence by month of onset of acute minor illness in children under 10 years of age in households in which one or more persons, including at least one child under 10, developed antibody to one or more of three types of Coxsackie virus compared with the morbidity reported in children in households in which serum pairs were tested for children under 10 and no development of antibody was demonstrated. Only unclassified acute minor illness has been included. The common acute communicable diseases of childhood, chickenpox, measles, and mumps, and such conditions as summer sores, impetigo, poison ivy, pinkeye, reactions to immunizations, accidents, and injuries have been excluded. The peak of summer morbidity was in August. Rates in July and September were slightly higher than those in May and June. Incidence of total minor morbidity was also high in October in children in converter households. August incidence appeared to be slightly higher in converter households but differences between the two groups were not notable.

Table 5 shows the symptoms reported in the children with an unclassified acute minor ill-

¹ Children who showed rises in C-F antibody to type 2 poliomyelitis virus have been excluded from both groups.

ness during the peak month of August. The symptoms listed are those regarding which specific questions were asked. Other symptoms included earache, upset stomach, and additional respiratory symptoms. There was no report of chest or pleuritic pain. A significant excess of fever was reported by children in households with conversions. Sore throat and vomiting were also present in some excess in this group. In one block in district IV, not included in the spring serum collection, type A2 Cocksackie virus was isolated in July from each of six children tested during a study of a localized excess of acute minor illness. Five of the six tested plus one household contact reported sore throat and fever. This experience is described in the accompanying report.

A summary of acute minor illnesses reported in individual children who developed antibody is shown in table 6. The children have been separated into two age groups, and illnesses are listed by type of Cocksackie virus to which C-F antibody developed. Five children, 1 to 3 years of age, developed antibody to Texas-1 only. All reported febrile illness during the interval between bleedings, 2 in July, 2 in August, and 1 in October. All were too sick for normal ac-

tivity and 3 were in bed. Two reported sore throat, 1 vomiting, and 1, the 3-year-old, complained of headache. Six children, 5 to 12 years of age, developed antibody to type A2 only. In this group no fever or sore throat was reported. Three had attacks of vomiting in October. Among the individual children 1 through 5 years of age showing a rise in C-F antibody to the Connecticut-5 virus, 7 out of 9 had a febrile illness in August or September, 4 had sore throat, 4 reported vomiting, and 3 headache. Classified by severity, one of the illnesses caused no reduction in the child's activity, two produced reduced activity, and 5 of the children were in bed. Of 8 children 6 to 14 years of age showing a rise in antibody to the Connecticut-5 virus, 1 reported sore throat and another reported fever. It is interesting to note that 13 of the 14 children of ages 1 through 5 had fever, sore throat, or both; only 1 of the 14 in the older group reported fever and 1 complained of sore throat.

Table 7 shows the number of illnesses in the children in each group of households in which fever or sore throat was reported as symptoms. There were 22 such illnesses in the children in households with conversions (average popula-

Table 7. Incidence in 1951 of unclassified acute minor illness with fever or sore throat in children under 10

Month	Households with conversions			Households without conversions		
	Number	Cases	Rate (per-cent)	Number	Cases	Rate (per-cent)
May.....	42	2	5	39	5	13
June.....	41	2	5	36	0	0
July.....	36	4	11	30	2	7
August.....	38	14	37	32	2	6
September.....	43	8	19	39	1	3
October.....	43	7	16	38	2	5

tion, 41) in August and September while among those in households with no conversions (average weekly population, 35) only 3 were noted. The rates for May, June, and July are similar in the two groups. In October, the difference is within chance range. The weekly incidence of illness with sore throat or fever in each group of children is shown in figure 3. Such illnesses in the children in households with antibody rise appear to be concentrated in the latter part of August (calendar weeks 33-35). There is also a little concentration in weeks 28-31, the period during which the block outbreak described in the accompanying paper occurred. As also shown in figure 3, Coxsackie virus was isolated from the sewage from District IV in the latter part of July and again in the first half of September. Pools of August collections were negative. Sewage from other areas in the community was positive intermittently from the first half of July until mid-October.

The average population under 10 years of age in district IV was about 380 during July and August. The total incidence of acute minor illness reported during this midsummer period, excluding accidents and injuries, was 28 per 100 in July and 37 per 100 in August. About 6 cases per 100 in each month were identified as mumps, impetigo, pinkeye, or other miscellaneous entities. The remainder fell into an unclassified group. The monthly

incidence of total unidentified illness and of those illnesses in which fever or sore throat was reported are shown in tables 8 and 9, compared with reported morbidity in the children in "conversion" and "no conversion" households. Rates for July are similar for the three groups. In August the children in households in which one or more developed C-F antibody reported a higher incidence of unclassified acute minor morbidity than did the whole population, especially of illnesses with fever or sore throat. These children, about 10 percent of the total population, accounted for nearly 25 percent of the total fever and sore throat incidence.

Discussion

The development of the C-F test for detection of antibody to the Coxsackie viruses has made available a tool which can be used to measure infection with these viruses in population groups. The test has the advantage of being relatively inexpensive, so that large scale observations are feasible. It lacks type specificity, however, to the point that in individual cases the type of the infecting virus cannot be determined. In spite of this limitation, the use of this technique may be of value in indicating broad epidemiological patterns of infection with this group of viruses. Combined with limited use of more specific but costlier methods of virus isolation and typing and studies of neutralizing antibody, it may permit adequate studies of the epidemiological and clinical characteristics of infection. The data presented here indicate both the usefulness and the limitations of the method.

Index of Incidence of Infection

The prevalence of Coxsackie C-F antibody in population groups should be an index of the incidence of infection during the period of average persistence of the antibody (14). The observations show that Coxsackie infection was common in Charleston prior to the first serum collection. In each district over 70 percent of persons tested had C-F antibody in the spring to one or more of the four types studied (table 2). The prevalence of antibody was not sig-

Figure 3. Weekly incidence of illness with sore throat and/or fever in households, and seasonal distribution of Coxsackie viruses in the area.

nificantly different in age groups over 4 years in either district or between the two population groups. Children 4 years of age or under in district I, the insanitary area, had C-F antibody to one or more of the viruses in somewhat higher prevalence (55 percent) than those in district IV (28 percent), an area with standard environmental hygiene. Prevalence of antibody tended to increase with age to about 14 years, after which the level remained essentially the same. It appears that infection was still taking place in the adult population. Since the average time of persistence of C-F antibody after infection is not known, and the picture is complicated by heterotypic responses, yearly incidence rates cannot be estimated. Even if detectable antibody persists longer than a year, incidence of infections with this group of agents must have been high at all ages.

Incidence of infection with a Coxsackie virus during the summer of 1951 was estimated by

study of C-F antibody to four types of virus in paired serums collected in May and November. Conversion from negative to positive is considered to be evidence of infection occurring in the interval between serum collections. Sixty-seven percent of children under 10 years of age in district I and 36 percent of children of the same age in district IV developed C-F antibody to one or more of the types studied. Conversion rates in persons age 10 and older was 25 percent in both district I and district IV. In children under 10 in district IV, 22 (73 percent) of 30 conversions were to a single type; 6 children developed antibody to 2 types and 2 children to 3 types. In district I only 9 (28 percent) of 32 conversions were to 1 type. Twelve children (38 percent) developed antibodies to 2 types, 10 to 3 types, and 1 to all 4 types. It is known that in response to infection with a 1 type of Coxsackie virus, rises in C-F antibody may occur not only to the infecting

type but also to heterologous types (12, 13, 16). The mechanism responsible for rise in heterologous antibody is not known, but it has been suggested that it may be an indication of previous infection with the type involved. This explanation could account for the greater degree of multiple rise in district I where spread of infection appeared to be more extensive.

In spite of the frequency of development of more than one antibody, the patterns of change in prevalence between spring and fall were different for each type studied. One type, Nancy, decreased in prevalence, with no rise to this type alone and reversion of over half of the spring positives to negative. It is reasonable to conclude that this type was not prevalent in Charleston during the summer of 1951. Increase in C-F antibody prevalence to a second type, Texas-1, was limited to the population under 5 years of age. Single rises occurred only in children of ages 1 to 3 in district IV and 1 adult in district I. No child under 4 in district IV and only 1 in district I had C-F antibody to Texas-1 in the spring. The conversion rate was highest in antibody to Connecticut-5 virus and occurred almost entirely in children under 15 years of age. Type A2 antibody prevalence was lowest in the spring and increased in all ages during the summer.

Whether or not one or more of the three viruses which showed increased antibody prevalence was causing infection during the summer cannot be determined from the C-F evidence. Coxsackie viruses were isolated from the sewage from both districts and from other areas in and around Charleston, but these strains have not been typed. Type A2 virus was isolated from stool specimens of 6 children with fever and sore throat and 2 household contacts in a block

in district IV which was not included in the serum collections. However, in the two study districts, children with paired serums tested showed a higher rate of development of C-F antibody to Connecticut-5 than to type A2, and single rises to both Connecticut-5 and Texas-1 occurred with no evidence of development of antibody to type A2. It is likely that at least 1 type in addition to type A2 contributed to the Charleston incidence, but whether or not either Connecticut-5 or Texas-1 were present is not known.

Morbidity and Coxsackie Viruses

The children in district IV who developed C-F antibody to one or more of the Coxsackie viruses studied and their household contacts reported more febrile illness and sore throat than were observed in households in which paired serums showed no rise in antibody. This excess in morbidity was most notable in August and September. The clinical syndrome in about half of the cases was similar to herpangina (6). The others were less specific. No chest pain or pleurodynia was reported. Seven of the 14 cases in individuals with conversion were associated with rise in antibody to the Connecticut-5 type only, and 4 with rise in Connecticut-5 plus either Texas-1 or type A2. Similarly, 4 of the 9 household contact cases were associated with rise to Connecticut-5 only and 3 with rises to Connecticut-5 plus Texas-1 or type A2. Since virus was not isolated from any of these individuals at the time of illness, it is not possible to say positively that any type of Coxsackie virus was responsible for the illnesses or the development of C-F antibody. It is interesting, however, and perhaps worthy of further investigation, that while the greatest

number of antibody conversions were to the Connecticut-5 virus, and the association of conversion to Connecticut-5 with minor morbidity was most marked, the minor illnesses reported were herpangina-like. The Connecticut-5 virus has been suggested as one of the etiological agents of pleurodynia (7, 8). No symptoms suggestive of this syndrome were reported.

Summary and Conclusions

1. Spring and fall prevalence of complement-fixing antibodies to four antigenically distinct Cocksackie viruses in paired serums collected in the spring and fall of 1951 from two selected population groups in Charleston, W. Va., is presented with conversion rates for each age group. Each population is relatively homogeneous, but the two differ in socioeconomic status and environmental sanitation. Antibodies to the following Cocksackie virus types were studied: Connecticut-5 (B1), Nancy (B3), Texas-1 (A4), and type A2.

2. In spite of the fact that many persons showed development of antibody to more than one type of virus, each type shows a distinct and different pattern of change in prevalence between spring and fall.

3. The conversion rate for the two types which showed increase in prevalence at all ages was definitely greater in the district characterized by substandard socioeconomic status and environment.

4. In the district selected for good sanitary environment and better than average socioeconomic status, there appeared to be an association between the development of antibody to one or more of the Cocksackie viruses and the re-

ported incidence of unclassified acute minor morbidity, particularly those illnesses with symptoms of fever or sore throat in individuals and family contacts under 10 years of age.

5. The incidence of unclassified acute minor illnesses in the total population under 10 years of age in this district during August was about 31 cases per hundred. Ten percent of the children, identified by laboratory study as individuals or household contacts of individuals who developed complement-fixing antibody to one of the Cocksackie viruses, reported incidence rates higher than the rates for the total population and accounted for about 25 percent of the morbidity with symptoms of fever or sore throat.

ACKNOWLEDGMENTS

The authors wish to acknowledge the assistance of Dorothy Davis in carrying out the complement fixation tests and Dr. Lisbeth M. Kraft.

The cooperation of the West Virginia State Department of Health and the Charleston-Kanawha County Health Department is acknowledged as is the assistance of the professional and subprofessional members of the project staff in Charleston who collected the laboratory specimens and morbidity data.

Isolation of a Coxsackie Virus During a Summer Outbreak Of Acute Minor Illness

By JOSEPH L. MELNICK, Ph.D.,
MARY WALTON, M.D., Dr.P.H.,
and IRA L. MYERS, M.D.

COXSACKIE VIRUSES have been isolated from patients with a variety of illnesses (1, 2, 3). However, the characterization of these viruses as the etiological agents of specific disease is not a simple matter. Extensive and detailed investigations were required before Huebner and his associates (4) were able to demonstrate that certain members of the Coxsackie group could induce the clinical entity known as herpangina. The fact that at least 16 antigenic types are included in the Coxsackie group (5) confuses the problem. Additional investigations combining epidemiological observations and laboratory study of specimens collected in the field are necessary to elucidate the role of these viruses in human illnesses. One such investigation is recorded here.

The observations described were made as a part of a study of the epidemiology of poliomyelitis which is being conducted in Charleston, W. Va. (See the preceding paper.) In the last week of July 1951 an unusual incidence of unclassified acute minor illness was noted in a block in one of the study areas in which households are regularly visited by in-

Dr. Myers, a commissioned officer of the Public Health Service, was assigned to the Communicable Disease Center poliomyelitis project, at Charleston, W. Va., when a part of this study was in progress. He is now with the Communicable Disease Center, Atlanta, Ga. Biographical data for Dr. Melnick and Dr. Walton will be found with the article by them on p. 1167 of this issue.

This study was aided by a grant from the National Foundation for Infantile Paralysis.

interviewers. The block is adjacent to one from which a case of poliomyelitis had been reported earlier in the week. The situation was investigated to determine whether or not the two observations were related.

Materials and Methods

Stools and paired serum samples were collected at times indicated in table 1. They were frozen at about -20° C. soon after collection and held at this temperature until tested. The methods used in the preparation of stools for testing for poliomyelitis and Coxsackie viruses, as well as the criteria for positive isolations, have been described in detail previously (6, 7, 8). For poliomyelitis virus one monkey was employed per sample, the animal being inoculated intracerebrally with a fecal extract which had been concentrated and partially purified by ultracentrifugation. Two litters of eight newborn mice each were inoculated for each test for Coxsackie virus.

Neutralization tests were carried out as described (9, 10). For the paired serums, each serum was diluted 1 to 10 and run against varying dilutions of virus. The results in table 1 are listed as the log units of type A2 Coxsackie virus (Fleetwood strain) neutralized by this dilution of serum.

The viruses isolated in this study were typed first by the plate complement fixation test as adapted to Coxsackie viruses (11) and then by neutralization with the prototype serum in order to rule out the presence of more than one strain in the isolate (5).

The Outbreak

The poliomyelitis patient, a white male 6 years of age in household 8 (see table 1) became ill on July 18, 1951, with symptoms of fever, drowsiness, nausea, and epigastric pain. He developed a stiff neck the following day. A diagnosis of poliomyelitis was made on July 20 on the basis of increased lymphocytes in the spinal fluid, stiff neck, and hamstring muscle spasm. Weakness of abdominal muscles was noted on July 21 and persisted until September 4. On July 21 his year-old brother developed fever and sore throat, at which time the attend-

ing pediatrician observed small vesicles in the throat (herpangina). On July 25 his mother reported a sore throat.

The 6-year-old poliomyelitis case played frequently with children in the adjacent study block and had attended a birthday party at the home of household 2 (see table 1) on July 4. There was no known contact with household 7.

Twelve families live in the study block. Seven were available for study. In 6 households 1 or more persons reported illness during July. Of the 10 children in these households 7 had symptoms between July 11 and 31. Six had fever and sore throat. In 2, small vesicles were seen on the first or second day of illness. The others had small superficial ulcers. The seventh reported only coryza. Morbidity reported in the block and laboratory findings are shown in table 1.

Laboratory Findings

Coxsackie virus was isolated from stools of each of six children in the study block and from the poliomyelitis patient and the younger child in that household (No. 8). By methods previously described (5) all eight strains were found to belong to type A2. The Charleston viruses reacted in the complement fixation test with type A2 serum but not with any of the other 14 prototype serums which were run simultaneously with each of the strains. Each strain was then found to be neutralized by antiserum to the prototype type A2 strain (Fleetwood). Over 100,000 doses of virus were neutralized by a 1 to 10 dilution of immune mouse serum.

One of four children from whom paired blood specimens were obtained showed a rise in titer of neutralizing antibody. No virus was isolated from stools of six adults in households with illness. All first blood specimens from the adults showed neutralizing antibody. None showed a rise in titer in convalescent blood.

Household 7 reported no illness during July. There was no known contact between children in this family and others in the block. No virus was isolated from stool specimens of 2 children and 2 adults in this family.

Poliomyelitis virus was isolated from a stool specimen from the poliomyelitis patient but not from the specimens of the sibling or from the

children in the study block. None of three pairs of serum run showed a rise in complement-fixing antibody to type A2 poliomyelitis virus.

Discussion

An investigation was made of an outbreak of minor illness which occurred coincidentally with the onset of poliomyelitis in a child during a period of low poliomyelitis incidence in Charleston, W. Va. Only three cases were reported in this area in 1951. The study was limited to one city block in which several cases of fever and sore throat (including some patients with herpangina) occurred during July 1951. Stool samples were collected as long as a month after symptoms were first noticed. If we assume that the illness was caused by type A2 Cocksackie virus, then the fact that every child tested who had been ill was found to be excreting this virus is an agreement with previous studies on the duration of Cocksackie virus carrier states. Because the first serum sample was usually taken several days after onset, it is not surprising that antibody rises could be demonstrated only in two instances. Neutralizing antibodies develop early in Cocksackie infections (6, 9), and all patients excreting Cocksackie viruses either had a high titer of homotypic antibodies in their first serums or developed them by the time the second serums were taken.

It is noteworthy that only one household with children gave negative tests for Cocksackie virus and that the children of this household had no known contact with the children of the other families studied.

In the group of five households with children currently infected, none of the adults were found to be carriers. All adults who were tested had neutralizing antibodies to type A2 Cocksackie virus. The titer of antibody in the adults did not change during the period of observation. It was slightly lower than that in the children, which suggests that the infection of the adults might not have been of recent origin. Beeman, Cole, and Huebner have recently made extensive studies in this field and have come to conclusions with which we agree: Persons with type specific neutralizing antibody do not excrete virus when it is introduced into the household, nor is there a change in their

neutralizing antibody level. Similar observations have been made on chimpanzees exposed to Cocksackie virus by natural routes (12).

There was little poliomyelitis in Charleston in 1951 and the data show how localized poliomyelitis can be in an urban area. The minor illness in the study area could not be related to poliomyelitis infection but rather to infection with one of the Cocksackie viruses. The patient who first called our attention to this area was found to be infected with both poliomyelitis and a Cocksackie virus. Although the contacts appeared sufficient for spread of Cocksackie virus within the block, no evidence could be obtained that poliomyelitis virus spread from the patient into the block. In 1950, which was also a year of low prevalence of clinical poliomyelitis, virological data also indicate the failure of the virus to spread widely through the community. Sewage tests were carried out in 1 circumscribed area of Charleston (4,000 people on the line) in which 2 cases occurred in 1 week during September. Weekly sewage samples were negative for 11 weeks before the cases occurred, and also during the week of onset. Poliomyelitis virus was isolated from the sewage the following week. After this, the tests became negative again.

Serological data on Cocksackie infections were obtained in Charleston during the summer of 1951 from normal children who were bled in the spring and again in the fall (see accompanying study). It was found that 30/83 (36 percent) of children under 10 years of age in this study area developed increases in complement-fixing antibodies to type A2 (Fleetwood), A4 (Texas-1), or B1 (Connecticut-5) viruses and to a much less degree (2/83) to B3 (Nancy). Of the 13 children with antibody to type B3 in the spring, 8 showed no antibody in the fall. Children developing Cocksackie virus antibodies had a significantly higher incidence of fever and sore throat than children who failed to develop these antibodies. Because of the heterotypic complement-fixing antibody response occurring in Cocksackie infections, it is not possible to say which virus was responsible for the antibody increases in the Charleston children. The isolation here of type A2 Cocksackie virus from children with similar illnesses during the same period sug-

gests that the type A2 virus may well have been one of the major etiological agents for the minor illnesses prevalent in Charleston during the summer of 1951.

Summary

A localized summer outbreak, presumably of herpangina, was investigated in Charleston, W. Va., during 1951.

Acute minor illnesses with symptoms of sore throat and fever were reported by the sibling of a case of poliomyelitis and by 6 of 10 playmate contacts under 10 years of age living in the block across the street. Some of the children had a syndrome compatible with herpangina. Both poliomyelitis virus and type A2 Coxsackie virus were isolated from a fecal specimen from the case of poliomyelitis, and a rise in neutralizing antibody titer to type A2 Coxsackie virus was demonstrated. Stool specimens from household and playmate contacts with symptoms were found to contain type A2 Coxsackie virus but not poliomyelitis virus. Adult members of the households possessed neutralizing antibodies to type A2 Coxsackie virus. None were found to be excreting virus.

ACKNOWLEDGMENT

We wish to express our thanks to Dr. M. V. Gallagher who reported the clinical observations in the study block and in the household of the poliomyelitis patient.

Research Preferences and Activities Of Public Health Service Officers

By SIDNEY H. NEWMAN, Ph.D., and MARGARET A. HOWELL, M.A.

PUBLIC HEALTH SERVICE professional personnel—commissioned officers and civil service—engage in four major types of health activities: research, clinical or medical care, administrative, and public health (for example, consultation on State health programs and developing disease control programs). Research activities are both basic and applied. They are performed in laboratory, field, or clinical situations and are concerned with such problems of health and disease as etiology, therapy, and control.

Achieving the best in-Service placement in the four areas of Service activity requires

Dr. Newman, the chief of the research branch, Division of Commissioned Officers, Public Health Service, was an academy psychologist with the United States Coast Guard Academy from 1943 to 1947. Dr. Newman is a diplomate in clinical psychology, American Board of Examiners in Professional Psychology, and a member of two research psychology panels of the Board of Examiners, United States Civil Service Commission.

Miss Howell is with the Division of Commissioned Officers as a research psychologist in the branch headed by Dr. Newman. She received her master's degree from the University of Rochester in 1949 and earlier worked at the university as a research assistant in leadership studies. Miss Howell joined the Public Health Service in 1950.

knowledge of employees' interests and training. In the research area, the need for readily available information on work preferences was recently highlighted by the staffing requirements of the newest research programs of the Public Health Service, those operating in the Clinical Research Center of the National Institutes of Health, in Bethesda, Md.

To meet this need among commissioned personnel, a questionnaire was designed to identify the officers interested in doing research and to determine their specific interests in defined areas of investigation. As an aid to administrators in making a quick initial screening of officers who might be assigned to research activities, the questionnaire also asked each officer to indicate his years of training and experience in research and other work areas. Background characteristics of those officers who, on the basis of questionnaire responses, appear adequately prepared for research positions could then be more completely evaluated from the records of training and experience contained in the personnel files of the Division of Commissioned Officers.

This report summarizes the salient findings from an analysis of the questionnaire responses, furnishing an overview of the research activity of the Public Health Service commissioned corps and identifying its research potential as indicated by expressed work preferences. The data may also be useful to individuals dealing with that phase of the Nation's manpower prob-

lems involving the identification and utilization of research personnel. Some attention is devoted to the methods for collecting and using the information in dealing with staffing problems since these methods could be extended to other organizations and other types of personnel activities.

Methods

The research interest questionnaires and instructions for their use were mailed in May 1952 to the 2,589 regular and reserve officers who were on active duty in the Public Health Service. Followup letters were sent a month later to officers who had not returned the forms. Of the questionnaires distributed, 2,278—88.0 percent—were included in the study; 298—11.5 percent—were not returned; and 13—0.5 percent—were returned too late to be included in the tabulations.

The questionnaire was of the self-coding type. It was designed so that it could be easily and quickly completed, would yield the complex information desired, and would furnish information that could be processed by machine tabulation methods.

Information from the questionnaires was disseminated to employers of officer research personnel in the Public Health Service through the compilation of three listings. The listings were arranged to answer the three major questions which these employers could be expected to ask: Who are the officers interested in doing research? On what disease or condition would each officer prefer to work? In what discipline or field is each officer most interested in working?

To answer the first question, officers were grouped according to their responses to the questionnaire—not interested in research, satisfied to do research, glad to do research, and preferring research to any other field. The second and third questions were answered by grouping officers according to their first research choices indicated from a list of 134 diseases or conditions and 197 disciplines or fields. Write-in first choices were listed separately. Within each of the 3 listings, officers' names were arranged first by profession, then by rank, and last, alphabetically within rank.

The prepared listings thus enable Service employers to locate rapidly individuals who might possibly fill research vacancies. By consulting the listing arranged by first choice of disease or condition, they can immediately locate the names of all officers in the Public Health Service who are interested in doing research on, for example, malignant neoplastic diseases. At the same time, they can see which officers have had sufficient training and experience to warrant further consideration by a review of their personnel files.

General Interest in Research

In considering the statistical results from the study, it is well to bear in mind that the data are based on officers' evaluations of their own training, research interests, and current activities. The generalizations which may be derived from an analysis of questionnaire responses could differ somewhat from those which might be made in other types of appraisals of current officer research potential and activities. Further, the current research interests reported by officers are not to be regarded as immutable. While it may be assumed that interests in broad occupational areas in the health field, such as medical care, public health, or research, will remain fairly constant, expressed specific interests may be influenced by such factors as an officer's present assignment or his estimation of future needs of the Public Health Service.

Where available, comparative percentages of other groups engaged in research are included in this report. Strict comparisons of the Public Health Service group with other groups cannot be made since conditions under which information was obtained were not necessarily the same and since Service officers could possibly constitute a part, though a small proportion, of some of the other groups. The comparative data, however, may be helpful in providing a frame of reference for the material in this report.

Research Potential

Summary data on officers' research interests and activities are presented in table 1. From this table, it may be seen that 27 percent of officers in the study report that they are cur-

rently engaged in research. Most of these, 24 percent of the total group, say that they are in research and like it. Only 3 percent of all the officers indicate that they are currently engaged in research and are not satisfied with their present type of assignment. Of the officers included in the study, 73 percent state that they are not in research assignments; 31 percent indicate that they are not in research assignments but would be satisfied or glad to do research. As measured in terms of expressed interest, this 31 percent represents the personnel research potential of the commissioned corps. If, then, new research vacancies occur, either because of expanding research activities

or because of transfer of officers in research to other activities, this group of 712 commissioned officers can be evaluated for research assignments.

The 42 percent who say they are not performing research and do not wish to do so may be eliminated from consideration for research activities. These officers are needed in the public health, medical care, and administrative functions in which they may be presumed to be interested.

Comparison of Categories

¹ At time of completing the questionnaire.

² There are 10 major categories of commissioned officers in the Public Health Service; 2 categories, scientist and sanitarian, are each subdivided into a number of professions.

³ Physical and occupational.

research are the categories of scientist—80 percent, veterinarian—59 percent, and sanitarian—39 percent (see table 1). The scientist and sanitarian categories of the Service are composed of a number of scientific professions (1). Because of the small numbers of officers in each profession in these two categories, percentages engaged in research are based on all professions within each category.

Of the scientific professions represented in the scientist and sanitarian categories of the Public Health Service, data are available on the research activity in certain of these professions in this country (2-4). With respect to the members of these professions who have the doctorate, as is required of scientists in the Service, 55 percent of the chemists, 42 percent of the physicists, and 12 percent of the psychologists report that they are engaged in research. With regard to professional groups in this country who have the degrees required for the sanitarian category—in this category the master's degree is required for commissioning in the Regular Corps and the bachelor's for the Reserve Corps—the following data on percentages engaged in research are available (2-4): chemists with the master's degree—49 percent, with the bachelor's degree—41 percent; physicists with the master's—44 percent, with the bachelor's—61 percent; psychologists with the master's—12 percent. (Psychologists with the bachelor's degree are usually not eligible for research positions.) In all degree levels, 51 percent of chemists in government and 71 percent of physicists in government report that they are engaged in research.

The 59 percent of veterinarian officers reporting research activity suggests that the work of Service veterinarians differs from that of other groups of veterinarians. An estimated 7 percent of the veterinarians in the United States are engaged in teaching and research, exclusive of the approximate 1 percent who are doing research in the Federal Government and in commercial organizations.

Of Service officers engaged in research, the medical (24 percent) and sanitary engineer (24 percent) categories contain the inbetween percentages. Medical officers engage in all four types of Service activities—research, medical care, public health, and administrative. Sani-

tary engineer officers engage in all except medical care. Data are not available on the research activity of physicians in this country. A greater percentage of Public Health Service sanitary engineers, however, state they are doing research than do sanitary engineers in general. Only 2 percent of the sanitary engineers in this country report that they are engaged in research (5).

Authoritative estimates are available on the percentages of all engineers and scientists combined who are engaged in research in this country. About 25 percent of engineers and scientists were in research in 1952, and about 35 percent of engineers and scientists in the Federal Government were engaged in research in 1951 (6). Keeping in mind the previously mentioned reservations concerning comparisons of Service and other groups, one may note that 42 percent of Service officers in the combined scientist, sanitarian, and sanitary engineer categories are engaged in research.

It is easy to understand why relatively small proportions of nurse (15 percent), dental (14 percent), dietitian (10 percent), pharmacy (9 percent), and therapy (6 percent) officers are engaged in research in the Public Health Service. Officers in these professions are usually employed for medical care, public health, and administrative assignments. Informed estimates are available on the percentages of some of these professions that are engaged in research in the United States. Presumably, these indicate that a higher proportion of Service officers in these professions engage in research than do members of these professions in general. Nurse researchers are as yet few in number. Approximately 1.5 percent of the members of the American Dietetic Association are doing full-time research. About 4 percent of the members of the American Pharmaceutical Association are actually engaged in research, and an estimated additional 1 percent are engaged in teaching and research.

Considering officers' preferences for research, it may be seen that the order of the percentages of officers within each category preferring research closely parallels that of the percentages within each category doing research (see table 1). There are large differences between categories in the proportion of officers preferring

research. As is to be expected, scientist officers are the most research-minded group: 97 percent prefer research. Next in order are the veterinarian, sanitarian, sanitary engineer, and medical officers.

Preferred Areas of Research

The specific areas in which research-interested officers would like to work were determined by asking officers to indicate their preferences for various kinds of research operation, such as laboratory or clinical, and for various disciplines or fields of study. Preferred areas of research are summarized in table 2 in which the 197 disciplines originally listed for use with the questionnaire have been grouped in 8 general fields.

Of the total number of officers interested in performing research, most show preference for these types of research operation: clinical in-

vestigation (20 percent), combined laboratory-clinical (16 percent), laboratory (16 percent), laboratory-field (12 percent), and field (12 percent). Relatively little interest is shown in such types of research as the combined field-clinical (6 percent), administrative (5 percent), and statistical surveys and analyses (2 percent).

The highest preferences by discipline are in the medical (43 percent), biological-medical (15 percent), engineering-sanitation (14 percent), and biological (12 percent) fields. The pattern of discipline preferences fits fairly closely that of preferences for operational areas. This is to be expected since many disciplines tend to fall into specific operational areas. As examples, research in the medical field is likely to be in a clinical area of operation, and biological-medical research is likely to be in a combined laboratory-clinical area.

Table 2. Commissioned officers (1,259) preferring ¹ to do research in various operational areas and in various disciplines

¹ First choice.
² Differences between those doing and not doing research are significant at the 1-percent level.
³ Differences between those doing and not doing research are significant at the 5-percent level.

Preferences of the research-interested officers who state that they are currently engaged in research are different from those of officers who are not in research. In areas of research operation, the former group definitely prefers laboratory research (32 percent), a combination of laboratory and field (15 percent), and laboratory and clinical combined (15 percent). Officers not doing research lean toward clinical investigations (29 percent). Combined laboratory-clinical (18 percent), field (13 percent), and combined laboratory-field (10 percent) are next in order of preference (see table 2).

In the discipline choices, research-interested officers not in research are significantly more interested in the medical field (55 percent) than are the officers doing and preferring research (28 percent). Significantly more of the latter group, those who perform and prefer research, however, show interest in the biological-medical, biological, and chemical fields. Preferences for the engineering-sanitation and remaining fields are fairly close for the two groups.

Preference differences of officers reporting that they are currently in research and those not in research may be partly accounted for by the fact that proportionately more scientist, sanitarian, and veterinarian officers who prefer research are engaged in it than are medical officers who prefer research. By reference again to table 1, one may see that of the 547 officers preferring and doing research, 200 (37 percent) are in the scientist, veterinarian, and sanitarian categories, and 244 (45 percent) are in the medical category. By contrast, of 712 officers preferring but not doing research, only 76 (11 percent) are in the first 3 categories, while 382 (54 percent) are in the medical category. It is not surprising, then, that a higher percentage of officers who are interested in research but are currently not engaged in this activity would like to work in the medical or clinical areas than would officers interested in and now doing research.

The preferences in disciplines and areas of research operation expressed by the total group of research-interested officers reflect to some extent the professional composition of the Public Health Service. If it is presumed that the

professional structure within the Service has developed from the activities and needs of the Service, then it is not surprising that the expressed preferences of the group studied fit well the present and anticipated work of the organization. In the past, laboratory, combined laboratory-field, and laboratory-clinical types of studies have tended to receive emphasis. With the opening of the Clinical Research Center in July 1953, an increase in the clinical type of investigation and more opportunity for integrated laboratory-clinical work can be expected.

Preferred Research Problems

One part of the questionnaire asked officers interested in research to describe in narrative form the kind of research problem on which they would like to work. These descriptions are available to Service employers of research personnel. In addition, more general information on preferred research problems was obtained from the choices that the officers indicated for diseases or conditions on which they would like to do research. The disease research preferences for those officers expressing interest in doing research are shown in table 3. For the table, the list of 134 diseases or conditions used with the questionnaire has been divided into 19 general groups based on a modification of a standard classificatory system (7).

A comparison of the preferences indicates that proportionately more officers not doing research than those in research prefer to work on problems dealing with psychological disorders, diseases or conditions of the respiratory system, and organs of special sense. A greater proportion of those indicating that they are in research than of those not in research would like to investigate infections by lower organisms, infections by higher plants or animal parasites, and disorders of metabolism, growth, or nutrition. Generally, however, there is good agreement between the disease work preferences of the two groups of officers.

The 1,259 officers interested in research prefer to work on the following diseases or conditions as classified in table 3: vectorborne diseases (13 percent), infection by lower organism (11 percent), psychological disorders (9 percent), car-

¹ First choice.

² Where not mentioned, the words "diseases or conditions of" may be understood, for example, "Cardiovascular system, diseases or conditions of."

³ Classified under "Diseases of the body as a whole," but considered separately here.

⁴ Difference between those doing and not doing research is significant at the 1-percent level.

⁵ Difference between those doing and not doing research is significant at the 5-percent level.

⁶ Diseases or conditions not in list but written in as first choice.

diocvascular system (9 percent), new growths (8 percent), and the digestive system (8 percent). These preferences coincide to a considerable degree with the various kinds of research in which the Public Health Service is engaged, as for example, studies of vectorborne diseases and infections by lower organisms at the National Microbiological Institute, Rocky Mountain Laboratory, Communicable Disease Center, and Environmental Health Center; psychological disorders at the National Institute of Mental Health; diseases of the cardiovascular system at the National Heart Institute; new growths at the National Cancer Institute; and diseases and conditions of the digestive system at the National Institute of Arthritis and Metabolic Diseases. Officer preferences for research on psychological disorders, cardiovascular diseases, and new growths also fit well the anticipated work of the new Clinical Research Center.

Training and Experience

The questions on training and experience were designed not to duplicate personnel records but to make information relevant to the screening of research officers easily available. The information supplied by officers interested in doing research is summarized in table 4. These officers were grouped into areas according to the functions in which they had advanced training and professional experience regardless of their professions or occupations. Since each officer could indicate training or experience in more than one area, the percentages given are the percentages of all officers marking that area.

More than half (56 percent) of the officers interested in and doing research reported advanced or specialized training in the research area, while only 18 percent of those interested in but not doing research stated they had such

Table 4. Advanced or specialized training and professional experience of 1,259 commissioned officers interested in doing research

¹ Difference between officers doing and not doing research is significant at the 1-percent level.

² Difference between officers doing and not doing research is significant at the 5-percent level.

³ Statistics is a method used by many officers, but it is the major functional area of only a few commissioned officers in the Public Health Service; therefore, it is included under training but not under experience.

training. A sizable portion (44 percent) of officers interested in, and currently engaged in, research indicate no advanced training in research. These officers, however, have had to satisfy the basic academic and professional training requirements of their profession, such as the doctorates in medicine, dentistry, and veterinary medicine, in order to be eligible for the commissioned corps. While such training does not necessarily equip these officers for research, proficiency in research may be gained in positions offering adequate opportunities and supervision. Although not shown in table 4, it is noteworthy that 44 percent of research-interested officers engaged in research have advanced degrees beyond those required for commissioning while 29 percent of those not in research have such degrees. The percentage difference is significant at the 1 percent level.

The total group of officers expressing interest in research have obtained most of their advanced training in three areas: research (35 percent), public health (21 percent), and clinical medicine (16 percent). These officers lack advanced or specialized academic training in administration (5 percent) and statistics (3

percent). It is likely that many of them have received some training in statistics but did not consider it advanced or specialized. It is doubtful, however, that many have had much advanced academic training in administration.

That research experience is also an important differential factor in the background of those officers performing research may be seen from studying table 4. Of the officers expressing interest in research, a markedly higher proportion of officers engaged in research than of those not in research have had 1 or more years of research experience inside or outside the Service—87 percent as contrasted with 31 percent. Those research-interested officers who indicate that they are not in research have a higher proportion of clinical experience (61 percent) than do those in research (44 percent). The group interested in but not doing research also has higher percentages of officers with public health experience and administrative experience.

Summary

The foregoing demonstrates the feasibility of determining the research and other interests and qualifications of an organization's person-

nel by questionnaire and statistical methods. It describes how such information may be made conveniently available to those who utilize research personnel.

Public Health Service officers are a research-minded group. The numbers discovered who report that they are interested in, but are not doing research, now constitute a known research personnel potential of the commissioned corps.

Regardless of their present assignment, officers interested in research prefer clinical, laboratory-clinical, and laboratory types of investigations in medical, biological-medical, engineering-sanitation, and biological fields. They are interested in doing research on a number of different diseases or conditions and show the greatest preference for research on vectorborne diseases (general), infections by lower organisms, psychological disorders, diseases of the cardiovascular system, and new growths.

It is of significance that officers who are interested in research activities, and who are already in the research field, have had more advanced or special training in research, more degrees beyond those required for commissioning in the commissioned officer corps, and more research experience than officers who are interested in, but are not engaged in, research.

ACKNOWLEDGMENTS

Information and estimates concerning the percentage of other professional groups engaged in research

were furnished through correspondence by Kenneth S. Colmen, Research and Development Board, Department of Defense; Robert P. Fischelis, American Pharmaceutical Association; Dr. C. D. Van Houeving, American Veterinary Medical Association; Ruth M. Yakel, American Dietetic Association; and the research and statistics unit of the American Nurses' Association.

Public Health Service Advisory Councils

Dr. Howard A. Rusk, chairman of the Department of Physical Medicine and Rehabilitation, New York University College of Medicine, has been appointed a member of the National Advisory Arthritis and Metabolic Diseases Council. The Council's recommendations are the basis for Public Health Service research grants in arthritis and metabolic diseases. Dr. Rusk, internationally known for his work in the field of rehabilitation, and for medical articles,

includes among his activities the chairmanship of the Health Resources Advisory Committee of the Office of Defense Mobilization and the chairmanship of the National Advisory Committee to the Selective Service System. Since 1946, he has been an associate editor of the New York Times. In 1952, he received the Lasker Award of the American Public Health Association, and in 1953, the Dr. C. C. Criss Award for his work in rehabilitation.

Studies on Dental Care Services For School Children

—First and Second Treatment Series, Woonsocket, R. I.—

By FRANK E. LAW, D.D.S., M.P.H., CARL E. JOHNSON, D.D.S.,
and JOHN W. KNUTSON, D.D.S., Dr.P.H.

THE WOONSOCKET, R. I., school dental service program provides information on how the problems of accumulated and maintenance dental care needs of school children were met in a specific segment of the population. A cooperative study project of the city of Woonsocket, the Rhode Island State Department of Health, and the Public Health Service, the program was designed to supply complete dental services, except orthodontics, to all school children enrolled in kindergarten through the ninth grade of the public and parochial schools, provided treatment was requested by a parent or guardian.

The Woonsocket study was similar in purpose and procedures to a study conducted in

Richmond, Ind., between December 1946 and December 1951 (1). Possible regional variations in the size of the dental care problems and in the resources available suggested comparative studies to determine the magnitude of these variations and methods of overcoming them. Dental caries prevalence proved to be one-third greater in Woonsocket than in Richmond and missing tooth rates almost twice those in Richmond. About the same amount of dental care in proportion to need (F/DMF) had been received by the children in each city prior to the initiation of the programs.

Woonsocket, a fairly representative New England industrial community in northern Rhode Island, was chosen as the location for this study for several reasons. Its relatively stable population of approximately 50,000, 99 percent of whom are white with French-Canadian stock predominating, provided between 6,000 and 7,000 school children for the study. The program had the official approval and cooperation of the Rhode Island State Department of Health, the city authorities, the State and local dental societies, and the public and parochial school systems. A relatively high dental caries attack rate is common in this region (2).

Planning of the program, purchase of equip-

Dr. Law, regional dental consultant for Region III of the Department of Health, Education, and Welfare, directed the dental research program in Woonsocket, R. I., from 1945 to 1948. Dr. Johnson, now a member of the staff of the Public Health Service outpatient clinic in New York City, was a member of the Woonsocket program staff from 1945 to 1948 and directed the program from 1948 to 1952. Dr. Knutson, an Assistant Surgeon General, is the chief dental officer of the Public Health Service.

ment, selection of space, and preparation of clinic rooms were begun in the fall of 1945. The first clinics were opened on January 14, 1946, and the study was concluded 6¾ years later.

Since the majority of dental defects in any group of children results directly from dental caries, this study, like the one in Richmond, was concerned principally with caries prevalence and the treatment services required to correct carious defects. To facilitate comparison between the studies in the two cities, the data on the Woonsocket study are presented in a pattern similar to that used in the Richmond report.

Clinic Facilities and Personnel

Dental clinic rooms were selected and prepared with the necessary plumbing and electrical outlets in 24 of the city's 27 schools: 15 public, 8 parochial, and 1 orphanage. The size of the clinics varied from 2 to 7 dental chairs, depending upon school enrollment and the space available. In most schools, attractive, well-lighted rooms were provided, although in two small elementary schools, it was necessary to put up temporary partitions in classrooms.

Two modern standard dental units, 2 junior chairs, 2 operating stools, and an instrument cabinet containing duplicate sets of instruments were the basic equipment for each dentist. Operating lights on the units, an X-ray machine, sterilizer, and additional equipment completed each dental clinic. The arrangement of the equipment and the provision of adequate auxiliary personnel encouraged each dentist to work from a seated position at all times. These working conditions were designed to reduce fatigue and to improve the quality and quantity of the dentists' services (3).

Organization and scheduling was planned to maintain 3 clinics in operation throughout the school system at one time. When dental treatment was completed in one school, the equipment, supplies, and personnel were transported to the clinic room in another school. The average clinic was dismantled, transported, and set up ready for use in the next school in approximately 1½ days.

Project personnel included 4 to 7 dentists, 1 or 2 dental hygienists, 8 dental assistants, 1 fol-

lowup worker, 1 secretary, and 3 clerks. The dental hygienists gave prophylaxis and topical fluoride applications. The followup worker checked on treatment certificates from patients of private dental practitioners, encouraging these as well as clinic patients to obtain complete treatment. In addition, she transported to a clinic children needing emergency treatment or children whose treatment had not been completed when the clinic was moved, and she delivered supplies. The secretary cared for the central office and supply room. A clerk was assigned to each clinic to handle records, maintain the flow of patients, and perform related duties as required. An average of 1½ dental assistants for each dentist was on duty in each clinic.

The 8 dental assistants employed at the start of the study received 10 weeks of intensive training at the Naval Dental School in Bethesda, Md. They in turn helped to train assistants employed as replacements from time to time as the study progressed. The entire staff received inservice training at irregular intervals from each of the seven dental consultants

to the program, who also served the Richmond project. The consultants were experts in pedodontics, dental materials, and the use of auxiliary personnel.

Clinic Routine

Before a clinic was installed in a school, dental examination records were obtained for the entire school population. Teachers issued "request for treatment" slips to all pupils with instructions to return them signed by a parent or guardian, indicating whether he wanted the child's dental care provided in the school clinics or in the offices of the family dentist. Care in the school clinics was requested for about 85 to 87 percent of the children enrolled.

The dental-care program was divided into four consecutive treatment series. A treatment series consisted of dental examination of the total enrollment, kindergarten through junior high school, and completed treatment of all children whose parents requested treatment. This report is limited to the first and second treatment series for children receiving care in the school dental clinics.

Examination

Complete dental examinations of all children were made in each school. Examinations were made with a No. 4 plain mouth mirror and sharp No. 5 double-end explorers. X-rays were used whenever there was any doubt about clinical diagnosis.

The following information was recorded on examination records maintained for each child during each treatment series:

Number of primary and permanent teeth erupted and unerupted.

Number of teeth missing because of extraction.

Number of teeth indicated for extraction.

Number of roots remaining.

Number of unfilled carious teeth and the surfaces involved.

Number of filled teeth and the surfaces restored.

Observations were made on all teeth present in the mouth. Teeth recorded as carious were those which showed actual cavities, no matter

Figure 1. Dental caries prevalence in permanent teeth, first treatment series, Woonsocket, R. I., ages 5-16.

how small, as well as deep pits and fissures in which the explorer penetrated with pressure and resisted removal.

A dental assistant recorded the information on the record cards in code to facilitate transfer to punch cards for processing and analysis. A serial number was assigned to each child for the duration of the study project. A master card index system was maintained to simplify reference to a child's previous dental record.

Treatment

Once the examinations had been completed, clinical treatment was given to all children whose parents had signed consent slips. During treatment the children received chairside instruction in oral hygiene.

Clinics were operated on a year-round basis, with appointments for treatment continuing during vacations and holidays. Young children were treated in the early forenoon and the older children received the later appointment times. Extractions were generally avoided during a child's first dental experience. Efforts were made to complete all operative treatment in the teeth of at least 1 mouth quadrant during a single sitting. Treatment periods varied from 15 to 30 minutes for younger chil-

dren and from 15 minutes to 1 hour for the older children.

The types of treatment included:

Permanent fillings (amalgam and silicate cement).

X-rays as required during treatment.

Vital partial pulpectomies of permanent and primary teeth.

Root canal therapy of permanent anterior teeth.

Extractions.

Treatment of periodontal diseases.

Prophylaxis.

Topical fluoride applications.

Polishing of fillings.

The amount and type of treatment given each child were noted on the record cards. Each dentist and dental hygienist recorded all of their clinical services on daily work sheets. At the end of each 10-day working period these sheets were combined in a biweekly report showing an accurate running account of services performed during the study project.

During the first treatment series, a total of 6,848 children, 5 through 16 years of age, representing 96.5 percent of all children in kindergarten through the ninth grade, received dental examinations; 5,944, or 87 percent of those examined, requested and received dental treatment in the school clinics. In the second treatment series 6,107 children in the above age groups, or 99.7 percent of the total, were examined; 5,189, or 85 percent, of these requested treatment in the dental clinics. About 2,500 children received initial care in the second treatment period. The number of children not receiving care in the school clinics was essentially the same in both series (table 1).

Comparison of Caries Prevalence

The average annual increment of decayed permanent teeth, estimated from the difference in prevalence rates at individual ages, was 1.31 teeth per child in the first treatment series and 1.43 teeth per child in the second.

To measure and express the workload for this study adequately, all teeth requiring fillings, whether or not they had previously been filled, were counted as "caries." Teeth indi-

affected. In the two rounds, there were totals of 32,359 and 25,544 carious teeth involving about 58,318 and 41,376 surfaces, respectively.

As shown in table 2 and figures 1 and 2 the age specific DMF (decayed, missing, and filled) rates for permanent teeth increased in the first series from 0.41 at age 5 to 14.99 at age 15; in the second, from 0.48 to 16. At the start of the first series the average 15-year-old had 11.88 carious teeth, 2.67 missing teeth, and 2.33 filled teeth. The examination for the second series showed a decrease in carious teeth (8.31) and missing teeth (2.05) and a significant increase in filled teeth, from 2.33 to 8.62, for the average 15-year-old.

Twenty-two percent of the children in the first treatment series had one or more extracted permanent teeth; the corresponding figure for the second series examination was 18 percent.

Only 20 percent of the children had one or more filled permanent teeth on examination in the first round, but the percentage increased to 58 in the second series.

Of the primary teeth examined, 47 percent were found carious in the first series. The average 7-year-old had 12.7 primary teeth, of which 6.30, or nearly 50 percent, were decayed

(table 3). Only 4 percent of the group had one or more primary teeth which had been filled prior to the first treatment series. Examination prior to the second treatment series demonstrated only minor improvement in care of the primary dentition. The number of primary teeth filled increased from 709 in the initial round to 1,107 in the second.

During the initial treatment series the main concern was care of the accumulated defects of the permanent teeth; primary teeth received only emergency or very selective treatment. In spite of the high caries attack rate and the time required to complete the first treatment series (30 months), this policy was modified to a considerable extent in the second round. As shown in table 4, the number of primary teeth filled per child during the second round was more than 10 times as large as the number during the first.

Of the children requesting clinic care, 88 percent in the first series and 98.6 percent in the second received complete treatment; 78 percent and 87 percent of the children treated received fillings in one or more permanent teeth. More than 17 percent had at least one or more permanent teeth extracted during the first series, but only 9 percent of the children required extractions the second time around. The 684 permanent teeth which were extracted in the second series indicate considerable improvement over the 1,778 extracted during the initial treatment series.

The total number of permanent teeth filled in the first and second series was 25,939, and 24,682, respectively, averaging 4.60 and 5.08 teeth per child for all age groups. The average 15-year-old had 9.60 surfaces on 5.72 teeth restored during the initial treatment and 7.77 teeth involving 12.67 surfaces received fillings in the second series (table 4).

Selective treatment of primary teeth resulted in a total of 530 primary teeth filled in the first series and 4,140 in the second. Extractions of primary teeth numbered 5,131 and 4,391.

Additional treatment included 900 pulp capings and 29 vital partial pulpectomies on permanent and primary teeth during the first period. These treatments numbered 1,163 and 214, respectively, during the second series.

¹ Average of the rates for ages 5-16.

Every child received at least 1 dental prophylaxis during each round. In the second period an attempt was made to provide every child with a series of 4 topical fluoride applications; a total of 5,016 children received this treatment.

Dentist Man-Hours

During the first treatment series a ratio of 1 dentist to 384 children treated per year resulted from an average of 6.2 dentists on duty in the program. During the second series an average of 5.5 dentists operating produced a ratio of 1 dentist to 470 children treated per year. This staffing average is based on a full 65-hour, biweekly period for all dentists assigned during both series with no deductions made for administrative work, vacations, illness, training, or other nonclinical activities.

Dentist man-hour rates were determined from the total clinic time actually worked by all dentists during the 30 months required for the first treatment series and the 24 months for the second. During the first round 3.3 dentist man-hours were required to complete the treatment of each child, but in the second round only 2.8 dentist man-hours, or 86 percent as much time as in the first, were needed for this work. The average number of permanent teeth treated per dentist man-hour was about the same in both series: 2.1 in the first and 1.9 in the second. However, the 0.7 primary teeth treated per dentist man-hour in the second series was an increase of 140 percent over the number treated per dentist man-hour in the first period.

The reduction in the second treatment series of 0.5 dentist man-hour required to complete the treatment of each child resulted primarily from the lower prevalence of carious teeth and to improved operating and clinical procedures. This reduction would undoubtedly have been greater had there not been constant addition of new patients with practically no previous dental treatment and had the time (2½ years) between the two treatment series been less.

Summary

Dental examination and complete dental treatment were given 5,944 children in kindergarten through the ninth grade in the first treatment series and 5,189 children in the second

treatment series of the Woonsocket, R. I., dental care study.

The first treatment series, covering a total of 30 months, was designed to care for the accumulated dental needs of the group, with primary emphasis on care of defects in permanent teeth.

The second treatment series, requiring 24 months, was designed to treat the increment of defects occurring between treatment periods and to provide substantially more care for the primary dentition. The proportion of children requiring fillings during the second round was no less than in the initial series. In addition to the increment of defects occurring subsequent to treatment in the first series, about 2,500 children received initial care in the second series.

Only 20 percent of the children had any permanent teeth filled prior to the first series; this figure increased to 58 percent at the start of the second.

Examinations for the second treatment period demonstrated that the average 15-year-old had 8.62 filled teeth, compared to only 2.33 at the start of the first series.

In all age groups, 1,778 permanent teeth were extracted in the first series and only 684 in the second.

There was a reduction of 14 percent in the number of dentist man-hours required to complete the treatment of each child: 3.3 dentist man-hours were required in the first series and 2.8 in the second series.

RECORD and REPORT SYSTEMS **in local health departments**

with contributions from
 Chapel Hill, N. C.,
 Charleston, W. Va.,
 and Portland, Maine

Among the building stones essential to the creation of an effective structure for public health services are records and reports. Recent broadening of local health department responsibilities and changing public health practices have underscored the importance of rational records and reports systems and procedures in developing, focusing, and administering services, as well as in analyzing and measuring the effectiveness of those services.

Changes in function of local health departments are reflected in the responsibilities of the professional staff. Emphasis on the individual and the family, concentration on control programs for long-term diseases, and specialization in professional fields have intensified the demand for records and reports that will aid the health department staff in giving and evaluating the services for which the department is responsible. Records and reports must therefore be designed to permit qualitative and quantitative analysis of the health services to individuals, families, and the community and to facilitate periodic appraisal of each of the health department's programs.

Considerations such as these underlie the three discussions of local health department records and reports which comprise this symposium. Quite different points of view are expressed by the authors but they and the recently published Public Health Monograph No. 15 (see *Public Health Reports* for November, pp. 1078-82) may stimulate further suggestions of ways and means by which health department records can be more effectively utilized.

Rough sketches of proposed forms were drawn and presented by various participants from time to time. Some were accepted in part or in whole; others were rejected. The rejected sketches were redesigned and presented again. By this process there emerged for experimental use a master card, a family folder (containing a family data sheet and a family service narrative form), and an individual observation record.

These forms comprise the basic simplified service records. They provide for a summary of all clinical and nursing services to an individual, a record of pertinent information on the family as a unit, a narrative record of each service to an individual member or to the family as a group, and a record of all clinical services to an individual.

Master Card

The master card, an 8- by 5-inch form designed for use on both sides, summarizes all services provided for an individual. Each person registered with the department has such a card. Sometimes it is the only record for the individual. It combines information formerly recorded on six separate forms, namely, birth summary, immunizations, index, laboratory diagnostic services, X-ray reports, and death summary. It also provides for recording single visits or limited services to avoid opening and closing another record.

The first section of the card has space for identifying information, including name, race, sex, date of birth, registration number, name of father or husband, name of mother or wife, and mailing address.

The second section replaces and is identical to the former immunization card, with the addition of write-in spaces for immunizations which may be introduced in the future. It includes lines for recording by date immunizations for whooping cough, diphtheria, tetanus, smallpox, and typhoid.

The third section, a summary of basic records, compares with the old index card. It has columns for the date of first admission to a service, the type of service, the name of the basic form on which the service is recorded in detail (family service narrative, individual ob-

servation record, tuberculosis program register, or orthopedic clinic record), the file in which the form may be found, and the date the service is terminated.

On the reverse side of the card, miscellaneous services not recorded elsewhere are listed. To the left are 3 columns, 1 each for date, type, and result of a test or service; the remainder of the space—over half the width of the card—is for remarks. Here may be summarized data on negative laboratory reports, negative X-ray reports, the issuance of health cards, and other limited services, and data on deaths.

The Family Folder

The family folder is a lettersize manila folder of special cut labeled to show the name of the head of the family. This size folder makes it possible to insert all records without folding and to include patient and family correspondence as well as service records.

Family Data Sheet

The family data sheet was designed as a separate record to permit the replacement of worn or soiled folders without the necessity of copying the information and to encourage the typing of the record, particularly the identifying information and family roster.

This sheet provides a summary of pertinent data on the family as a unit. Following a section for identifying information at the top of the sheet is a section for a complete roster of family members. After each name in this list is space for sex, date of birth, and changes in status, such as marriage, entrance into the armed services, or departure from the home for other reasons, by date.

A section on both sides of the form equivalent to a full page is provided for the narrative recording of significant economic and social data. In this section extra-family members living in the home are accounted for in terms of their influence upon the family life. If one of these members receives service, a folder is opened for him. The objective of this arrangement is to encourage the study of families as units.

At the bottom of the form on the reverse side is a section for the chronological summarization of the various services provided for individual members of the family.

Family Service Narrative

The family service narrative form is an 8½- by 11-inch sheet ruled on both sides. At the top is a space for family identification. In a column at the left are entered the date, place of visit, type of service, and individual served. Routines normally associated with the specific type of visit are recorded in a predetermined order set forth in the records guide prepared as a part of the project. This makes it possible to find these data without reading the complete narrative statement. Each narrative entry is signed by the person performing the service recorded. All visits to individual members of the family and to the family as a unit are recorded in chronological order on the same form. This system is an improvement over the old one, which provided separate forms of different types and often of different colors for each type of service.

Individual Observation Record

The individual observation record, an 8½- by 11-inch card, is used to record in chronological order data on all types of clinical services given an individual. It replaces the numerous forms previously used for the various clinical services. It contains sections for identifying information; medical history; disease experience; immunization data (for use in well-child conferences); findings, recommendations, and progress notes, by date and type of service; and results of laboratory and other tests, by date and type. Each entry in the narrative portion of this form—the section for findings, recommendations, and progress notes—is signed by the person performing the service.

Other Records

The tuberculosis program register and the orthopedic clinic record used in the earlier system were retained without change in the new system. The former, a visible file, is a modern and useful device for operating a tuberculosis program and is a permanent part of the new record system. The latter must be used until all counties served by the orthopedic clinic adopt the simplified forms.

Supplementary records giving detailed data

are used when needed, particularly in the initiation of special programs. For example, in the nutrition program it is necessary to keep daily records of individual food consumption to determine nutritional patterns. These data are summarized on the family service narrative or on the individual observation record. Other forms, such as the laboratory form which accompanies a blood specimen to the laboratory and on which the laboratory findings are recorded, are destroyed after the results have been posted on the basic record cards, proofread for accuracy, and tabulated for reports.

The Filing System

A simplified system for filing the new service records was also developed. The master cards, which constitute the greatest volume and which are the records most frequently referred to, are filed alphabetically. Guide cards subdivide each group of approximately 25 cards. The cabinet is located beside the receptionist's desk, where the patients are registered, and is accessible to all staff members.

Active family folders containing individual observation records of family members are filed alphabetically in lettersize cabinets behind one-fifth cut guide cards. Alphabet guides are in the first position; guides with family names which occur most frequently or which are withdrawn and refilled most frequently, in the second; the family folder, labels, in the third and fourth; and "out" cards in the fifth. Immediately following the family folders are miscellaneous folders (for each alphabet letter) containing the individual observation records and correspondence for patients for whom there are no family folders.

Inactive records are transferred to an inactive file set up like the active file. Pending files are used from time to time for groups of records withheld for completion of immunizations or for those used routinely in outlying clinics.

The System in Operation

In addition to the development of new forms and a new filing system, the records project included the study of such factors as the floor plan of the building, the position of furniture

Compact, Organized Central Records Room Facilitates Management

Located on the first floor of the health department, the records room, shown in the photograph, contains: (1) master card file; (2) visible file holding tuberculosis case register; (3) intercommunication system box; (4) dumb-

waiter for sending records to the second-floor nurses' office; (5) file for family folders and individual observation records; (6) file for discontinued records; (7) metal case for carrying records to outlying clinics; and (8) file for small and large X-rays. The sketch above shows a nurse in the second-floor office adjacent to the clinic receiving a record sent up in the dumbwaiter from the records room.

and equipment, and the location of lighting fixtures in relation to the flow of records and the routing of patients. As a result of a better understanding of these factors, the staff nurses voluntarily agreed to exchange offices with the receptionist in the interest of greater efficiency. To facilitate the flow of records, a dumbwaiter, designed by the health officer, was installed to carry records from the first-floor file room to the second-floor clinic.

The forms were used on a trial basis for 8 months. A preliminary guide to their use was prepared. During the trial period, staff members kept notes on problems encountered and offered suggestions for using the records more effectively. Periodic conferences were held to evaluate progress and to consider necessary adjustments.

Only a few minor changes were made in the forms, but a number of changes were made in procedure. The transfer of information from old to new forms produced the most difficulty

and placed the heaviest burden on the staff. In May 1951, a manual of instructions incorporating the results of the preceding 8 months' experience was completed. This manual was prepared by the University department of field training.

The successful changeover from the old record system to the new was made possible through the combined efforts of public health workers from the district health department, the School of Public Health, and the State board of health, representing several different public health disciplines.

The results of this project have reached a great many people by various avenues. Students assigned to the health department for field training or for the residency program for medical officers have had an opportunity to see the system in operation. Seminars on records have been conducted for the students of the North Carolina School of Public Health as part of their study programs. The system has been

explained to visitors to the district health department. The district health officer reported on the simplified records at a meeting of the local health officers of the State. Similarly, the nursing supervisor discussed the records with the nursing supervisors of the State at an annual meeting. At the 1952 annual meeting of the Southern Branch of the American Public Health Association during the "curbstone consultation" session, the new system was ex-

plained by the nursing supervisor and by a records consultant from the State board of health. In 1953, experience with the new system was reviewed during a panel discussion on service statistics before the statistical and clerical section of the Southern Branch of the American Public Health Association. Copies of the manual of instructions with copies of the forms have been sent to public health workers in a number of other States and countries.

Kanawha County, West Virginia

Coordinating Medical and Nursing Records

By L. A. DICKERSON, M.D.

THE NEED FOR a revision in the system of records and reports in use in the Kanawha-Charleston (W. Va.) Health Department was brought forcibly to our attention not long after consolidation of city and county units late in 1947. A short time after this merger, the local Visiting Nursing Association moved to affiliate with the official agency and to coordinate its nursing program with the official nursing program. Thus, the personnel, equipment, and records of three agencies were brought together in one location.

Within little more than a year after consolidation of these health units, the number of clinic services had more than doubled, with a corresponding increase in the case load. Spe-

cialized record forms were used for each of the clinic services, and the files were located in four different offices. Since no central index had been maintained, it was often necessary to search the files in each office in order to obtain complete information on patients receiving more than one service.

As a starting point in planning for a revision of the system, a record committee was selected from members of the health department. Included on the committee were the supervisor of nursing, the sanitation director, one clinic nurse, a records clerk, the administrative assistant, and the secretary to the public health director. Consultant help was sought and obtained from the State health department and from the regional office of the Public Health Service. Many meetings were held over a period of several months to decide upon the projected new record forms and procedures. Since provision for a health center was being made in a general hospital then under construction in another part of the city and only the clinic services were to be moved to this location upon its completion, it was decided that no attempt should be made to combine medical and nursing records, but instead to provide for interchange of infor-

Dr. Dickerson is director of the Kanawha-Charleston Health Department, Charleston, W. Va. Prior to coming to Charleston, he served as health officer in Fayette and Boone Counties, W. Va., and as director of the Bureau of Venereal Disease Control, West Virginia State Health Department. At the present time he is also a member of the Governing Council of the American Public Health Association.

mation between the two services. Sanitation records were already centrally located within the sanitation division and were considered to be satisfactorily maintained.

The objectives set forth by the record committee in its approach to the problem were:

1. To centralize in one record all medical information on each patient and to provide for interchange of information between medical and nursing services.

2. To eliminate duplication and unnecessary recordkeeping.

3. To reduce the number of record forms.

4. To establish a routine for followup of service where indicated.

5. To compile reports only on information that would be of use.

Many considerations of a practical nature entered into the thinking of the committee in striving for the attainment of these objectives. A majority of the clinic service records then in use were 5 inches by 8 inches in size but of different designs. A major complaint of personnel using these records had been that the same basic information on a given patient was recorded on several different forms. To meet this objection it was decided that a single form should be devised for recording all medical, social, and economic information needed on the patient, whatever the clinic service.

Clinic physicians had expressed a desire for a form with only a few general headings but with sufficient space for entering rather complete notes covering history, physical findings, and recommendations. Accordingly, a simplified history and physical examination form was prepared.

Three other forms that were considered essential were developed and adopted without disagreement. These provided for recording (1) all public health laboratory tests on a single form, (2) continuing observations and services, and (3) the public health nurse's report to the clinic. Provision was also made on the latter form for supplying information to the public health nurse as to physical findings and recommendations of the clinic physician.

Since an appreciable number of persons visiting the clinics received only screening tests, the need was felt for a form less expensive than

a folder to record miscellaneous services other than services rendered by a physician. This consideration led to the adoption of a form which could serve as an index card and could also be used to record such miscellaneous services as laboratory tests, immunizations, and chest X-rays.

In order to utilize filing equipment then on hand and to make it possible to interfile old service records with the index cards, it was decided that this form should be 5 inches by 8 inches in size.

Forms and Rules for Use

The record forms that were finally adopted and the general rules for their use are as follows:

Index card. This card is completed for each person visiting the health center for service. A number is assigned to each individual at the time of the first visit, to be retained for all subsequent visits. For all patients not examined by a physician in one of the clinics, this will be the only service record.

Record folder. A lettersize manila folder containing the necessary basic forms is prepared for each individual to be seen by a physician in one of the clinics. A distinctive color tab is affixed to the folder to denote the clinic service. The individual's number, obtained from the index card, is entered in the upper right-hand corner of the record. Each folder has a pocket inside of the back cover to hold odd-sized, old record forms.

Forms Included in Record Folder

Five basic forms are included in the record folder:

Basic data form. This form provides space for recording all necessary basic information on the patient and members of his immediate family. It is completed for each individual at the time a record folder is initiated. When more than 1 member of a family visits the health center at 1 time, detailed information concerning the family is recorded for 1 member only and a reference note made on the records of the others.

Medical sheet. Pertinent history, physical findings, and recommendations are entered on

this sheet by the examining physician for all public health clinic services except tuberculosis, for which there is a special form. A few outpatient clinics require a special form in addition to the medical sheet and the tuberculosis form.

Laboratory report form. All laboratory reports are entered on this form except when laboratory tests are performed in the hospital laboratory. In the latter instance the original report is included in the record folder. Chest X-ray readings are sound recorded and transcribed directly to the laboratory report form.

Progress notes. This sheet is used by all workers in the health center to record their observations on or services to a patient. Social service and mental hygiene clinic workers record only a summary of their findings and recommendations on this form and keep a separate file of detailed case studies.

Nurse's report to clinic. This form is completed and sent to the health center for all individuals referred to the clinic by the public health nurse. It is also used to inform the public health nurse of the clinician's findings and recommendations for home care. When used for the latter purpose it is retained in the nursing record.

The basic data and progress notes sheets are stapled to the left inner side of the folder, with the basic data underneath. Staples are used here for economy, to reduce bulk, and also because there is usually no necessity to remove these forms from the folder.

On the right side of the folder a binder holds the remaining record forms in place in the following order from the top: medical sheet, nurse's report to clinic, correspondence, laboratory reports.

Appointment cards, tickler files for followup, and clinic route slips are also prepared. The route slip is attached to the record folder and serves to indicate the services to be received by the patient.

Changing to the New Record System

The date for changing from the old to the new system was set to be effective when clinic services were activated in the new health center.

Since the tuberculosis case load was one of

the highest, it was decided to use the active register of these patients as a basis for converting old records to the new system. About 6 weeks prior to the proposed date of the change, an additional records clerk was employed on a temporary basis. This clerk reviewed the tuberculosis records and prepared a new folder for each active case, filing the old clinic record forms in the pocket inside the back cover of the manila folder. Each patient was assigned a permanent clinic number. Other clinic files in the department were searched for each patient whose record was transferred into the new system and, when other records of service to these patients were found, the various-sized old record forms were included in the pocket of the folder. No attempt was made to transfer detailed information from the old to the new forms.

The process of combining all records on active tuberculosis cases and entering them in the new record folders before moving to the health center constituted a trial period with the new system. This enabled us to make many adjustments in record procedures which contributed materially to smoothness of operation when the system later became effective for all service records.

Clinic equipment, personnel, and records were transferred to the new location, all services were discontinued for 3 days, and all active clinic records were moved into a central records office in the public health wing of the hospital. When operation was begun in the new location, all patients coming in for clinic services had records instituted in accordance with the new system.

As had been expected, several problems were encountered during the period of transition. However, most of these problems were minor in nature and were concerned with the routing of patients and flow of work. Somewhat detailed rules for use of the new records had been developed prior to their adoption, and these had been discussed in frequent conferences with all personnel using the record forms. Although an additional experienced clerk had been appointed for a 2-month period, the burden thrown on the chief records clerk was exceptionally heavy during the trial period when active tuberculosis records were being

converted into the new system. It was gratifying, however, to note that after a short period of experience, less time was required on the part of all concerned in maintaining the system. It has not been necessary to employ additional record personnel, although the case load remains at essentially the same level as it was prior to the institution of the new system.

With the exception of 6 lettersize filing cabinets, no major new equipment items were required.

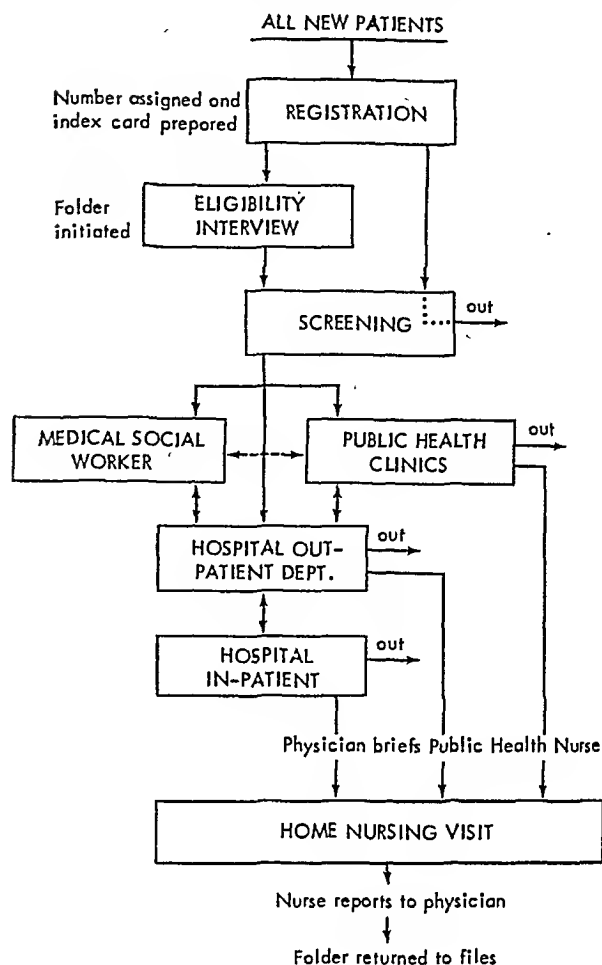

Cross-Referral of Records

Several months after the new record system was instituted, outpatient clinic services were established by the hospital in a separate wing. By agreement with hospital authorities, all new patients reporting for outpatient services are interviewed by health unit personnel and a decision made as to their eligibility for such services. Thus, the records for patients visiting the hospital outpatient department are initiated in the health center as well as those for patients visiting strictly public health clinics.

After registration, all new patients routinely have blood specimens drawn for a serologic test for syphilis and for dextrose determination and receive a chest X-ray. Those patients who are to visit an outpatient clinic are then escorted with their records to the outpatient department of the hospital. These records remain in the outpatient department, are filed there, and their location is shown on the health department index card. If a patient is referred back to one of the public health clinics, his record is requested from the outpatient department of the hospital and its whereabouts shown by an "out" card placed in the outpatient department file.

When a patient is transferred from one of the clinics into the hospital, a transfer form is executed and, in addition, the outpatient clinic record and/or public health clinic record is incorporated into the hospital record folder. Upon discharge from the hospital, patients who are referred for clinic service have their records made available to the outpatient department. When home nursing visits are requested, the nurse's report to clinic form is completed by the physician requesting the visit, and this form is retained in the individual's record of

Flow of patients and records, Kanawha-Charleston Health Department.

"Out" indicates home visit not necessary

nursing service. After making the home visit, the public health nurse uses this form to report to the clinic physician the observations made and services rendered. This report is then included in the clinic service record. The chart illustrates the flow of patients and records through the health department clinics and the hospital.

Since an index to the records of all clinic patients is kept in the public health unit, it has not been considered necessary to have a record index in the outpatient department of the hospital.

Tabulating Reports

In conjunction with the adoption of new record forms and procedures, a report form to be used as a daily work sheet was developed.

This form calls for a minimum amount of information on service provided the individual and on place of residence and is intended primarily for the information of local appropriating bodies. Certain additional information is compiled for maternal and child health and communicable disease services to be forwarded to the State health department. Reports are summarized once monthly. It is the belief of the Kanawha-Charleston Health Department that with this system professional personnel can obtain adequate additional information by an annual case-record review and by sample studies as the need arises.

Factors facilitating such reviews or studies are:

1. The distinctive color tab affixed to the folder to denote the clinic service or services which permits ready selection of records.

2. All services received by the individual complete in one folder or, if there is no folder, on one card.

3. Simplification of forms and reduction in their number, which reduces the task of extracting needed information.

Comment

Not long after the institution of this record system its advantages became apparent. Almost immediately satisfaction was evinced by all personnel concerned with medical and nursing records. In the 18 months that the new forms and procedures have been in use only minor changes have been necessary. Thus far no serious disadvantages have been found. One of the most important advantages noted is that the complete record accompanies the individual as he or she is routed for various clinic services. As a result, the work flow is smoother and the patient is served more effectively in less time than was possible with the old record forms and procedures. It is true that the index card has proved to be somewhat larger than necessary to record the required information on a substantial number of the patients reporting for service. However, this objection would seem to be outweighed by the advantage of being able to interfile index cards and old records of the same size.

Reexamining Health Record Forms

By EDWARD W. COLBY, M.D., M.P.H.

RECORDS AND STATISTICS go hand in hand, but since records are the source of statistics, they are basic. If these basic records lack in quality, the conclusions drawn from them will be that much less valuable.

But however anxious we are to have usable records and the statistical data derived from them, to a goodly number the recording of information is a chore to be avoided. Why? Lack of time? Yes, to some extent. Lack of interest? Undoubtedly. Too much detail may require too much effort or the recordkeeper

may discern no useful purpose for the information. Recording of information and data, unless carefully tended, may easily become merely a matter of habit. Like garbage, record procedures and forms must be reviewed and removed often to keep them from becoming obnoxious.

Change in Emphasis

It is generally agreed that records should be maintained for the purposes of: (a) providing the best possible service to individuals and fam-

ities; (b) program planning; (c) more efficient program operation; and (d) program evaluation. In too many instances, however, records are maintained for justification—the accounting for time or the accumulation of impressive figures. The perpetuation of this fault cannot be blamed solely upon those in the profession. It must be shared by those to whom we may be responsible—the public at large, mayors, managers, councils, and boards.

To change this superficial approach to record-keeping, the health department must, perhaps, present public health to these groups in more solid and understandable terms, concentrating upon the substance from which these data are derived.

Many lengthy discussions have taken place as to how to record and account for certain activities. Consider nursing visits, for example. To the individual, family, and community served by the visit, the activity may be of major importance, as in the instance of an initial followup visit to a tuberculosis suspect. Yet when that particular visit is cumulated as a part of total “nursing visits” in an annual report, it becomes just another numeral and has no particular significance to the community.

How much would be lost if we discontinued accounting for such items as number of nursing home visits and substituted the number of nursing hours devoted to home visits, to school or clinic service, or to other special activities? This information, when related to the numbers of individuals served, would be of much greater significance to everyone. True, a long chain of precedence would be broken, for never again would that particular service be able to make a comparison with another agency on an annual basis of numbers of nursing visits alone. (If for some particular reason the number of visits

were necessary, sampling would provide these data.) Are nurses employed for the number of visits they are to make or are they employed to give a certain number of hours of service per week? The answer is obviously the latter, and it is the only basis, particularly in a generalized service, upon which performance accounting is at all valid.

Standardization

Despite many statements to the effect that “standardization of forms and records is not possible because of the variation in program emphasis from one community to another,” it is my personal contention that appreciable standardization is possible. The principles of public health are basically the same the country over, and in spite of varied emphasis standardized record forms could be used to considerable advantage. Perhaps the difficulty involves not only standardization of record forms but also the companion need of uniform nomenclature. More uniformity is possible. Witness the increasing acceptance of the Public Health Service recommended eating establishment and milk ordinances and codes, the national plumbing codes, and many of the service records relating to these. To some extent standardization has been accomplished in certain nursing records. The Public Health Service has promoted a certain degree of uniformity in tuberculosis and venereal disease service records, but much more can be accomplished in this respect.

Nearly 20 years ago the American Public Health Association's Committee on Administrative Practice named a Subcommittee on Record Forms whose “purpose was to encourage the development of a satisfactory system of records for city health work.” The workable forms drafted by the committee were edited by Walker and Randolph and published under the title of “Recording of Local Health Work.” That volume outlined basic principles concerning forms and records applicable to the programs of that day, and it has remained about the most complete reference on the subject.

A valuable aid to many local health departments, small or large, would be a central reference source from which could be obtained sample records manuals with forms and informa-

Dr. Colby has been health director of the Portland City Health Department in Maine since 1950. Previously he was director of the division of communicable disease control of the New Hampshire State Department of Health. Dr. Colby received his medical degree from the Albany Medical School in 1939 and his master of public health degree from the Harvard School of Public Health in 1947.

tion regarding types of records systems. Many commercial distributors of business forms and methods seem to be of little assistance in adapting their systems to the needs of public health, although it would seem a simple matter to devise stock forms for public health similar to those available for private physician, dentist, and hospital records.

Records in Portland

The Portland health department's concern with a review of its records and records procedures began approximately 3 years ago, with a reorganization of the department. Most of the record forms of the department had been in use for an extended time. In many of them, items were being recorded as a matter of course without any particular knowledge of how the information could be used. Reasons for this were evident. The staff had not been indoctrinated in the use of the particular forms; it did not have the benefit of periodic review of forms, and no forms-use manuals existed.

For the two reasons, economy of staff time (work simplification) and to obtain more meaningful statistics for program planning and community education, a records review was undertaken. Because of the magnitude of the problem, it was decided to concentrate upon nursing and medical service records as the first step. A short-term loan of a Public Health Service records consultant was obtained to advise and assist. Following the basic step of a general study of the record forms procedures and files, a staff committee was appointed, and all proposals were discussed with the committee at frequent intervals. This procedure served not only to reconcile differences of opinion, but also served as inservice training.

Procedural Revisions

A summarization of accomplishments illustrates the value of such a study. Much time and effort have been saved by procedural revisions: transfer of certain phases of the recordkeeping process from nurse to clerk; rerouting the flow of records; redesign of work sheets and cumulative reports; and joint participation of clerk and nurses in certain preclinic records preparation. As an example, it was estimated that

formerly at least 8 percent of the total staff nursing time, the equivalent of one nurse's time, was used in the keeping of other than service records. The time now required has been reduced to but a small portion of the previous figure. The elimination of miscellaneous registers containing information on record elsewhere was in itself a timesaver.

As planned, this study is only one step toward an eventual complete overhaul of records which will result in even greater economies of time and the accumulation of more valuable statistics. Long-range planning anticipates the use of mechanical tabulating procedures such as "mark-sense" records. These will enable the health department to accumulate administrative and service statistics with a minimum of extra effort. To this end, the department's basic record review and simplification process is an essential interim step. Many of the resulting records are intentionally designed for temporary trial and error use before final adaptation to mechanical tabulation forms.

The benefit of procedural revision was clearly demonstrated after a system of hand-sort punch cards was installed for recording and analyzing vital statistics. Prior to its use approximately 2 months were required to assemble and tabulate data for the annual report. It now takes approximately 2 weeks for the same procedure.

Single Immunization Record

A single immunization record was developed which permanently records the parent's signature giving consent for both primary immunization and "booster" doses. This same record also provides for an individual's chronologic history of all immunizations. This one card replaces at least three record forms maintained for separate immunization procedures. In arranging for school immunization clinics, this record avoids the further necessity of preparing and sending home to parents separate consent slips when "booster" shots fall due.

Besides saving the costs of the several different immunization forms and consent slips and the time spent in processing all of these, this innovation also eliminated three separate immunization registers. Information recorded in these latter was actually a duplication of data already recorded on separate cards.

New Immunization Record Card

Master-Location File

The establishment of a so-called master-location file within the sanitation unit combined records housed in many separate files. This is a general resource file for information on premises, other than those of special classification (restaurants, bakeries, and pasteurization plants). In this file, in individual 8½- by 11-inch folders arranged alphabetically by streets and street numbers, are kept all records and correspondence pertaining to a particular address, housing sanitation original inspection reports, the resultant orders issued, exchange information from fire, electrical, building, public works, and other departments. These folders contain extensive chronologic histories and, to avoid loss of papers, since they are used by several persons, a patented "corner clip" affixed to the folder binds them in place, yet makes removal and insertion a simple matter. This combination has eliminated a number of different sized card and record file cabinets and the consequent

number of places to search for information. It takes no imagination to realize the savings in time and patience resulting from the use of this centralized-file procedure.

Within the current year the city of Portland has been officially divided into census tracts for the first time. Henceforth, the health department will be able to relate sanitation and nursing services to population and environment, the more effectively to evaluate service as well as to plan future program requirements.

To those who may be concerned with the development and use of records, these simple suggestions are made:

1. Plan carefully.
2. Design simply.
3. Pretest if possible.
4. Seek assistance from practical consultants.
5. Make friends with a good printer.
6. Develop a forms-use guide.
7. Review periodically and revise when indicated.

Curbstone

Consultation:

An Effort

To Improve Communications At Annual Meetings

I. Origins of the APHA Southern Branch Experiment

By BEN FREEDMAN, M.D., M.P.H.

AS PROFESSIONAL associations have grown in size and numbers, annual meetings in particular have become more diversified and cumbersome. In the initial stages of the development of public health associations, only a small handful of enthusiasts participated. Such small and highly motivated groups had no need to be unusually concerned about methods and techniques of holding meetings.

Tradition, however, has a way of stabilizing procedures, and financial considerations are a powerful force in channeling the course of

activity. These can shackle forward movement, unless, of course, the tradition be itself in essence a conscious effort to innovate, to accept, and to adapt to change, and unless we become masters of our financial problems rather than finances becoming the master of our methods. In public health, tradition has been of a very plastic character in relation to the science of hygiene, less so in relation to the art of group dynamics. Thus, the scientific content of our annual meetings has continued to grow while the efforts to get this information to attending members have been much less fruitful.

To a large extent, this has been true because of the compulsion for getting "papers" presented and published, even though many of the papers be merely restatements of already established information and themes. This tradition has continued to grow, and the limited outlet for publication has created a bottleneck and a dilemma. And yet, there is as important a place for the presentation of elementary information as for the new without perpetuating the pressure of publishing such presentations. This is especially true for new public health workers and for the partly experienced and un-ripened field workers who are in the process of learning that which the experienced health worker has already crystallized into his store of knowledge. It is the kind of information which is best disseminated through consultation and discussion.

Dr. Freedman is director of the public health training center of the Louisiana State Department of Health and assistant professor of public health administration, department of tropical medicine and public health, Tulane University Medical School. He has taken a leading part in the activities of the Southern Branch of the American Public Health Association since 1946, as program chairman, as secretary-treasurer, as president (1950-51), and as a member of the executive committee in 1952-53.

It is our task to make a place in our annual meetings for restatement of the older and established information for those who need it without encumbering the already seasoned health workers who are seeking what is new. There are, of course, exceptional circumstances when exceptional individuals may present interpretations of old ideas in a new and enriching manner.

What is needed, then, is not fewer meetings but a better adjustment of the dynamics of holding meetings patterned to the purposes for which particular meetings are held.

The Needs of Field Workers

The Southern Branch of the American Public Health Association has centered its interest primarily on the public health field worker. It has, therefore, been incumbent on the Southern Branch to devise methods of holding meetings which would best serve the field workers, and which would make the annual professional meetings both opportunities for the active participation of most of those who attend and profitable public health experiences for those who participate.

The purpose of annual meetings should coincide with the interests and needs of those for whom the meetings are held. For the majority of public health field workers, the most common reasons for going to meetings could be classified as follows:

The need that professional workers have for talking over their problems and sharing their local successes with colleagues from other localities and with recognized specialists and authorities.

The mental and emotional stimulation they get in anticipating the atmosphere of good fellowship and in experiencing the unexpected—effects which are reflected in performance on the job.

The need of individuals to expand their sphere of participation in the activities and achievements of public health work, particularly to participate actively in professional meetings in order to satisfy their ego, to widen

their sphere of acquaintance, to develop a broadened viewpoint, to accumulate experiences, to learn new trends—all of which develop confidence and build competence.

The feeling that they will gain a better perspective of their specialty in relation to the total public health picture, and the need to feel part of a larger community of interests to which a portion of one's life has been dedicated.

If the majority of public health field workers go to annual meetings for at least some of the above purposes, then the planning, the organization, and the operation of the meetings will require a more dynamic approach. All, or most, of the expectations of the membership necessarily must be satisfied and members must be stimulated and helped to meet in productive manner for discussion of their problems.

The First Curbstone Attempt

No one in a professional field is unaware of the inherent vitality of the annual meeting or of its shortcomings. A large assembly is more often than not charged with the atmosphere of hide-and-seek, despite the fact that much which is there is valuable and useful. In such an atmosphere in 1950 was born the idea of "curbstone" consultation. Could not public health consultants man booths similar to the commercial displays and exhibits seen at many association meetings? Could not they exchange information there with their colleagues who seek a heart-to-heart discussion of the routine problems which the formal presentation of papers seems not to touch?

The idea caught on. Some weeks later it was adopted by the program planning committee of the Southern Branch for its 1951 meeting in Biloxi, Miss.

The informal designation of curbstone consultation was used to describe this approach, with the hope that the informality of the method would secure flexibility and adaptability. Since a start had to be made, the Biloxi meeting was geared to the following plan:

A list of 50 public health subjects thought to be of interest to field workers to be selected and classified in accordance with the major interests of the various sections of the parent American Public Health Association.

In the same manner as scientific and commercial exhibits operate, each subject or group of subjects to have a booth; those representing subjects relating to a particular section to be arranged in proximity.

Each section chairman to be responsible for obtaining enough consultants to operate each booth. Depending on the nature of the subject matter, there should be enough consultants for each booth so as not to tie down any consultant over too long a period, since each one would probably also have need for seeking consultation.

Consultants for each booth to develop their own method of operation, being responsible for bringing their own visual aid materials, technical demonstrations, or printed matter.

Each booth to have at least one table and several chairs and to be supplied with a registration book.

Each section chairman to be responsible for having placards made for each of his section booths, indicating the names of the consultants serving each booth at a particular time.

An overseer or manager for each booth to be designated from among the consultants who would meet for a short time before the curbstone session in order to plan such administrative details as the sequence in which the consultants would take their place in the booths.

Out of a 2½-day meeting, a full day to be devoted to curbstone consultation.

This plan, of course, was designed to meet the general needs of field workers. Specifically, it was hoped it would—

Give broad participation to field workers.

Give firsthand personal contact between Association members from different States in an organized, orderly, and expeditious manner.

Give a real opportunity for exchange of ideas and personality impressions.

Bring the timid more easily into participation.

Provide a better opportunity for general and specialized information exchange.

Make most people feel their importance in the community of health workers.

Breed confidence in those who might feel themselves lacking in the opportunity for broadened contacts.

Bring together on a favorable basis those who have had the opportunity to contribute to public health with those who are becoming the future contributors.

Bring into more favorable light those who deserve recognition.

Stimulate those who were chosen as consultants to organize their knowledge about their subjects and to develop their abilities to impart their knowledge to others.

The Plan in Operation

The section chairmen were key figures in developing the modus operandi of this first attempt at curbstone consultation. They were supplied with an outline detailing their responsibilities and those of consultants and booth managers and setting forth some of the details of arrangements. Consultants were urged to get at the preparation of materials as early as possible. Special attention was given to materials to be used in the consultation process. The following were specifically suggested:

Articles, pamphlets, outline notes, worksheets, and the like, which describe new methods of approach to problems, new techniques, means of evaluating programs, and any other tools which could be of practical use to the field worker.

Placards carrying provocative questions concerning practical field problems.

Technical demonstrations that would be interesting and informative to the membership.

Audiovisual materials for demonstrating aspects of work which could be adapted by field workers.

Section chairmen were advised further that an announcement would be made at the first general session of the meeting describing the purpose of curbstone consultation and how it

would operate. Consultation periods were scheduled for an afternoon and for the following morning.

Naturally, there was some misunderstanding and apprehension on the part of those making the arrangements and of the consultants. Even the essentially mechanical matter of arranging the booths to the satisfaction of the consultants was not easy. Some booth spaces were too small and too far removed from the flow of traffic. Signs and placards were not all ready and satisfactory. Some booths were spaced too closely, and others lacked needed equipment and facilities. The commercial booths were separated from the consultant booths and were located conspicuously away from the flow of traffic. Some booths had to be dismantled too early in order to prepare for other activities. Nevertheless, the crowds that attended the booths were encouraging, and most individuals who were not concerned with the operations appeared to be having a refreshing experience.

Lessons From Biloxi

No plan for evaluating the curbside consultation part of the program had been set up. However, every section chairman and consultant was asked for observations that would contribute to better planning in the future. Many other individuals were asked for similar pertinent criticism. Much was gleaned from this unorganized method of evaluation; and, indeed, many flaws in the method of organizing the program were brought to light. However, with few exceptions the response was enthusiastic and exciting. Most individuals were convinced that this method or a similar dynamic organization, when developed more smoothly, would definitely meet the needs of the field workers.

A meeting was called several weeks after the Biloxi meeting to evaluate the criticism and to make recommendations to those who were to organize the next Southern Branch meeting in the spring of 1952 at Baltimore. Recommendations dealt both with the general approach and with details of administration. It was suggested, for example, that 2 half days be devoted to curbside consultation on the second day of

the meeting. Planning, it was thought, should be handled by a chairman and committee, and the planning phase should be extended. Also, more advance information about the plan should be made available, including names of consultants and their topics and schedules. Southern Branch members should be briefed at section meetings prior to the consultation day. If possible, section meetings should be tied in with consultation in such a way that questions remaining unanswered could be referred to the proper consultation booth. The membership also should be informed of their own responsibilities as well as of the personal advantages to them in participating in the consultation process; that is, they should be prepared to raise questions and discuss their own problems and experiences.

It seemed sensible to reduce the number of consultation booths or topics to a relatively few functional and subject-matter categories, each precisely defined. Consultants should be asked to make an effort to find out as much as possible about each other's topics so that useful referrals could be made, should spend at least 2 hours on duty, and should report to the chairman their experiences and suggestions for further development.

As for physical arrangements, temperature, ventilation, and lighting were found to be important. Booths should be easy to locate, well marked, attractively arranged to permit a degree of privacy in consultation. The booths should be set up before, not during, the meeting. They should be stationary and not subject to interference from other activities. Commercial and scientific exhibits should be placed in the same general area, or at least in the stream of traffic, and exhibit materials and means of posting signs and displays should be provided.

Although the recommendations resulting from the evaluation of the Biloxi meeting supplied a few new items which were adopted for the 1952 Baltimore meeting, the new circumstances of the latter meeting brought forth new ideas and new experiences which were quite unexpected and exciting, thus underscoring again that flexibility and adaptability are the essence of the curbside consultation technique.

II. Three Years' Experience With Curbstone Consultation

By WILLIAM P. RICHARDSON, M.D., M.P.H.

ALTHOUGH there have been many criticisms and suggestions with respect to details of plans and arrangements, there has been universal and enthusiastic approval, by all who have participated, of the "curbstone" consultation technique pioneered by the Southern Branch of the American Public Health Association since 1951. Some of its advantages are immediately apparent. These, and the history and philosophy of the idea, have been well stated by Freedman in the preceding report.

This discussion is devoted to an analysis of experience at the three meetings where curbstone consultation has been used—Biloxi, 1951; Baltimore, 1952; and Atlanta, 1953. Because the technique was new, a deliberate effort has been made to try different methods of organization, and it is believed that sufficient experience has been gained to provide some guidance to those who may wish to consider its use.

Perhaps the most difficult problem in developing a curbstone consultation program is that of physical facilities. The original concept was that spaces or booths similar to those used for commercial and scientific exhibits should be provided. While this concept has value so far as the general plan of arrangement is concerned, it was soon apparent that the spaces needed to be much larger than conventional booths. The consultation often assumed the form of a roundtable or group discussion involving 10 to 20 or more people, so the area provided had to be sufficient to seat that number.

Seriously complicating the problem of space

and arrangements is the fact that few hotels or auditoriums have sufficient available space to provide for curbstone booths in addition to the usual commercial and scientific exhibits and general and sectional meeting places. Thus, it becomes necessary to set up booths in areas used at other periods for regular meetings. The time required for conversion must be considered in planning the schedule. The provision of stands, screens, or curtains for separating the spaces may also create difficulties, and it is essential that this need be anticipated and arrangements to meet it be made well in advance.

It has been the experience of the Southern Branch that ideal or even nearly ideal arrangements cannot be expected, but with careful planning, arrangements that are reasonably satisfactory can usually be worked out. A decision that sometimes must be made is whether to use some very satisfactory individual spaces which may be available at considerable distance from the main area. In our experience it has proved better to group the booths in the same general area, even though by so doing some of them will not be quite so satisfactory in space and appointments, because isolation is a severe handicap.

The period devoted to the curbstone consultation program also provides a splendid opportunity to visit the various exhibits, and to this end it is helpful if the curbstone area is fairly close to the exhibit areas.

The most satisfactory arrangement worked out has been to set up 2 rows of booths in a large meeting hall or ballroom, separated by heavy curtains or screens, preferably 6 feet high, providing space of approximately 12 by 14 to 14 by 16 feet. If it is anticipated that most booths will not have more than 8 or 10 participants at a time, the size of the spaces may be reduced somewhat and provision made for the availability of 2 or 3 rooms capable of accommodating 25 or 30 people to which groups which outgrow the booths can be moved. It is preferable that the booths not be too small, however, because size helps to mitigate noise interference and foster the illusion of privacy. Basic equipment needed is a table, chairs for the consultants, 15 or 20 chairs for those seeking consultation, and a sign indicating the consultation

Dr. Richardson is professor of preventive medicine and assistant dean for continuation education, University of North Carolina School of Medicine. He was curbstone consultation chairman in 1952 and general program chairman in 1953 for the Southern Branch of the American Public Health Association.

topic. The sign is most advantageously displayed on a small stand or easel.

Patterns of Scheduling

The Southern Branch meetings are of 2½ days' duration. We have experimented with both the time relationship of the consultations to other features of the program and with the plan of scheduling subjects and consultants. At the Biloxi meeting in 1951, where the curbstone feature was first introduced, the consultation period was scheduled on the first afternoon after a morning general session, and again on the second morning, followed in the afternoon by section meetings. At the 2 subsequent annual meetings, it was scheduled from 9 a. m. to 3 p. m. on the second day. No other technical sessions were scheduled for the day, and no recreational activities were planned until after 3 o'clock. This second schedule worked somewhat better than the one at Biloxi. However, the suggestion has been made, and probably will be incorporated into the plan for another year, that it would be helpful to have a general session, perhaps 1½ hours in length, on the morning preceding the curbstone program. With the day's program consisting of only the informal consultation feature, many people tend to get scattered. Having a brief formal session of general interest first might counteract this.

Another significant factor to be considered in planning the schedule is the form the consultations are expected to take. The original concept was almost exclusively in terms of a single individual seeking advice and assistance in regard to his particular problems.

In practice, the process has more frequently turned into group discussions involving a number of individuals. These have proved to be popular and most worthwhile, but there has been the complaint that they did not allow the opportunity for desired individual consultation. This problem has not yet been solved. For the next annual meeting, it is proposed to divide the consultation time into 2 periods of perhaps 2 hours each. During the first 2 hours, there would be general consultation, usually on a group basis. During the second 2 hours, there would be individual consultation by appointment only. Appointments could be made for

15-minute periods by signing a sheet available at the booth or at the registration desk during the first 2-hour period.

Topics and Consultants

For the Biloxi meeting, a list of general topics was compiled, and each section chairman assumed responsibility for getting consultants for the group of topics which fell within the area of interest of his section. In general, one consultant was selected for each topic, and he was delegated to get other consultants. As a result, many of the more widely known workers in the region were asked to participate in consultation on as many as 6 or 8 topics, and there was much confusion. For the past 2 meetings, detailed planning has been concentrated in a small committee and has actually been handled largely by the chairman. This has thrown a heavy burden on this one individual, but it has made for much more effective coordination and balance.

Under this procedure, section chairmen made specific suggestions as to consultants and subjects, and the committee canvassed association officers and other public health leaders in the various States for additional suggestions. The committee then worked out a tentative list of subjects and consultants, and either issued invitations to the proposed consultants directly, or asked the section chairmen to assume this responsibility for specific individuals. In some instances, section chairmen have assumed responsibility for obtaining consultants on specific subjects, but the chairman of the curbstone committee has received copies of all correspondence so that conflicting invitations or misunderstandings were avoided.

Experience has led us to favor considerable flexibility as to selection of subjects. At the Biloxi meeting, topics were quite general and broad; for example, "local public health nurses," "venereal diseases," "maternal and child health." At the Baltimore meeting, much more specific topics were selected. Many of these were further broken down into three sub-topics, each of which was scheduled for a 2-hour period and was covered by a team of 2 or 3 consultants. At the 1953 meeting in Atlanta, the topics were both general and specific, and teams of 6 or 8 consultants were assigned to each booth

for the day. It was left to a designated booth chairman to work out a schedule which would keep at least 2 consultants at a time on duty without imposing too long a period of service on any individual. This latter plan seems preferable.

The number of topics is determined not only by the need for covering subjects considered to be of widespread interest but also by the space which may be available. In most places where meetings with a membership the size of the Southern Branch (under 1,000) are held, it is unlikely that available space will accommodate more than 18 or 20 booths. Such limitation on numbers requires careful selection of topics. One device which has been of value is to frame the subjects so they will be of interest to several professional categories of people, and to have each category represented on the consultant team.

With respect to selection of topics and consultants, it is advantageous to use both recognized authorities who will be consulted because of their reputation, regardless of the assigned subject, and workers who may be relatively unknown but who have developed a successful program, activity, or technique about which others would like to know. In general, it enhances interest if it is known that a consultant has been selected because of special achievement or competence in the area of the consultation topic. One important source of consultants, of course, is the participants in the general and section programs.

Another factor with which we have experimented is that of displays and exhibits. Originally, all the emphasis was on consultation, and eye-catching exhibits were not encouraged. We have come to the conclusion, however, that here again it is well to allow considerable flexibility and to leave to the judgment of the consultants whether displays or exhibits, or even slides or films, may contribute to the consultation function. A measure of variety makes the program of greater overall interest and attractiveness, provided the fundamental concept of consultation is kept in mind.

Instructing Consultants and Participants

There are several specific details of planning which are important to assure understanding

and smooth functioning. One of these is the provision of a sheet of information and instruction for prospective consultants. Many who are asked to participate will be relatively unfamiliar with this kind of program, and it is helpful for them to receive, at the time of invitation, a sheet describing the program, its purposes and general method of operation, the facilities which will be available, and exactly what is expected of consultants.

This information should be followed by a meeting, which has been scheduled in advance and included in the printed program, of the consultants and the section chairmen with the curbstone consultation committee. At this meeting, last-minute instructions can be given, final details as to plans and arrangements explained, and an opportunity to clarify specific points provided.

An important part of the success of the program depends on intelligent participation by those desiring consultation. To this end, a brief description of the plan is included in the printed program, and the curbstone chairman is given an opportunity at the first general session to explain the process and make any last-minute announcements. In addition, a 2-page mimeographed folder has been distributed, giving somewhat more detailed description of the process, specific arrangements for the current meeting, and suggestions for getting the most benefit from the consultations. Specially designed evaluation sheets or questionnaires are also distributed to provide a systematic means of getting reactions to various aspects of planning and arrangements and suggestions for improvement. These evaluation sheets have furnished many of the ideas which form the basis for changes and improvements from year to year.

Enthusiasm for Program

The membership of the Southern Branch seems enthusiastic about the program innovation of curbstone consultations. Plans are to make them a continuing feature of the annual meetings, modifying and developing details of plan and procedure from year to year as experience may indicate. There have been rough spots, as would be expected with so new an undertaking, but these have been minor in comparison with the interest the programs have

stimulated and the growing evidence of their utility.

The curbstone plan appears to work well for professional meetings the size of the Southern Branch, but it may not be feasible for meetings of larger size. For larger meetings, it could, of course, be used as a feature concurrent with other program features, provided that satisfactory space and arrangements are available.

Success with the program depends on comprehensive planning and careful attention to

the details. It is hoped that other organizations will try the curbstone consultation plan, experiment with various ways of doing it, and make their experiences available to other professional groups. There is strong conviction that this innovation has a significant contribution to make to meetings such as those of the Southern Branch, but continuing experimentation is needed to determine the most effective techniques and to define more exactly the methods, limitations, and usefulness.

each month in

The Partnership in Dental Health

By NELSON A. ROCKEFELLER

WHEN the Department of Health, Education, and Welfare officially came into existence last April 11, it lifted the vital health, education, and social welfare functions of the Federal Government to Cabinet rank. For the first time in our national history, these social responsibilities are represented at the highest council tables of our Government. Health, education, and social welfare have become an integral part of the considerations of the President's official family.

I think this is a logical outgrowth of President Eisenhower's beliefs which center around deeply held convictions concerning the dignity and worth of the individual. His actions in the field of social welfare are a striking example of this humanitarian philosophy.

To him, as to all of us, the problems of peace and war, of international freedom and stability, come first; for there is no individuality for Americans who are threatened by war or tyranny. Next are economic stability and growth at home—the ingredients without which individual growth is impossible. These are the cornerstones of President Eisenhower's foreign and domestic policies—freedom and peace on the international front, and economic stability and growth on the domestic front.

Mr. Rockefeller is Undersecretary of Health, Education, and Welfare. He presented this address, here somewhat condensed, before the 94th annual meeting of the American Dental Association at Cleveland, Ohio, September 29, 1953.

But there is a third element, an element which is encompassed in the broadest meaning of the term, "social welfare." The President has shown in his deep awareness of the fact that all three are inseparably formed together in a free society. The individual develops to his fullest capacity as a member of society only with the background of the best possible educational training. He must enjoy good health—physically and mentally. He must be secure in the knowledge of his protection in the event of extreme hardship, disability, and old age.

The Common Goal

In the field of dentistry and related subjects, the interests of the Department of Health, Education, and Welfare and of the American Dental Association touch at many points. The Department works with many professional associations toward the common goal—better health for each of our citizens. The Department works, of course, in different ways, using different resources and under different patterns of authority. But the objectives are shared objectives and many of the problems are mutual ones.

The Department, as you know, recognizes dental health as a matter of tremendous national importance. We are aware of the many complex and interrelated factors involved—manpower shortages, inadequate appreciation of the significance of dental health, the staggering backlog of accumulated dental needs, and economic barriers to dental care and services.

In this community of interests it is possible

to identify at least three sets of problems which are matters of immediate concern to the dental profession as well as to Government.

First, and perhaps foremost, is the problem of dental education and the needs of dental schools.

Secondly, there is the need for research in the various aspects of dentistry.

Finally, there are the problems involved in the application of scientific knowledge. In other words how can we make sure, within the framework of American principles of free choice, that the benefits of modern research and modern resources reach the majority of the people?

Before considering each of these issues in greater detail, it might be well to redefine the dental health responsibilities which are vested in the Federal Government. The Department operates under laws passed by the United States Congress. This is a basic fact too often misunderstood by the health experts and the public with whom the Department cooperates. As a Federal agency, the Department can do only what the law authorizes. A voluntary or professional health organization, as well as the private practitioner, can do anything the law—and their code of ethics—does not forbid. The distinction is an extremely important one and must be understood to appreciate the interactions of government and private agencies.

Most public dental health services today are provided by local governments. Federal responsibility is limited to research and experimentation, consultation, demonstrations, and, in some instances, to financial participation through research grants and through grants-in-aid to the States and local communities. Through these grants the Public Health Service and the Children's Bureau assist in the development and support of State and local dental health programs. The grants are administered by the localities according to their own needs and patterns. In theory and practice, therefore, the States and the Federal Government act as partners, each contributing to the job of improving the health of the American people.

The basic authority for the bulk of the Department's dental health activities is Public Law 755, passed by the Congress in 1948. This law, as you know, created in the Public Health

Service a National Institute of Dental Research. It directed the Public Health Service to "conduct, assist, and foster researches, investigations, experiments, and studies relating to the cause, prevention, and methods of diagnosis and treatment of dental disorders and conditions"; to "promote the coordination" of dental research; to provide fellowships and traineeships to qualified young research workers in dentistry; and to "cooperate with the State health agencies in the prevention and control of dental diseases and conditions."

The Problem of Dental Education

The Nation's dental schools are in or are confronted with serious financial difficulties. A recent estimate of the need, based on data collected jointly by your Council on Dental Education and the Public Health Service, indicates that the schools require \$43 million for construction to relieve overcrowded classrooms, expand clinics, and develop research programs; \$6.9 million to purchase equipment; and, not counting amounts reported as deficits, an additional \$8.2 million for adequate annual operations. Many schools rely excessively on part-time staffs, especially in the clinical departments.

Unless the financial status of dental schools is improved, the problem will have grave consequences for the quality and quantity of dental service in the future. More adequate support of dental schools seems clearly indicated to forestall any deterioration in dental education.

Potential sources for these funds, which need more exploration, are gifts from individuals and foundations and from industry. Recently, American industry has taken an active part in supporting the medical research effort of the Nation. It is an extremely significant and praiseworthy development. Members of the dental profession themselves, in the interests of good citizenship and the advancement of their high calling, can do much to enlarge the support of dental schools from all these sources.

The problem of dental education is basically, however, the problem of the university schools of dentistry. Here, the dentists of the future receive their basic training and education. Adequate facilities, resources and teaching per-

sonnel are necessary for both research and education in the field of dentistry. Continuing efforts must be made to provide adequate support to dental schools and institutes of research, because it is from these institutions that scientific advances in dental health will be made. The quality of dental care in the future, as in the past, will stem from these advances in both research and education and from their translation into preventive dentistry and dental practice.

Within the State and regional communities can be found the energy, the resources, and the know-how to solve these problems. It is not the job of local government alone; or of the local society alone; or of the practicing dentist alone; or of local philanthropy and civic enterprise. All of these groups and agencies, working together must—and can—find the answers.

The role of the Federal Government in the field of professional education is primarily one of fact-finding and analysis, stimulation and guidance. Federal subsidy or compulsory national health insurance is not the solution.

Expanding Dental Research

The problem of expanding dental research is related to, and, in part, a consequence of the financial crisis in dental education. The American Dental Association recognized early the potentialities of research in terms of dental health benefits to the Nation. With funds derived from its membership, it supported the establishment of fellowships at the National Bureau of Standards, the Armed Forces Medical Museum, and the National Institute of Dental Research.

These modest investments have paid rich dividends. For example, the research undertaken cooperatively by the American Dental Association and the National Bureau of Standards has developed processes and materials which have been widely adopted by industry. The research output of this program is followed eagerly by scientists of other nations, and it has had worldwide application.

Since the passage of Public Law 755, the Federal Government has been able to help in this field. Dental research in the Department

of Health, Education, and Welfare now ranges from basic physiological work to analyses of dental practices and of administrative patterns of organizing dental care.

Research studies include work on oral bacteriology and diseases of the soft tissue. Through the use of the electron microscope, the National Institute of Dental Research has advanced our understanding of the nature of dental decay and of the cell structure of dental tissue.

Another Departmental study is the Public Health Service's investigation of the use of chair-side dental assistants to increase the productivity of the individual dentist as well as the total output of dental services. Many dentists are already availing themselves of the services of trained assistants with decided effect.

The Public Health Service's 14-story Clinical Center at Bethesda, Maryland—which combines facilities for basic laboratory research and large-scale clinical observations—has set the stage for a fully integrated study of the major health problems of man. The Center contains facilities for research in the clinical aspects of dentistry and will enable our dental scientists to conduct studies on patients, with the help of basic research developed in earlier years. Projects are already under way in the study of oral tumors. Others are contemplated in the prevention, diagnosis, and treatment of dental diseases. Our aim in this research—as, indeed, in most of the Department's research—is to find and make available to the private practitioner the tools and techniques which will enable him to do a better job.

Probably the best known research is that which established a relationship between the amount of fluoride in water supplies and the extent of dental decay, and the subsequent and continuing work on the prevention and control of dental decay through fluorides.

But Public Health Service research has gone beyond the dental effects of fluorides. Data have been accumulated on the general effects of fluorides on the functioning of the body, and we are acquiring considerable engineering and chemical information on the water fluoridation process. In fact, one recent finding has been the demonstration in the laboratory that even under extraordinary conditions of mineral or

dietary stress, fluorides in the recommended concentrations do not become toxic.

The Public Health Service is continuing its own research and is watching closely the work of others in this field. We intend to leave no stone unturned in our constant vigilance to protect the public health and safety of the people of this country. I am delighted to see, in view of our findings and those of other research workers, that the American Dental Association has taken the lead in this field of public health. Research offers seemingly limitless possibilities in the control and prevention of dental diseases. The Federal Government has played, and will undoubtedly continue to play, a significant role in dental research.

The challenge to the profession is clear. Knowing the seriousness of dental disease and its costly impairments to health, the profession must seek to stimulate new interest on the part of individuals, foundations, and industry in the problems of dental health. There are many avenues for research which hold great promise that can and should be explored.

The Application of Scientific Knowledge

The application of valid research findings must be hastened, and the best possible dental care must be available to all people.

Our earliest knowledge of dental needs stems from a survey of 1½ million children which the Public Health Service carried out in collaboration with the American Dental Association in 1933-34. I cite this not only as the earliest instance of cooperation between our organizations, but also as a particularly good example of the kind of teamwork in which we believe. The Public Health Service worked closely with some 8,000 local dentists, with State and city departments of health and education, and with State and local dental societies.

As to the Nation's unmet dental needs, the best available evidence suggests that despite the universal occurrence of dental disorders, less than one-third of the population receives anything approaching adequate dental care each year. Although more than \$1 billion was spent for this care by Americans in 1952, it

remains true that many millions of our citizens are either receiving no care or, at best, very limited services.

The opportunity to secure dental care is a fundamental need of every individual. The ideal of dental care for all, however, cannot be realized immediately. Good sense suggests that we place greater reliance upon local initiative and interest. Aggressive support and participation by the community are essential ingredients.

Various experiments have been undertaken which demonstrate the almost limitless potentialities of this idea. Consider, for example, how one small community in Minnesota, with no resident dentists, made dental care available to all children, regardless of income or geographic location. A revolving fund from contributions by families of the community was set up. Interest-free loans to needy families were made for the purpose of financing children's dental care. The families have free choice of any 1 of 6 private practitioners in the county, who provide the care in the school dental office of the community. This is a dramatic example of how a local community voluntarily mobilized its resources to meet a local need.

One largely rural State, North Carolina, recognizing the need for additional dental manpower, appointed a dental college committee as long ago as 1921 to press for the establishment of a dental school within the State. The concrete results of that effort will appear in 1954, when the school graduates its first class. The yearly addition of 40 to 50 dentists will appreciably increase the supply and tend to equalize the distribution within the State. In addition, this State has displayed energy in organizing treatment of underprivileged children by private practitioners and has given thought to scholarship assistance to residents to attend dental school.

These are but two examples among thousands of what can be done through local leadership to provide adequate support for dental care in accordance with the need at the community level. It is a great challenge—a unique opportunity for initiative and imagination in the service of one's fellow men.

Agenda for a critical exploration of Current Problems in Medical Care

By E. M. BLUESTONE, M.D.

Here is a catechism—but with questions only. The author draws here upon his extensive experience in hospital administration and his pioneering work at Montefiore Hospital in New York to ask, cogently and incisively, the perplexing questions current today in the fields of hospital and medical services administration. When originally presented last December his audience was United Community Services of Metropolitan Detroit, but his "agenda" is for all who plan and direct the course of health and medical affairs in private and governmental hospitals, in public health, in social service, and in the civic and official organizations of the community. From them the answers must come.

THE MODERN STUDENT of medical care seems almost to be laboring under an embarrassment of riches these days, so much successful experimental material is at his disposal. Social and medical possibilities are clamoring for conversion into actualities at such a rapid pace that the planner is left breathless in the process. We shall have to excuse his enthusiasm on the one hand and his disappointment on the other when he finds the going slow. Opposition must be met, satisfied, or overcome. New problems are sometimes created as old ones are solved. The best example of this seeming paradox is found in the lengthening of the life span, which, however desirable, brings with it the necessity for making the later years comfortable. The problem in procedure is therefore how to apply new remedies for old difficulties and how to find additional remedies—an unending chain.

The most extensive, and perhaps the most dif-

ficult, of the basic problems is the one the patient exhibits when he is suffering from prolonged illness, whether he is ambulatory, bedridden, or alternating between the two. Here is an exceptional case in which the solution of one major problem automatically liquidates a great many others. Relieve the chronic difficulty and the acute difficulty will be relieved in the process. Since one of the penalties of greater longevity is that it takes a longer average time to die than ever before, we are all the more constrained to deal with this manifestation intensively. That the approach is social, economic, and political, as well as medical, goes without saying. The family and the environment play a major role in any consideration of such a subject. Preventive medicine and environmental medicine hold many keys that are ready for use.

Listed here are some of the items on the agenda of unfinished business, with explanatory

notes, for the consideration of the participants as they deliberate such questions at the council table. Each of these items calls for decisive action and each requires a combination of social and medical techniques in research, which are at our disposal, ready for study and application.

1. We need a definition of such terms as "acute," "chronic," "convalescent," "custodial," "aged," "hospital," "home," "curable," "incurable," "social medicine," and "socialized medicine." At the moment, the sick man suffers patiently while those who plan for him too frequently permit themselves to be confused by these terms.

At what point, for example, shall we separate acuteness from chronicity? Can we establish a common denominator for the two and use it for all practical purposes? What is the impact of duration of illness on the provision of medical care, and does the service correspond to the requirements of the case? How is a convalescent patient distinguished from a so-called chronic patient? Is there any advantage in providing for the elderly separately and apart from all other social and medical services? Or is it better to identify them with all other age groups in accordance with their social and medical needs? When are we justified in labeling a patient "custodial" with regard to medical care? At what point, if any, during the course of illness is a hospital justified in dismissing a patient and transferring him to less capable hands?

It is easy to see how hospital policy can be revised and formulated on a more equitable basis when such questions are answered correctly and in absolute terms in relation to each other.

2. The trends in medical care for each of these definitions need stating, particularly with reference to prolonged illness (formerly known hopelessly as chronic disease) and the aging process. Most of these are well known, even though we resist their full acceptance, while others still wait to be brought to public view in a practical way. There is, for example, the continuing trend toward finding new ways of closing the gaps in hospitals between (a) acute and chronic; (b) income and expenditure; (c)

space demand and space supply; (d) social service and medical service; (e) intramural and extramural care; (f) current medical economics and the science of medicine; and (g) principle and practice generally.

This involves the consideration of such things as voluntary prepaid insurance plans, including group medical practice; home care for those who do not require a hospital bed; and substitutes for the patient's home under the medical jurisdiction of the hospital for those who do not require a hospital bed and cannot be taken care of in their own homes, either immediately or by subsidy of one kind or another. The outpatient department's services will have to be considered; provision of doctors' office space on hospital premises; the integration of tuberculosis and mental disease in the work of the general hospital; the principle of full-time medical service in hospitals; the shifting emphasis in medical education; and the reunion (including the integration) of health and medical care. The obvious purpose in appraising these trends is to apply them productively to plans for medical care.

3. We need an evaluation of social and medical pressures, tensions, and resistances in connection with illness in all its forms. What is the quality and quantity of these individual and communal phenomena emanating inside or outside of the hospital? Are they well based, honestly applied, and helpful? How much anxiety, as well as eagerness, is associated with them, and, if these pressures are well-founded, how shall we deal with the resistances which they may create? The answer to this question will take us beyond the realm of statistics. Workers in the field are constantly exposed to these manifestations and are sometimes caught between the proverbial millstones. This subject must be treated at the council table with statesmanlike understanding.

4. A practical formulation of the scientific requirements in the management of prolonged illness is needed. This refers both to medical necessity and to social necessity, evaluated with scientific accuracy wherever possible, but with the realization that a sick person must never be subjected to the rigid standards of the exact

sciences. Scientific requirements go beyond the goal of certain well-meaning philanthropists who feel that food, shelter, and clothing (custodial care) are all that may be required by a person who has the misfortune of living under a prognosis of incurability.

5. We need a forceful statement on the menace of rigidity in hospital planning, and this refers to function as well as to structure. In particular, we must be alert to this menace when we plan for prolonged illness, because rigidity commits the hospital "in bricks and mortar" over a long period of years during which adaptations will undoubtedly be required. One of the architectural problems is how to get flexibility of design so that adjustments to changing conditions may subsequently be made easier.

6. We need a reaffirmation of the principle of individualization of care for patients under all circumstances. There is now the possibility of home care programs, which, in turn, stimulate greater interest in individualizing the care of patients who have no choice but to enter a hospital.

7. Among the supporting statements for the various items on this agenda should be a well-reasoned critique of the older and still prevailing methods of dealing with prolonged illness in homes, hospitals, and elsewhere. Only on the basis of such studies will revised plans for patient care find acceptance. We must be sure that we are dissatisfied with what we have and profit from experience before we adopt substitutes. A conservative point of view requires the strongest hypothesis to justify any kind of experimentation.

8. The criteria for admission to any hospital will have to be redefined and restated in the light of the deep-seated changes which the laboratories of modern medicine have been offering. Having emerged from the prescientific era, we are now in a position to get a better turnover of hospital beds or offer them to patients for longer periods, as necessary—so long, in fact, as they may have to remain close to the highly concentrated diagnostic and therapeutic facilities of the hospital. The new resource of

home care can relieve the hospital of the necessity for retaining any other kind of patient within its walls.

9. As the policies which govern the admission of patients to general hospitals are rewritten, we should, at the same time, outline the criteria for the retention of the patient in his own home. Under what circumstances is he best cared for in this way?

10. Another item on the agenda is a recommendation on the criteria for the transfer of a patient, either from the hospital or from his home, to a substitute for his home. If a home for the aged, like a so-called home for incurables or a nursing home, should be a substitute for the patient's own home, then we should restate the conditions under which guests may be admitted and retained in these establishments. We must, however, keep in mind that these institutions are substitutes for the patient's home and never for the hospital.

11. The time has come to restate the special criteria for admission to homes for the aged. If we are to discontinue the practice of establishing so-called hospitals within homes for the aged, there is all the more reason for revising the conditions for admission. In the rare instances in which a home for the aged has been able successfully to establish a hospital within its walls, it has in fact added another hospital to the community. In order to establish a hospital within a home, the institution must be prepared to meet the challenging clinical problems which characterize prolonged illness and age in general. It should be able to absorb acute medical and surgical cases without further effort. Such an institution is indeed compelled to do this in emergencies. In connection with this item we must consider the relationship of a home for the aged, which as I have already pointed out is a substitute for the patient's own home, to the general hospital from which it should be able to draw medical sustenance.

12. What criteria shall we recommend for admission to custodial establishments generally? These decisions should follow the lines

recommended for an institutional home for the aged.

13. If, after careful study, we find that it is virtually impossible to maintain a convalescent establishment solely for this specific purpose, what shall we do about it? This establishment, too, is a substitute for the patient's home and not a substitute for the hospital. If a convalescent patient is safely on the road to partial or complete recovery from acute or chronic disease, his requirements will doubtless be about the same as those for anyone who is recuperating from overwork and seeks a change and rest on a farm, in mountainous areas, or at the seashore. We must not confuse the convalescent patient with any other type of patient, for if we do, we shall perpetuate a confused and distorted plan of medical care which makes of the convalescent institution a catchall establishment for the admission of patients (with the possible exception of mental and tuberculous patients) who may not be acceptable to the "acute" general hospital.

14. Though much is being said about the place of the tuberculous patient in the general hospital, we are still far from translating this principle into practice. How can the care of the tuberculous patient be integrated with the care of all other patients in the general hospital and what conditions should govern his admission? The active treatment of this disease, based on modern scientific knowledge, and the passive treatment, which characterized the care given previously and still being given, should be evaluated from this point of view.

15. Almost the same questions apply to the mental patient in the general hospital. What are the relative advantages of integration in a general hospital as compared with isolation and segregation in a distant special hospital? If integration is desirable, what is the best kind of experimental beginning and how can the hospital trustee be made receptive to such new ideas?

16. If integration is not accepted as a wholesome trend in the management of the tuberculous or the mental patient, what alternative

structural and functional plan can we safely fashion? Specifically, we have yet to express ourselves firmly on the place of the mental patient in (a) the mental institution, (b) the home for the aged, (c) the home for incurables, (d) the nursing homes, and (e) all other custodial types of institution. Much of this applies to the tuberculous patient. To what extent is it desirable to alienate either of these patients from the environment generally, to which they will be expected to return, and their families.

17. An essential part of the study of this pressing and vital problem is an item about the significance of a waiting list of patients for admission to a hospital and rejected applicants for admission. What is the effect of a waiting list on hospital morale as well as on the patient himself? At this point there must be an offer of alternative methods of care. This study would be incomplete without a thorough analysis of rejectees in any medical establishment. A hospital must not only know and understand what it does, it must know and understand what it does not do, and then help to make good the difference.

18. No study of medical care can be complete without an analysis of the relationship of housing in the community to the program of hospital care. Throughout the ages at least one reason for the existence of the hospital has been the inadequacy of home facilities during certain phases of illness. Such an analysis would lead into a field of study which would produce, in the end, far better use of hospital beds than we have thus far seen, while individualizing the care of the patient outside as well as inside of the hospital.

19. The requirements of good chronic care as seen from the angle of social (environmental) medicine should be considered carefully. A clear statement should be issued after careful study of these requirements, and facilities should thereafter be adjusted to meet these requirements. Specifically, is the home for incurables, home for the aged, convalescent home, nursing home, or hospital for chronic diseases, the best place for this kind of patient? If so, why? If not, why not?

20. How shall the vicious circle between poverty and prolonged illness be broken? At what point does a person require the kind of assistance, social or medical, which will prevent poverty from precipitating prolonged illness and prolonged illness from precipitating poverty? In the long run, they do their deadly work together.

21. What standards should be recommended for the establishment of substitute homes for the homeless patient and for the home-poor patient when intramural hospital service is not indicated? Should medical facilities be added to these substitute resources and, if so, to what extent? If not, how can these substitute homes be related to the work of the general hospital? In some instances only a custodial type of care is required, but in more instances continuous medical care is required. If general hospitals transfer their undesired patients to less capable hands at a time when scientific medical care is most needed, how shall this practice be controlled?

22. In the analysis and the evaluation of the reasons for the current practice of transferring patients from the so-called acute general hospitals to second-class institutions, we should deal specifically with (a) the financial reason for transfer, including a statement of remedies; (b) the medical reason, including a statement of remedies; and (c) lack of space, including a statement of remedies.

23. How shall we define and evaluate for practical purposes such new terms as "geriatrics" and "gerontology" in relation to medical care? What are their possibilities and what are their limitations? Is geriatrics a separate specialty like pediatrics, or a problem in acute illness or prolonged illness as the case might be? In other words, at what point in the calendar of a man's life are we justified in making any kind of arrangements for his medical care that may deprive him of the best that is available to those who were born into the world after him?

24. What is the relative emphasis that is being placed on various phases and stages of ill-

ness and, in particular, the duration of illness? To what extent does the pressure of urgency dominate planning and how much consideration can be given to nonurgent conditions, which may, in fact, be far more frequent and far more devastating in their prolonged effects?

25. An important item on the agenda is the need for placing responsibility for correct and up-to-date planning. Who is responsible when a person is deprived of the kind of social and medical care that he may need at various critical periods in his life? There must be a level at which responsibility can be fixed. What is this level and how shall it be controlled?

26. Since prolonged illness characteristically exhibits diminishing financial returns from patient sources, how shall we make up the social and medical deficit to enable us to restore the sick man to partial or complete usefulness in his community? What are the relative positions of government and philanthropy in an effort like this and what is the position of the practicing medical profession toward this financial problem which involves them automatically? Can we buy medical time and medical interest with money and with opportunity? If so, under what conditions?

27. As we deliberate on the question of financial currency in relation to the care of the patient, we should give some thought to clinical currency. Specifically, to what extent should such a subject as prolonged illness influence medical education and medical research in the hospital, in the home, and in the substitute for the patient's home?

28. An important item on the agenda is an open-minded study of the principle of full-time medical service in the top clinical and laboratory divisions. What are the relative merits of full-time hospital service and the kind of prevailing voluntary service in hospitals which compels intramural and extramural competition for the service of physicians?

29. Since the poor may always be with us and since the intermediate type of institution—too often a substitute for the general hospital—

will doubtless prevail for some time to come, what structural and functional obligations shall we impose on it? I refer here specifically to the possibilities of preventive medicine at one end and rehabilitation at the other.

30. What responsibility shall be assigned and what agency shall publicize any new patterns which may evolve? What methods shall we recommend to obtain the acceptance of the public generally as well as interested persons specifically?

Omitted from this presentation are those problems in political economy which, to be sure, have a strong bearing on the agenda. While I am concerned primarily with good medical care for everyone, regardless of age, social condition, duration of illness or the illness itself,

environmental medicine teaches that employment and a good economic background are prime factors in preventing disease or its consequences. Business and industry have a strong contribution to make in prevention, first by the application of the principles of industrial hygiene and occupational medicine, and second by encouraging a program of rehabilitation that will enable the recently sick to return to work. Fortunately, much successful experimental evidence is available to enable us to reach decisions on most, if not all, of the items enumerated in this agenda. We are left, therefore, with the need for adjusting the social and medical resources evolving patterns of care. Needless to add, there are many opportunities for additional experimental work on a continuing basis until problems like these can be resolved.

Public Health Service Staff Announcements

Dr. Sidney Farber has been appointed to serve on the National Advisory Cancer Council of the Public Health Service for 4 years beginning October 1, 1953. Dr. Farber is the scientific director of the Children's Cancer Research Foundation, Boston, professor of pathology at the Harvard University Medical School, and chief pathologist of the Children's Hospital, Boston. Since November 1947, Dr. Farber has served the National Cancer Institute of the Public Health Service as a special consultant on clinical research problems. He is well known for research on the chemotherapy of cancer in children, particularly leukemia.

Dr. Floyd S. Daft has been named director of the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, by the Surgeon General of the Public Health Service. Dr. Daft, acting director of the Institute since the retirement of Dr. Russell M. Wilder on July 1, 1953, had been assistant director of the Institute and chief of laboratory research since 1951. A member of the scientific staff of the National Institutes of Health since 1937, he has directed nutrition studies, particularly on the B vitamins, and conducted a study of the substance later identified as folic acid. His in-

vestigations have contributed to the understanding of dietary deficiencies causing anemia, cirrhosis of the liver, and other metabolic diseases.

Dr. Maurice C. Pincoffs has been recently appointed to serve on the National Advisory Arthritis and Metabolic Diseases Council by Surgeon General Leonard A. Scheele of the Public Health Service. Dr. Pincoffs has been professor of medicine at the University of Maryland since 1922, and is president of the Medical and Chirurgical Faculty of Maryland, regent and a recent president of the American College of Physicians, and councilor and ex-president of the American Clinical and Climatological Association. For many years, he has been editor of the *Annals of Internal Medicine*.

Dr. Russell S. Boles, internist and gastroenterologist, Philadelphia, and **Dr. Thomas P. Almy**, associate professor of neoplastic diseases, Cornell University Medical College, have been appointed to the Cancer Control Committee of the National Cancer Institute, Public Health Service. Their 4-year terms are effective October 1, 1953. Dr. Boles succeeds **Dr. Charles F. Brandt**, Lewiston, Maine, and Dr. Almy succeeds **Dr. Edmund G. Zimmerer**, Des Moines, Iowa.

Psychiatric Rehabilitation in the Community

By RICHARD H. WILLIAMS, Ph.D.

ANY FULL-SCALE PROGRAM in psychiatric rehabilitation must concern itself not only with what can be done for mental patients in the hospital (1) but also with what actually happens in the community. What services, if any, are given, and what might be done after the patient leaves the hospital?

It would indeed be fortunate if a mental patient could leave the hospital with the mental disease either cured or arrested, and also be completely "rehabilitated," so that he could at once assume his optimal role without further help or specialized attention. Such is obviously not so, in fact. Adequate statistics on rates of readmission to mental hospitals are not available. We do know they are high. It is a fair guess that they are significantly higher than they might be with concerted rehabilitative efforts in the hospital and in the posthospital period. In New York State, for example, one-third of all admissions to mental hospitals in 1947 are readmissions (2). Readmission rates, where available, may underestimate the

problem, however, because patients returned from convalescent care or from some status other than full discharge may not be counted.

The extent of rehabilitation cannot be fully measured by readmissions because the patient may fall considerably short of his optimal social role even if he succeeds in remaining out of the hospital. Still more basically, it can never be expected that all patients can be fully rehabilitated on leaving the hospital, because the protected hospital setting is, of necessity, significantly different from many of the situations to which patients return.

Efforts can and have been made to simulate pressures of the outside world in hospital settings. For example, patients may be put through a graduated series of work tasks in which more and more rigid scheduling is involved. But the patient is still "protected" in the very special hospital sense, and there is the problem of readjustment to more normal social situations.

The Meaning of "Community"

Psychiatric rehabilitation has already been defined (1). But what is meant by "psychiatric rehabilitation in the community"? The term "community" is used in a variety of meanings. Within the social sciences, it can be used broadly and analytically to refer to persons who share or participate in something in common, for example, a community of language.

It may be used more narrowly to refer to persons who share the basic conditions of a common life, for example, geographic territory,

Dr. Williams, social science research consultant with the National Institute of Mental Health, National Institutes of Health, Public Health Service, discussed the psychiatric rehabilitation of mental patients in the hospital in the November 1953 issue of Public Health Reports, p. 1043.

Public Health Monograph No. 17, a review of the literature on rehabilitation of mental hospital patients, is being concurrently published with this issue and is summarized on p. 1237.

basic educational, medical, and other services.

It can be used still more narrowly to refer to people who share the basic conditions of a common life and who identify themselves as a primary group. In this last sense, many people do not actually live in communities today, and the most typical examples of communities would be found in peasant villages, or among certain nonliterate people.

The term "community" is frequently, and on the whole rather loosely, used in discussions of problems of health and welfare. It is often difficult to pin down just what is meant, other than known interactions between clients and specific health and welfare agencies.

For present purposes "community" will be defined very broadly and residually to refer to whatever nonhospital setting patients go on leaving the hospital. This definition is broad because little is known about what the "community" is and what it means to former mental hospital patients. An important, initial step in posthospital rehabilitation research is precisely to determine the dimensions of the community to which the patient returns. In a general way, it may involve his relations to a family, a job, a circle of friends and acquaintances, his participation in various organized groups or in civic affairs, and his identification with smaller or larger local groups, including his nation. As research proceeds, community functions and structures as they affect the life of the expatient can be identified much more exactly.

Subdividing the General Problem

A fundamental first step in adding to knowledge of rehabilitation in the community is to make a detailed analysis of the real social world to which a patient returns, whether or not a formal intervention by health or welfare agencies occurs. We need to know:

The type of family, if any, to which he goes back.

The degree of his isolation from, or participation in, primary groups (family, close friends, cliques).

His relation to the occupational world and many other aspects of his group identifications.

The informal institutions, basic cultural

forces, and commonly shared attitudes into which he plunges.

The major objective is not to document these situations historically for each individual patient but rather to determine general patterns which affect large numbers of patients and to assess the rehabilitative or illness-producing values of forces within these patterns. Ultimately, the objective is to find modes of intervention which will increase the rehabilitative value of the total situation. This phase may be called the basic analysis of community structure and functioning.

What kinds of treatment, assistance, or support do patients need after leaving the hospital? These include emotional support, assistance in various kinds of economic and occupational adjustment, and help with living arrangements and social activities. A basic question is the optimal amount of support needed, for there can undoubtedly be too much as well as too little support, and disfunctional passive-dependent attitudes might develop.

How, and by whom, can the treatment, assistance, or support best be supplied? What should the role of the hospital and of the various hospital personnel, such as psychiatric social workers, be after the patient has left the hospital? What kinds and amounts of clinic facilities are needed? What is the extent of the role of the vocational rehabilitation agency? Probably various agencies will be involved in the total rehabilitation process, and effective coordination of their efforts is an important aspect.

What kinds of information—through what channels, to what audiences—might build up communitywide attitudes which would facilitate the rehabilitation process? Basically, what can and should be communicated to whom? A considerable body of general knowledge has been built up in the field of communications research, but, as yet, it has not been systematically applied to problems of rehabilitation.

Some Plans for Analysis

There are a few people throughout the country who have developed some empirical knowledge or who have had some professional training in relation to these problems. However,

we are far from having a systematic body of knowledge about psychiatric rehabilitation in the community which could be communicated and utilized in program development.

As a first step in this direction the Public Health Service's National Institute of Mental Health has recently made a grant to the Harvard School of Public Health to explore the problem and to develop a research design for a full-scale analysis of the Whittier Street area of Boston.

This area, as described by the staff at Harvard, has been the focus of considerable and continuing ecologic and demographic analysis and is currently being used for training and research by the Harvard School of Public Health in cooperation with the City of Boston Health Department. Thus, much of the costly background investigation has already been carried out.

Previous analysis showed that the area has a population of about 60,000, includes a wide distribution of cultural and socioeconomic groups in its 11 census tracts, so that it is possible to compare one subgroup with another. There are three main ones: a very low economic group, primarily Negro, with a stabilized population and a high illness and accident rate; a predominantly Irish working class group, with a stabilized population and a moderately high illness rate; and a middle-class apartment house area, with a geographically mobile population and a low illness rate. Preliminary analysis suggests that annually approximately 100 patients from the Whittier Street area are admitted to Boston State Hospital alone. An equivalent number are presumably discharged from the hospital.

Research techniques in the Whittier Street area will include observation and interviewing in the field, as well as the use of statistics and intensive case studies. During the pilot study phase there will be opportunity to develop and suitably adapt sociologic and anthropological techniques and concepts for this particular type of research. The socioecologic and illness-incidence information already available on the population of the area should provide a strategic baseline for intensive analysis and efficient sampling in the selection of patients and families to be interviewed. It should thus be possi-

ble to compare patients' families with socially and culturally similar families to disclose possible significant variables in interpersonal structure and emotional climate contributing to emotional or mental disorder in family members.

Research of this type should contribute not only to a better understanding of the problems of rehabilitation as such and furnish a sound basis for program development but should also add significantly to basic understanding of sociopsychological factors in mental disorders.

Bridging the Wide Gap

There are, and probably always will be, basic differences between the structure of the hospital and the structure of social situations into which patients go when they leave the hospital. There is growing awareness that at present the resulting gap between the hospital and the community is quite wide indeed. This "psychological distance," as Schwartz calls it in *Public Health Monograph No. 17 (3)*, may well account for the relatively large number of failures among discharged patients on the one hand, and for reluctance to discharge many other patients on the other hand. Thus, if the gap could be narrowed or, better still, actually bridged, there could be significant increases in the number of successfully rehabilitated mental patients.

The several ways in which this gap could be bridged may be classified into four main areas, each one of which will require major efforts in research and program development.

The Hospital Itself

Changes within the hospital, including administrative changes, the addition of rehabilitative services, and increased interaction between the hospital and community could make the gap less extreme. There is already a tendency for mental hospitals to be less isolated geographically and socially. There are efforts to bring in more of the outside world as patients are ready for it. Hospital personnel are becoming more aware of working closely with other agencies in the community.

The Patient's Immediate Contacts

It should also prove valuable, while the patient is still in the hospital, to work with the

people who are "significant persons" to the patient—his family, friends, employer, minister, and the others. They could be better prepared to receive the patient and to foresee the problems he will have when he returns. Also, by this same process, much could be learned concerning the patient, his problems, the situations from which he has come, and the situations to which he could or could not return.

Transition Rehabilitative Services

Direct rehabilitative services to the patient after he leaves the hospital could lessen the more extreme changes and severe adjustments in making the transition to a nonhospitalized pattern of life. This could include provision of outpatient clinic services for continued therapy or emotional support, the services of the vocational rehabilitation agency in providing counseling, guidance, placement, and, for some patients, training, services for family counseling and guidance, and possibly others.

The Halfway Shelter

Increased facilities of the character of a halfway house to act as a very specific bridge may prove to be highly desirable and valuable. Schwartz (3) has analyzed several such attempts, and Jones (4) has described a number of arrangements of this type found in different countries. They may take the form of special living arrangements where expatients can find some protected shelter and mutual support, plus a minimum of professional help. The expatient can begin employment, contribute to his own support, be much less of a burden on public funds, and learn gradually to live in the outside world.

Expatient clubs without living arrangements can also be of value. They have been tried with some success in England and on a smaller scale in the United States. Provision for foster homes or other kinds of home care with one or sometimes more patients present in the household also appears feasible and valuable. On the basis of past experience, it is particularly important to have careful selection and preparation of the family and of the expatient, and to have good but not overdone publicity by press and radio to build receptive attitudes in the community generally.

Sheltered workshops can be a valuable bridge in the occupational sphere and provide, as well, a more permanent place for patients who may never be able to function in most occupational settings. But, again, research of the general type indicated above should provide important guidelines for the development of any of these plans or for several of them in combination.

Adjusting to the Community

On the other hand, we should at least be aware of the possibility that for some patients the gap between the hospital and the community may be in a sense not wide enough, or in another sense, of a very special type.

Take, for example, the situation of the patient living in an open ward. He has ground privileges and can go downtown on occasion. He may have made some close friendships and developed group identifications within the hospital, but he may also have lost all contact with family and friends on the outside. He may have achieved a satisfying vocational adjustment in one of the hospital industries, and, of course, he has an assured place to sleep and three meals a day. He has, in effect, brought the "community" into the hospital. Any other "community," on the "outside," would have little, if any, appeal, and might even be quite frightening. Such an adjustment may be fairly "good" from the point of view of the patient but costly to the taxpayer.

How can a program motivate such patients to move on into a more independent and productive status, without doing something to destroy the values of improved hospital care and improved inhospital adjustment? This problem, too, must be faced in any operationally significant research on rehabilitation on mental hospital patients.

Developments in Vocational Rehabilitation

Small but important beginnings have been made in furnishing the services of State vocational rehabilitation agencies to persons with mental and emotional handicaps. Since the passage of Public Law 113 (78th Cong., 1st sess.) in 1943, several States have developed

specialized programs for psychiatric clients. In some States, a vocational rehabilitation counselor has been assigned full time to a mental hospital. In other States, increasing numbers of such cases have been added to the general caseload. Rennie, Burling, and Woodward (5) have estimated that about 15 percent of the patients who leave mental hospitals need the services of vocational rehabilitation. This figure has been cited frequently since the publication of this pioneering study in 1950. It may underestimate the potential use of such services because of the relative newness of the vocational rehabilitation program and because of the relatively small numbers of cases on which experience has been built thus far. In any event, less than 15 percent of these patients are receiving such services now and there is room for much development in this field.

The National Institute of Mental Health, in collaboration with the Office of Vocational Rehabilitation of the Department of Health, Education, and Welfare, has recently been active in stimulating special training programs for vocational rehabilitation counselors who are working with or who might work with mental patients. Three institutes were sponsored during 1952-53 and three more are planned for 1953-54, making it possible in each of these years for each State to have at least one member of its staff to attend. An analysis has also been made of the background of some of the people working in this field. They were found to be an unusually mature, stable, and highly motivated group. They are beset by many of the strains of a new profession, particularly the strains of budget. There tends to be some pressure to increase the numbers rehabilitated, because dollars-and-cents justification is possible and does make sense in this work. But, by and large, they have developed some very successful programs. However, it was also found that there are urgent needs for further training and research results and for more effective utilization and coordination of all resources in the community. Much of the success so far is based on the practical experience of individual counselors and a few empirical and commonsense principles which have not been systematically explored or analyzed in readily communicable form.

Some Indications of Payoff Value

Rehabilitation can and does pay off in dollars and cents. It can produce substantial savings in costs of hospitalization and even more substantial savings in increased earning power of rehabilitated patients, and, hence, a more effective utilization of our national manpower. Furthermore, rehabilitated patients pay taxes on their earnings which offset the costs of vocational rehabilitation services.

Numerous figures have been compiled for vocational rehabilitation in general, for example: "The 60,000,000 disabled persons rehabilitated in 1950 added an estimated \$93,000,000 to the national income the first year they were rehabilitated—more than three times the amount expended for rehabilitation services in the same period and about five and one-half times the annual rate of \$17,000,000 earned by these individuals at the time they were accepted for service" (6).

Figures indicating costs and savings in the total rehabilitation of mental patients have not been compiled. However, in an analysis made of one State program by the National Institute of Mental Health, it is clear that savings through vocational rehabilitation of mental patients were substantial. In the first 4½ years of the period analyzed, during which a vocational rehabilitation supervisor was assigned full time to the State hospital, 238 cases were closed as rehabilitated. The rehabilitated patients earned a total of \$256,304. This figure would give a fictitiously low average, because a number of the patients counted had been out of the hospital and earning salaries only a few weeks at the time of the study; the average weekly wage is about \$50. The costs of keeping them in the hospital during the period they were employed and out of the hospital would have been \$449,222. Thus, there was a gross gain in values produced and in savings of \$705,526. If we estimate that they paid 15 percent of these earnings in various taxes, there was a tax return to the public of \$38,445, or a gross gain to public funds of \$487,667. The program cost \$6,478 in direct services to clients (tuition for training, and other costs), and \$46,358 for guidance and professional services, or a total of \$52,836. If we attribute all of the

hospital savings to the program, there would be a net gain of \$434,831 in public funds. Some of these patients would have been out of the hospital without the program. However, we only need to attribute about 5 percent of the hospital savings to the program to have it pay for itself in public funds alone, and undoubtedly the program accounts for several times this amount.

These figures look, and are, convincing. However, too much insistence on this type of argument is likely to create pressure to turn people out in quantity. Cases are sometimes closed too soon and cases which do not need service are taken in order to make a better record. We should always bear in mind that we are not producing machines on a mass production basis. Rather, we are attempting to help people lead more satisfactory lives which in turn create many intangible values not only for themselves but for those with whom they are associated. Some of these values are more difficult of measurement. However, it seems quite safe to conclude that programs in reha-

bilitation have a very high potential payoff, both in terms of values which can be measured directly in dollars and in terms of the less tangible human values which cannot be so measured.

Cancer Control Letter Discontinued

Publication of the monthly *Cancer Control Letter* was discontinued, by direction of the Bureau of the Budget, with issue number 67 dated September 1, 1953. The National Cancer Institute of the Public Health Service had issued these reports as a service to public health officials, voluntary health agencies, educational institutions, and others concerned with cancer control activities and techniques. Every effort will be made to supply the information furnished previously by the Letter through publication in *Public Health Reports* and other publications and agencies.

The Literature of Rehabilitation Of Mental Hospital Patients

Within the past few decades personnel working with hospitalized mentally ill patients have increasingly shifted the conception of their purpose from custodial care to reeducation and reintegration of the patient into his community. They have become more aware of the necessity for treating the patient as more than a carrier of a disease entity. The new concept of rehabilitation of the mentally ill is the rubric under which a wide variety of activities is carried on. However, despite the growing body of published reports regarding rehabilitation practices, there has been no general survey of the literature in this field. Public Health Monograph No. 17 reports an analysis of 189 selected articles in this field published in the United States between 1944 and 1952.

Writers have defined "rehabilitation" in various ways, depending upon their purposes and viewpoints. Rehabilitation has been conceived of as the activities which bring about patients' recovery, the process by which patients recover, the goal of the services provided, or a phase of the treatment given. In this report an operational definition was used. Rehabilitation is defined by indicating what is being done to aid patients to function outside a hospital setting. The report does not cover specific medical therapies or psychotherapy.

Five questions are considered:

1. What is the unit of rehabilitation? In other words, what aspects of the patient or patients must be considered in a rehabilitation program and what are the number, kinds, and organization of personnel necessary to carry on rehabilitation services? Five currently used approaches are described: the individual approach, the team-individual approach, the pa-

Public Health

MONOGRAPH

No. 17

The accompanying summary covers the principal points discussed in Public Health Monograph No. 17, published concurrently with this issue of Public Health Reports. The author is with the National Institute of Mental Health, National Institutes of Health, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

• • •

Schwartz, Charlotte Green: Rehabilitation of mental hospital patients. Review of the literature. Public Health Monograph No. 17 (Public Health Service Publication No. 297). 76 pages. U. S. Government Printing Office, Washington, 1953.

tient group-individual staff member approach, the patient group-staff team approach, and the interpersonal relationship approach.

2. What is the process of rehabilitation? The differences in the conceptions of how rehabilitation occurs are pointed up by classifying activities in terms of the major focus of the writers. It is shown that relationship therapy, patient-patient relationships, group psychotherapy, psychodrama, group discussions, therapeutic social clubs, group work, and patient government are mainly conceived in terms of the interpersonal relationships involved. On the other hand, occupational therapy, music therapy, art therapy, recreational therapy, and corrective therapy are conceptualized primarily in terms of the activities involved. Attempts to combine both approaches in total push programs are examined.

3. Which staff attitudes toward patients are thought to be therapeutic and which are considered nontherapeutic? The ways in which patients are affected by these staff attitudes are delineated.

4. Which aspects of the hospital social structure are thought to be related to patient improvement? The following areas of hospital structure are examined: the degree of democratization of the structure, the channels of communication, the definition of the functions of hospital personnel, and the atmosphere of the ward. In addition, the effect of the hospital physical plant on patients is indicated.

5. What ways are used to bridge the gap between the protected environment of the hospital and the more unprotected existence of community living? The approaches which can be instituted while the patient is in the hospital and those which might be instituted after the patient returns to the community are suggested.

Throughout the monograph, attention is focused on core problems faced by rehabilitation workers and, on the basis of activities thus far conducted, suggestions for further research are advanced.

From THE CHILD

Of Public Health Interest

In the November 1953 issue, Margery D. McMullin, executive director of the Handicapped Children's Home Service in New York City describes how "To Keep Up Home-Bound Children's Morale" by recreational activities which are stimulated by "volunteer" visitors to the homes.

And John G. Hill, research director of the Health and Welfare Council, Philadelphia, considers the question, "Can Cost Accounting Help Social Agencies?" He describes the experience of the Family Service of Philadelphia in analyzing its unit costs of service and mentions that the family agency, one of the 10 largest in the United States, is publishing a cost study manual. (Copies may be purchased upon publication by addressing the agency at 311 South Juniper Street, Philadelphia 7.)

Also in the same issue, the efforts of a local committee in bringing community health and education services to the families of mi-

gratory agricultural laborers in Fresno County, Calif., are described by the committee's vice chairman, Mrs. I. H. Teilman.

In the October 1953 issue, Dr. Anna L. Philbrook, director of the New Hampshire State Child Guidance Clinics for the past 10 years, discusses emotional problems of the crippled child, in an article based on her report at the 18th New England Health Institute. She writes, "We should not let the crippled child depend on us too much, but rather we should show him that we are aware of the force of health that is in him. Let us give that force a chance to strengthen itself . . ."

The Child will be changed in name to *Children* and issued bimonthly beginning with the January-February 1954 issue. The subscription rate is \$1.25 a year (\$1.75 for foreign mailing). Single copies are 25 cents each. The publication is issued by the Children's Bureau, U. S. Department of Health, Education, and Welfare.

An Analysis of Ratbites In Baltimore, 1948-52

By WILLIAM SALLOW

THE PROBLEM of persons being bitten by rats is often superseded by the more pressing problems associated with rodent control. If the situation were merely mechanical, the treatment of a laceration or wound, while important, would not be too significant. However, when the rat is so closely associated with man that it can bite him, the possibility of disease transmission exists from the vectors present or from such pathologies as leptospirosis, salmonellosis, or ratbite fever.

The establishment in May 1947 of a separate division of rodent control in the Baltimore City Health Department resulted in focusing attention on the incidence of ratbites as an important phase of a control program.

The data presented in this report was accumulated by the division of rodent control on a citywide basis. Hospital records were checked wherever possible, and each victim or his family was interviewed. A previous study by Richter in 1945 (1) was based on data from a limited area of approximately 2 square miles, known in Baltimore as the Eastern Health District. The differences between the data of the two reports can be attributed to the greater scope of the present report.

Ratbite Case Reporting

In Baltimore, a city of more than 900,000 persons which at one time had a rat population thought to equal the human population, there is no provision for the compulsory reporting of ratbites. No cases of ratbite were reported prior to January 1948, but in that year a total of 14 ratbites from 14 separate locations was reported to the division of rodent control. Of this total, 36 percent of the ratbites were re-

ported by the police, 50 percent by relatives or friends, 7 percent by the admitting hospital, and 7 percent by miscellaneous sources. On the other hand, 42 percent of the cases were treated at a hospital.

Of 322 ratbites tabulated between January 1, 1948, and December 31, 1952, hospitals reported 31.7 percent of the cases to the health department, thus leading in the reporting as would be expected, since 231 or 71.7 percent of all the persons bitten were treated in hospitals. Parents and relatives reported 21.7 percent of the cases. Private physicians treated 8.4 percent of the bites but reported less than 1 percent of the total (table 1).

These statistics, however, do not reveal the true picture of the great improvement that has been accomplished in reporting. In 1948 hospitals reported 7 percent of the ratbites, and in 1951 more than 54 percent of the reports came from this source. The figures for 1952 again show more than 50 percent of the ratbites were reported by hospitals. The reporting by physicians, while not as spectacular in improvement, continues to show an increase. Approximately 15 percent of the reports were from within the health department, the cases having been discovered by sanitarians or public health nurses. The police have been invaluable in their assistance by reporting over 13 percent of the bites.

All such information is secured without benefit of a definite requirement for reporting and can probably be attributed to the educational activities of the health department as well as the excellent cooperation of the hospitals and the others involved.

Ages of Victims

Children 6 years of age or less are the predominant victims of ratbites. Approximately 60.5 percent (195) of all victims were in this age group, and 24.8 percent (80) were infants less than 1 year old. An additional 11.2 percent (36) occurred in children from 7 through 12 years of age; 6.2 percent (20) occurred through the age of 21, while 16.1 percent of the total were reported for persons over 21. In approximately 6 percent of the cases no age was reported (table 2).

Mr. Sallow is chief of the division of rodent control, sanitary section, Baltimore City Health Department.

In approximately 80 percent of the cases, the victim was bitten while asleep, generally in the very early morning. Of course, incidental bites have occurred through inadvertence, as for example, a policeman who was bitten on the ankle while interrogating a householder, or the young school boy who chased a rat and caught it.

Thus it can be assumed that the next Baltimorean to be bitten by a rat will probably be 6 years of age or under, possibly an infant of less than 1 year. He will be treated at a hospital, which will then report the case to the division of rodent control. Chances are the victim will be bitten on the finger or hand, for 161 of the bites covering the 5-year span of this report were on hands, fingers, or arms; 68 were on legs or lower extremities, and 70 on the head or about the face.

More than the average number of ratbites occurred from June through November with a peak during July and August. February has been the month of least activity, closely followed by January and December. In 1951, however, bites in January and February were higher than the monthly average for that year, and no bites were reported in June. Thus, experience to date has indicated that ratbite occurrences are not predictable on a seasonal basis.

Geographically, 90 percent of the ratbites reported have occurred within 2 miles of the center of Baltimore. There is a well-defined area of occurrence west and northwest of the business district, another slightly smaller area east and

still a smaller clump south of this district. The business district, on the other hand, remains relatively free with but 1 or 2 reported cases in the 5-year period. These areas in which ratbites occur are in general "the blighted areas" of the city.

In an attempt to draw an analogy between ratbite occurrences and complaints by the public concerning rat infestation an apparent ambiguity is presented. More persons complain about rats from outside the ratbite area than from within it. Therefore, the assumption may be drawn that in these bad areas, the inhabitants are either complacent about the rat problem or unaware of the assistance afforded by the municipality. Relying on experience, the inclination is toward the former assumption—these people apparently are not too concerned about rats as an immediate problem of daily existence.

Rodent Control Operations

As the cases of ratbite are brought to the attention of the division of rodent control, a sanitarian is assigned to investigate each case. A complete inspection of the property involved is made and a survey of adjoining properties and the exterior of the entire block is completed. As a general rule, the premises on which ratbites occurred were found to be moderately to heavily rat infested.

A random selection of cases indicates rats usually entered cellars or basements through

defective or rotted doors or window sills and open unscreened basement windows. The heaviest rat infestations were found under wooden floors constructed over dirt surfaces in basements. Crawl spaces, varying from 6 inches to 3 feet deep, under a portion of the ground floor where basements were not fully excavated were also heavily infested.

Once the rat has gained entry and has established a harborage, its progress throughout the remainder of the premises is in direct proportion to the interest the occupants have in eliminating it and the abundance of food that is available. The rat migrates to the kitchen for obvious reasons and as it builds up a family, it occupies more of the house than man. The rat uses available areas such as spaces behind walls and between floors. In addition to structural harborage, it can be assured of such incidental homes as those provided in trash and debris and "saved" materials stored in basements, closets, and occasionally in an attic.

All necessary corrections to accomplish rat-proofing, rat eradication, and improvement of sanitation are instituted under the guidance of the health department. On the infested premises in which ratbites occur, eradication measures must be undertaken immediately by "competent persons," and the division requires notification of the time and the manner of such procedures. Improvements in sanitation and ratproofing must be accomplished within a time limit prescribed by the notice. The notices may be pursuant to the general nuisance abatement ordinance or the provisions of the Ordinance on the Hygiene of Housing.

Dangers From Rats

Where rats become so intimately associated with man that they share the same abode and

leave their mark on the anatomy of man, disease implications are apparent. "Where the mean temperature is 45° or less, fleaborne diseases appear to be occasional, accidental, and self-limited" (2). Fortunately, Baltimore is well north of the average winter temperature zone of 45°. Nonetheless, in this city it is possible to import flea-infested rats which find harborage in warm basements.

It was just such an "accidental" situation which occurred in late 1946 and early 1947 when 7 cases of endemic typhus with 1 fatality occurred in a crowded row of houses not far from a local railroad line (3).

No evidence of plague in Baltimore could be found by complete search of city health department records. However, as recently as early 1951, a case of ratbite fever (*Spirillum minus*) was diagnosed in a local hospital, and in 1951 and 1952 the first 3 cases of Haverhill fever were recorded (4).

The presence of *Leptospira* in significant proportions in the rat population has been demonstrated in local studies (5) and confirmed by several cases of leptospirosis. Although typhus, plague, and leptospirosis are not transmitted by ratbites, it is well to consider the three diseases whenever rats live in close proximity to persons. The role of rats in ratbite fever, also known as Haverhill fever, has been defined by the authorities with the exception of the occurrence of sporadic cases of Haverhill fever without recorded reference to ratbites (6).

The high percentage of ratbites occurring in children 6 years of age and under gives some cause for reflection. Why the preponderance of victims in this age group? Is it possible that rats sense the defenselessness of the very young? Perhaps these occurrences can be at-

Table 2. Annual number of ratbites within age groups

Year	Under 1 year	1-6 years	7-12 years	13-21 years	Over 21 years	Age not determined	Total
1948	1	5	0	0	0	8	14
1949	20	26	7	6	3	7	69
1950	18	26	9	6	16	5	80
1951	16	19	8	6	10	0	59

Total	80	115	36	20	51	20	322

tributed to some extent to carelessness or neglect by parents in failing to cleanse the child after feeding and before putting him to bed. Many persons have reflected on this problem without providing more than theoretical assumptions. Only through the continued and concerted efforts of the health department directed toward eliminating those environmental factors that favor rat propagation and rat life can we hope to reduce the occurrences of ratbites and the potential ratborne disease hazards.

Summary

Baltimore does not require reporting of ratbites. However, through education by health officials and the excellent cooperation of hospitals and other agencies, this information is now being obtained.

Children 6 years of age or less are the predominant victims of ratbites and the incident usually occurs in the early morning while the victim is asleep. Most often the victim is bitten on the arm or leg. Although not predictable on the basis of present limited data, the peak season for these occurrences appears to be during July and August, and a steady de-

cline is noted to a low in February. Ninety percent of the ratbite incidence takes place within 2 miles of the center of the city. All are investigated and corrections are required by the Baltimore City Health Department's division of rodent control.

The close association of rat to man, as demonstrated by many ratbites, causes reflection as to the potential of ratborne diseases.

Municipal Sewage Treatment Plant Construction

Contracts for 204 projects to abate water pollution and conserve water resources, with a total expenditure of \$64.6 million, were awarded by municipalities during the second quarter of 1953.

Of the 204 projects, 118 are for new plants and 86 are for additions, enlargements, or replacements of existing facilities. Individual projects range in cost from over \$22 million for the city of Miami proper for a new plant to \$1,590 for improvement in San Francisco.

Programs and Problems in Professional Education And Inservice Training of Health Personnel

The evaluators find that the cooperative health programs of the Institute of Inter-American Affairs and the Latin American Republics have made no greater contribution toward the advancement of health and sanitation than through their training and education activities. To hundreds of individual Latin Americans, these activities have meant greater opportunity for the cultivation and exercise of their natural talents. To their countries, they have meant higher levels of technical competence and informed leadership for health and sanitation work.

TWO BROAD PRINCIPLES guided the evaluation of the training and education activities of the bilateral health programs:

1. Well-trained personnel are an indispensable part of the foundation upon which strong and effective organizations are built. Even with a good program, reasonably adequate

funds, and a satisfactory plant, the services provided will be no better than the competence of the operating personnel. The persons responsible for the establishment of the *Servicios* in Latin America were fully aware of this principle, and from the beginning training was accorded a high priority.

2. Training is part of the whole fabric of health services. Training of personnel and provision of facilities for its utilization are in reality a single problem, for if training is not to lose its primary purpose, which is to assure good services, personnel when trained must have a place for employment.

This review of training and education in Latin America is the ninth in a series of excerpts from the Public Health Service's report of its evaluation of the Institute of Inter-American Affairs bilateral health programs undertaken during the decade 1942-52. Information concerning the evaluation survey and the origin and structure of the bilateral health programs can be found in the September 1953 issue of *Public Health Reports*, beginning on page 829. Other excerpts from the report have appeared in the October and November 1953 issues.

Availability of Personnel

An examination of the personnel situation at the time of the survey revealed that, in general, trained personnel were inadequate in number to staff existing health facilities. This was most in evidence in the field of hospital nursing.

Many large hospitals were operating without a single graduate nurse, and many more had very few. In Chile, where nursing was more advanced than in many Latin American countries, a tuberculosis hospital with a bed capacity of 460 had 16 graduate nurses and 74 auxiliaries; the nursing staff of a 380-bed general hospital consisted of 15 graduate nurses and 300 auxiliaries. In Ecuador, where nursing as a profession is of very recent origin, one 950-bed hospital was employing 3 graduate nurses and 24 trained auxiliaries, most of the nursing service being given by untrained aides.

Sanitary engineers, sanitary inspectors, and even physicians were also clearly insufficient in number if entire populations were to benefit from health services. In many of the countries visited, however, little effort to provide health services outside the large urban centers was in evidence. According to the latest figures available at the time of the survey, the entire medical profession of Bolivia was serving only one-third of the population. In Brazil, 75 percent of the physicians of the country were serving the 24 percent of the population living in towns of more than 10,000; only 25 percent of the physicians were available to meet the needs of the remaining 76 percent of the population, essentially rural. A similar situation was found in Ecuador, where 50 percent of the physicians were serving the 15 percent of the population living in the cities of Quito and Guayaquil.

The reason for the concentration of the medical profession in cities was basically economic. Only in the large urban areas could a physician earn enough to justify the time and money required to become a physician, and only there were to be found the medical facilities, such as hospitals and laboratories, which would enable him to practice the type of medicine for which he had been trained.

Training Facilities Needed

With the great need for trained personnel in urban institutions, especially for nurses, nurse's aides, and hospital administrators, and an even greater need in the rural areas for physicians, the facilities for the preparation of all types of health workers are apparently extremely inadequate. Many of the institu-

tions claimed that there was not enough money available to permit the employment of a larger number of well-trained personnel and that the imbalance seen everywhere between the need for and the supply of well-prepared workers could not be corrected simply by establishing more educational institutions. Notwithstanding this reasoning, more facilities for training are indicated.

The basis for this judgment can be illustrated by the hospital situation. During the field survey, substantial evidence was found that the average hospital stay, and therefore the average cost per patient, could be substantially lowered by improvements in administrative, medical, nursing, and therapeutic techniques. Under good management provided by a well-trained hospital administrator, the patient stay at the university teaching hospital in Santiago, Chile, was lowered from 26 days in 1946 to 16 days in 1951. In a number of hospitals the average stay of patients with typhoid fever, typhus fever, and venereal diseases had been substantially reduced by the use of certain of the newer antibiotics.

The consequent reduction in costs in the instances cited may be said to bear a direct relationship to the quality of the personnel administering the health services. Savings brought about by improved quality of personnel would be available to increase the number of workers of all categories. The major question, therefore, may not be whether a hospital can afford well-qualified personnel, but whether it can afford to continue operations without such personnel.

Quantity vs. Quality

The problem of staffing a health institution, whether it be a hospital, health center, or other type of organization, involves quantitative as well as qualitative considerations. Again using the hospital for purposes of evaluation, though recognizing that the principles have broad applicability, it may be asserted that in no country will there ever be a sufficient number of professional nurses to perform all the traditional functions of nursing. Even in the United States, where trained nurses are far more numerous than in Latin America, this fact

is now recognized and generally accepted. It has become necessary to study and analyze nursing functions in order to decide which must be performed by the highly trained nurse and which may be safely performed by a person with less training.

The general concept today is that the nursing service of a hospital or a health program may be broken down into groups of functions. Each of these groups may be performed effectively by persons with widely different backgrounds and training. The quality of service will be improved when training is based on the requirements of the functions within each group and the groups are integrated to provide complete patient-centered care. The professionally trained nurses in such a system must be responsible for the training of personnel as well as the coordination and supervision of their work.

Considerable experimentation in the use of subprofessional personnel was being carried on in several countries of Latin America. In the Amazon Valley wide use was being made of auxiliary nurses in the hospitals and *visitadoras* in health centers. In Uruguay most of the public health nursing service of the health centers was being provided by specially trained *visitadoras* working under the supervision of graduate nurses. Many more examples might be cited, but none of them indicate that the quantitative aspects of the nursing problem have been adequately met. Furthermore, in many instances the quality of the subprofessionals' work has left much to be desired.

Further experimentation directed toward a solution of the quantitative as well as the qualitative aspects of personnel employment in Latin America is highly desirable. Nowhere is such experimentation more urgently needed, nor does it have a more favorable environment in which to thrive, than in Latin America.

Inservice Training for Professionals

Apprenticeship training was employed rather extensively in the early years of many of the *Servicios* and continues to be of considerable utility. For example, a United States sanitary engineer on the field party staff and a Latin American engineer untrained in sanitary engi-

neering may work together as a team, the former serving as the tutor and the latter as the apprentice. Over the years a rather large group of competent Latin American sanitary engineers has been created by this method of training. It has also been employed to train physicians and graduate nurses for public health work. Sometimes apprenticeship training was supplemented by academic training through the fellowship program of the Institute. Such training offers an excellent opportunity for identifying individuals who should receive specialized academic training.

Another type of inservice training provided in a few areas of Latin America was the planned conference. For example, the nurses on the staff of the Cerro Barón Health Center in Valparaíso, Chile, were required to attend a weekly conference at which each shared her experiences with the others in regard to special problems encountered and methods used for solving them, successful or not. The advantage of this type of inservice training is that the individual experience becomes the group experience and each person profits.

The planned conference may, of course, include more than one category of worker. All the health center personnel—physicians, dentists, engineers, nurses—may be assembled at regular intervals for the purpose of sharing experiences, analyzing problems, discussing possible solutions, and planning new undertakings. Such conferences tend to weld the group together so that it thinks of itself and conducts itself as a team. A sort of mass-action phenomenon results, producing an effect which is something more than the sum of the individual activities.

Inservice training of professionals should be a constant preoccupation of the administrators of every *Servicio* since it provides the means for continuous improvement in the quality of performance.

Specialized Academic Training

In the early period of *Servicio* operations, it was necessary to send nationals abroad for specialized training. To this end, a fellowship program was established by the Institute, and hundreds of physicians, engineers, and nurses

Top: The National Superior School of Nursing at Bogotá, Colombia, was built and equipped by the Servicio. Center: Student nurses receive instruction from a Servicio staff member in La Paz, Bolivia. Lower: As part of their inservice training linked with field service, the nurses meet with their supervisor to discuss plans.

were sent to the United States. Although this program eased the situation, it did not solve the problem in any country. No fellowship program could ever hope to meet the entire need for specialized personnel; each country must solve the problem in its own way.

At the time of the survey, a number of the Latin American countries had taken steps to provide academic training in various branches of public health. The Faculty of Hygiene and Public Health of the University of São Paulo in Brazil, the School of Public Health of the University of Chile, the School of Public Health and Hygiene of the Secretary of Public Health and Assistance in Mexico, and the School of Tropical Medicine of the University of Puerto Rico were offering courses in such subjects as public health nursing, hospital administration, maternal and infant hygiene, industrial hygiene, health education, sanitation, statistics, and public health laboratory techniques. The Graduate School of the Autonomous National University of Mexico was offering courses in sanitary engineering.

There are distinct advantages to training Latin Americans in their homeland instead of in the United States. It is less expensive since both travel expenses and the cost of living are less. The period of adjustment is shorter because of the language, social, and cultural similarity between the various countries. It is recommended that wider use be made of the Latin American institutions for fellowship training, reserving the United States institutions for special cases.

The men and women who have benefited or who will benefit as a result of specialized academic and inservice training are, for the most part, the product of the various national Latin American schools of medicine, dentistry, engineering, and nursing. Public health as well as medical services, therefore, is conditioned in a very real sense by the quality of medical, dental, engineering, and nursing education.

Logically, any effort to advance a broad health program—one that neglects neither preventive nor curative medicine and one that is concerned with environmental as well as personal health—must take into account all these educational institutions.

Schools of Nursing

Establishing schools of nursing or strengthening those already in existence received considerable attention during the decade under survey. Projects were sometimes undertaken as a joint effort of the *Servicios*, the Pan American Sanitary Bureau, and the Rockefeller Foundation, in collaboration with the appropriate national ministry.

In developing a school of nursing, several factors must be considered: recruitment of students, housing, classroom and teaching facilities, and financial support for the school. Perhaps most important is a faculty capable of planning programs which meet specific needs, developing curriculums for effective learning and practice areas for supervised experience in patient care, and reevaluating the programs to determine how well the objectives have been accomplished.

The National School of Nursing of the Central University of Quito in Ecuador is an example of a project which has shown excellent results in progressive national participation and which demonstrates the possibility of inter-agency cooperation.

Before 1942, there was a school of nursing at the Hospital Eugenio Espejo in Quito which conducted a 3-year course. The school was directed by a physician, and all instruction was given by physicians. The curriculum was limited, and there was no opportunity for supervised clinical experience. There were no residence quarters for the students.

In 1943, at the request of the Minister of Health, two nurses were assigned to Ecuador by the Pan American Sanitary Bureau to assist in reorganizing this school of nursing or if necessary to establish a new modern school of nursing. The decision was to establish a new one. The *Servicio* agreed to reconstruct and adapt a building provided by the Ecuadorian Government to house the new school. The Rockefeller Foundation furnished some of the equipment, assisted in the initial cost of operation, and provided consultation service.

From 1942 to 1949 one of the United States nurses assigned to Ecuador was director of the school of nursing. During 1947 and 1948, an Ecuadorian nurse, a graduate of the first

class, was sent to the United States for a year's graduate study. In 1949 she became assistant director of the school and in 1950 became the director. The Institute nurse continued to give consultation but gradually turned over more and more of the responsibility to the new director. By early 1952 the Government was completely supporting the school of nursing as a part of the university, and the *Servicio* was providing some scholarships to students. An advisory committee composed of representatives of the university and the Ministry of Health was working with the school faculty in setting up and maintaining standards. There has been a continuous attempt to keep the requirements for admission, the provisions for clinical experience, and the curriculum content in line with the needs of the country. At the end of 1951, 98 nurses had graduated from the school and 60 students were enrolled.

At the time of the survey the Institute was cooperating in the building programs of 8 schools of nursing: 1 each in Guatemala, El Salvador, Colombia, and Ecuador, and 4 in Brazil. Assistance was being given to the operation of 12 schools: 1 each in Colombia, Haiti, Ecuador, Uruguay, Paraguay, and Venezuela, and 6 in Brazil. Some technical consultation on nursing education has been provided in all countries, even when no nurse has been specifically assigned for that purpose.

It is doubtful whether the schools of nursing in Latin America should be patterned after those in the United States. Rather, it seems wise to prepare nurses especially (a) for work in those particular fields which constitute the major health problems in their countries and (b) for the training and supervision of auxiliary personnel in hospitals and health centers.

In view of the needs of the countries, it is strongly recommended that continued support be given to schools of nursing. This support may take the form of (a) construction of buildings to house schools and, when considered necessary, to provide housing for the students; (b) improvement of practice areas, which may include use of funds for reconstruction of buildings or purchase of equipment to provide basic essentials for patient care and assistance in improving the efficiency of operation of existing institutions; and (c) assistance, on a consulta-

tion basis, in the administration of the school, curriculum planning, and preparation of instructional personnel.

Medical Education

Analysis of medical education in Latin America was based upon what were regarded as certain essentials of a good school of medicine. Though far from complete, the following guides were found useful:

1. Limitation in the number of students, with appropriate methods for their selection. In most of the countries visited there was no limitation of matriculants. Chile, where the number was restricted to correspond with the teaching facilities, was an outstanding exception.

2. Selection of faculty members on the basis of teaching ability and scientific productiveness. They should enjoy reasonable security in respect to income and tenure. The faculty of the departments responsible for the basic sciences should be able to devote their attention exclusively to their departments without the need to seek additional employment. Relatively few of the schools of medicine observed in Latin America are so staffed.

3. Sufficient school-plant space in lecture rooms and especially in laboratories to accommodate the maximum number of students permitted to matriculate. The scientific equipment and supplies of laboratories should be adequate to permit good instruction in the basic subjects. Hospital wards of all types should be freely available for teaching clinical subjects. Workable relationships should be established with the local health services so that the social and preventive aspects of medicine may be taught. The hospital facilities for teaching clinical medicine were found to approximate adequacy more frequently than any of the other facilities.

4. A good library. Few of the schools observed were adequately equipped.

5. A budget large enough to sustain good operation and administration. Budgets of Latin American schools were reasonably adequate in only a few schools.

In a number of countries, it was apparent that much thought and effort were going into measures for the betterment of medical education. The country was rare in which no attention was being directed to the subject.

Service and Training

Schools of medicine everywhere have a crucial decision to make. Shall they devote their efforts to meeting the countries' needs quantitatively, or shall the quality of their product have priority?

As already mentioned, in many Latin American countries medical services are available to only a part of the population. For this reason there has developed a school of thought advocating the production of more and more physicians even at a sacrifice of quality and insisting that a poorly trained physician is better than no physician at all. This extreme position, as well as the opposite one, appears to be untenable if the best interests of the people are to be served. The solution of the problem in Latin America probably is to be found somewhere between these extremes.

The survey indicated that an important reason for the divergence of views respecting the aims of medical education stemmed from the fact that institutions responsible for education rarely were responsible for providing medical services for the people. A variety of agencies, official and voluntary, were operating in the hospitals, the health centers, and other institutions providing medical services. In most of Latin America, the ministry of health had the chief responsibility; yet, it was rare for this ministry to have more than a very minor voice in shaping policy regarding the number and quality of physicians to be trained to man those services. The ministry of health, the ministry of education, and the schools of medicine should study and plan jointly in order that the product of medical education may be prepared to carry on the type of services needed.

Servicio Responsibility

The fact that medical education has a direct relationship to medical care raises a question as to the *Servicio's* responsibility in this field. It is strongly felt that medical education should receive more attention by the *Servicios* than in the past. The fact that no sure course of action can be forecast should only add zest to the acceptance of an unusual challenge. Study of the many functions of physicians in public service, whether in hospitals, health centers, or

other public health activities, and classification of these functions into those which physicians alone can perform and those which might safely be assigned to other categories of personnel are steps that can and should be made in the near future.

In many areas a division of responsibility has already taken place. Immunization against smallpox and other diseases and the diagnosis and treatment of such diseases as malaria, hookworm disease, and yaws were being performed by nurses and sanitary inspectors. By such procedures it has been possible to bring to remote, rural populations the benefits of modern medicine and public health. It may well be that following painstaking study or job analysis of the physicians' work, organizations could be established, with appropriate safeguards, to extend services still further to such peoples. Success in such work, of course, depends in large measure upon the availability and the quality of supervision by physicians.

Training of Subprofessional Personnel

Training of subprofessional personnel may follow the same general plan as outlined for professional personnel—an apprenticeship type of inservice training and/or academic training. The need for both should be recognized, and both should be planned to assure competence on the part of each type of worker to perform effectively the tasks required. Ultimate responsibility for the training must rest with the professional personnel.

In a number of countries, there was found a body of experience in training subprofessional workers which would prove valuable in the event that the use of this type of worker should be extended. In Brazil, for example, a 6-month course for *visitadoras* was inaugurated at the Colatina Training Center. This course included demonstrations and supervised practice as well as carefully selected basic information. In Bolivia, where efforts to assist with the development of a professional school of nursing had not been successful, primary emphasis was shifted to on-the-job training of *visitadoras*. In Paraguay, *visitadoras* were being trained in an 18-month course sponsored by the *Servicio*-operated health centers.

The survey, however, uncovered a lack of permanent inservice training for subprofessional personnel. There appeared to have been relatively little attention to recruitment of persons for training as subprofessionals, nor was there evidence that the subject had been seriously studied in the health field generally.

There was observed a disposition to question the value of the subprofessionals on the ground that their educational backgrounds and understanding were such as to limit unduly their effectiveness as workers. It is suggested, however, that the ineffectiveness of subprofessional workers may result in no small part from the type of person that has been trained. Often the recruiting procedure has taken no account of the fact that certain types of jobs call for certain qualities. The subprofessional workers who are to be prepared to assist in handling the sick must have not only reasonably high intelligence and a degree of dexterity, but kindness, devotion, and a sense of responsibility. The sanitary inspector, who must work with people in advancing his program of environmental sanitation must be intelligent, persuasive, dexterous, inventive, and friendly.

The problem is how to identify in recruits these innate qualities. There are obvious difficulties to scientific recruitment, but this does not mean there are no advantages. The health administrator must look to the psychologist, the cultural anthropologist, and kindred professionals to furnish the techniques whereby the human qualities that are sought can be identified and possibly measured. Once a selection has been made among potential recruits, the process of training offers no inherent difficulty.

Fellowship Program

In addition to the training and education activities sponsored through the *Servicios*, the Institute of Inter-American Affairs directly finances and administers a fellowship program. From the initiation of the program in June 1943 through the end of 1951, 1,302 grantees had been sent to the United States for specialized training, including 753 doctors of medicine, 262 engineers, 120 nurses, 37 dentists, 15

health educators, 31 laboratory technicians, and 84 others, such as hospital administrators, veterinarians, architects, and chemists.

The significance of this program can be judged in part by the records of the recipients after their return to their own countries. Of 73 Chilean fellows, 69 (94 percent) were employed at the end of 1951 in positions for which they were trained or in similar ones; of 25 fellows in El Salvador, 20 (80 percent) were so employed; and of 28 fellows in Ecuador, 24 (85 percent) were in official positions. It was common to find that fellowship recipients had risen to positions of importance in their national health services and various ministries.

The fellowship program was well conceived and well administered, and it has resulted in strengthening the indigenous health organizations, as well as paving the way for the incorporation of certain *Servicio* projects into the permanent public health structure. The following suggestions, however, may deserve consideration:

1. In order to insure the greatest degree of success, it is essential that candidates be carefully selected as to ability to carry out a program at a foreign university; that there be, insofar as possible, a specific understanding regarding the position for which they are being prepared; that the course be carefully planned with the university so that the students have

an opportunity to take work which will meet their specific needs (whether it meets the requirements of the school for a degree or not); and that the instructional personnel in the host university be informed regarding the national needs for which the candidate is being prepared.

2. Training might prove to be of greater value if a plan were worked out whereby several trainees in the same academic field would be brought to the same school in the United States for study, and a North American specialist in that field, with some knowledge of Latin America, assigned to spend full time as adviser and tutor to the group. A variation of this approach might be to arrange for faculty members from schools in the United States to make visits to Latin America in order to gain better insight into the needs of the students.

3. Carefully planned and supervised experience might prove more valuable in some instances than organized academic courses.

4. It must be recognized that the success of any training program, particularly on an advanced level, is largely dependent upon the care with which plans are made for individual students. For best results in the fellowship program, there should be sufficient staff available at the Institute in Washington to develop plans for individual students, and to assist them with problems related to personal adjustments as well as those related to the training.

Public Health Reports Index for 1953

The index to *Public Health Reports* for 1953 (vol. 68) will be published as a separate and distributed to all subscribers early in 1954. In addition to author and subject entries for all material which appeared in the monthly issues for January–December 1953, the index will contain data for Public Health Monographs published during 1953.

Development of Environmental Health Programs

Recognizing that improvement in environmental conditions would aid materially in solving some of the major health problems of Latin America, the *Servicios* devoted considerable effort to the development of sanitation and other environmental health programs. Their undertakings are evaluated in terms of technical competence, benefits derived, and the degree to which they have strengthened national health services.

ONE OF THE PRIMARY objectives of the bilateral health programs during World War II was to provide an environment in which workers in the Latin American Republics could produce desired strategic materials. The most important environmental health problems during that period were those of malaria and gastrointestinal disease control, and improvement in sanitation was recognized as a major factor in attacking these problems. The early sanitation programs were concerned primarily with construction of small water supply systems and sanitary privies, though in some countries rather large sewerage systems were constructed. At the time of the Public Health Service survey, early in 1952, most of the permanent works installed during the emergency period were being maintained by the Latin American governments.

This is the tenth in a series of excerpts from the Public Health Service's evaluation of the bilateral health programs of the Institute of Inter-American Affairs undertaken during the decade 1942-52. For additional information, see page 1243 of this issue.

Following the war, emphasis was shifted gradually from meeting the needs dictated by war to providing technical assistance and financial support for continuous improvement of health. A safe water supply and adequate sewage disposal were recognized as basic essentials of a public health and sanitation program, and primary emphasis in sanitation was placed on these two factors.

Water Supply

The *Servicios* have built water supply systems in every country except Colombia. During the decade under survey, major efforts were directed toward the small cities and towns. Planning, designing, and construction were usually all done by the *Servicio*. Construction by private contractors was tried but generally found unsatisfactory because the contractors were not accustomed to doing such work and were not always available in the isolated locations where much of the work was done. Force accounts methods usually proved to be cheaper than contracting. However, in Mexico all work was being done by contract, and Brazil was gradually developing contractors competent to do the work.

Three advantages especially were apparent in the *Servicio* method of operation in building water supply systems. It provided opportunity for the development of experts who could devote full time to this activity, made possible a minimum of redtape in financing projects, and resulted in a minimum of friction among planners, designers, and builders. Low construction costs, by United States standards, were made possible by the use of low-cost labor and local materials whenever possible. Construction was generally done efficiently and well. For these reasons, the *Servicios* were generally stronger and had a greater appeal for the limited national funds in the field of sanitation than the indigenous health services.

There were disadvantages, however, to this type of operation. It might tend to stifle local initiative in the technical and administrative fields, and there was a decided tendency to bypass existing local agencies that had some responsibility for the construction or operation of water supply systems. In one country, the division of sanitary engineering in the national health service was abolished and its activities turned over to the *Servicio*. In another, responsibility for building public water systems was transferred from the national agency to the *Servicio*. Exceptions to this tendency were found, however, notably in Chile and Costa Rica. In Chile, the *Servicio* was assisting the national health service in the technical and financial phases of its sanitation program instead of developing competing programs.

The value of national organizations doing things for themselves is basic. In the long run, the development of administrative and operational units is as important as the development of technical competence or the fulfillment of the immediate desires of a community. *Servicios* might well direct their efforts toward the establishment of divisions of sanitation in the Latin American countries where they do not exist, and in all countries they should carry on the majority of their activities in the sanitation and engineering fields through such divisions. Working through indigenous health agencies will facilitate the conversion from bilateral to unilateral programs.

Water supply systems were generally very simple constructions. Ground water was usually the source of supply, and the supply was usually brought to the place of use by gravity. Gravity-pressured ground water systems are advantageous because they are relatively inexpensive to operate and simple to maintain. Distribution systems were generally modest compared with those in the United States. Since there is not the need for fire protection that there is in the United States and since most systems are unmetered, small-capacity distribution systems are favored because they reduce water wastage occasioned by faucets being left open.

Considerable credit is due the *Servicios* for their efficiency in constructing water supply systems. Much improvisation was observed, which went far in overcoming the handicaps of undertaking major construction in remote areas which were not served by ground transportation and where few, if any, skilled artisans were to be found. Many projects were built with a minimum of construction equipment. In one Honduras town, where all materials had to be moved by air, the only equipment provided was hand tools.

Construction costs averaged about \$16 per capita, with a range of from \$5 to \$43. These costs, though not exceedingly high, represented a considerable investment for Latin American countries, whose per capita annual income, based on United Nations estimates, was about \$155 in 1949.

Shortcomings of water supply construction programs could generally be attributed to insufficient consideration of the economic status and cultural background of the community to be served. Some examples were observed of expensive, ornate architectural treatment of buildings and the incorporation into projects of unnecessary gadgets, such as totalizing meters and various gauges.

In an effort to provide the utmost safeguards to the public health, chlorinators were placed on a great number of ground water supply systems, despite the fact that the quality of the water was generally satisfactory. This precaution was apparently not fully appreciated by

the recipient people, and perhaps half of the chlorinators were not in operation at the time of the evaluation survey. The lack of operating funds and the complexity of the chlorination devices, coupled with the fatalistic attitude of many of the people concerning disease, were identified as factors influencing the removal, the destruction, or the nonuse of chlorinating equipment.

Third-Party Contributions

Contributions by the people directly benefited by water systems are considered essential to their full appreciation of, and responsibility for, a community water system. The *Servicios* recognized this principle and in recent years nearly all systems built by them received local, or third-party, contributions. In the 177 completed projects, third-party contributions amounted to 38 percent of total costs. The amounts varied from small individual contributions of labor to contributions covering the total cost of the system.

Frequently, however, contributions promised by third parties did not materialize, and the *Servicio* was forced to use more funds than was originally allotted to complete a project. In one country failure of third-party contributions has been reduced by the requirement that such contributions be in the hands of the *Servicio* before any construction begins.

In a few instances, contributions of labor were successful, but the organizational problem of using gratuitous labor generally precluded its effective employment. Satisfactory use of gratuitous labor appeared to be limited to towns of not over 3,000 population where there was a strong local leader who could command support of the people and supply initiative. There also must be a well-recognized and pressing need for the water supply and no other way to obtain it.

Public Attitudes

Water supply projects were received enthusiastically by the people of the communities. However, it appeared that usually reception was based on the desire for water rather than upon the public health significance of a safe water supply. In one community local inhabitants felt that pure water was good for the

children but was unnecessary for the older people because they had developed an immunity to waterborne diseases. In another community the local druggist reported that the installation of a safe water supply had materially reduced the incidence of gastrointestinal diseases. His report was based on a reduction in sales of medicines widely used to control these diseases.

To really appreciate the effect of the installation of a water supply system on the citizens of a community, one should witness the inauguration celebration held at the completion of a project. It is a holiday, a festival that may last for as long as 2 weeks. It is solemn, with its religious dedication, and stirring, with its speeches by political and civic leaders. It is spectacular, with its parade and marching bands, its sports events, its bullfights, and its dances. For the time at least the people feel that the project is the most important thing in their lives.

Operation and Maintenance

Unlike some projects undertaken by the *Servicio*, the water supply projects were generally turned over immediately by the national government to the municipality for operation. In general, the operation and maintenance of *Servicio*-built water systems was inadequate because of the lack of competent operators and sufficient funds. A definite trend within the *Servicio* toward the training of water supply operators was noted, however.

In some countries, the *Servicios* were establishing local boards to act as policy-making and administrative groups and to be responsible for collecting the necessary funds for maintenance and operation. This procedure has worked well in Mexico, where all water users pay for water service. In Honduras, the *Servicio* not only set up the administrative board but trained the persons who would become the operators when the project should be turned over to the local authorities.

There is much to be done in securing better operation and maintenance of many of the *Servicio* projects. Unless maintenance is improved, the capital investment in some will ultimately be lost. In a number of instances, the systems which the *Servicio* built replaced systems which had been put into operation 30 to

50 years previously and had been allowed to deteriorate until there was very little left. It is apparent that responsibility for operation and maintenance cannot be left solely to local interests and that some national government agency (preferably a division of sanitary engineering) should assist the local people. The national agency could not only check on the safety of the supply, but also assist the local boards, administrators, and operators in all phases of operation, including financing and business administration.

Surveys

In Panama, where the *Servicio* program was being reinstated in 1951, a sanitary survey of all communities was being made as a logical primary step in undertaking a water supply program. Such information was not available in most Latin American countries, and water supply systems were being built with little regard for the priority of need between the various cities and without too much concern about the demonstration value of any particular project. The availability of third-party contributions was regarded as perhaps the greatest determining factor in deciding where supplies would be developed. Inasmuch as the *Servicios* cannot build all the systems desired, it would seem better to concentrate efforts on good demonstration projects and in areas where the health problems are most pressing.

Individual Supply Units

A relatively small amount of work has been done in the development of individual water supply units. This phase of sanitation has not received the emphasis it deserves. Individual units are inexpensive and can be built by subprofessional personnel. It seems advisable to have at least one demonstration project of this type in each country.

Sewage Disposal

The latest figures available at the time of the survey showed that a total of 101 community sewage projects had been undertaken at a cost of \$5,885,797. Third-party contributions amounted to 6 percent of the total cost. Only a few of these projects included sewage treatment.

The general impression gained during the survey was that communities wanted sewerage systems primarily because some neighboring community or the capital city had them. However, most Latin American communities were greatly in need of improved and expanded excreta disposal systems, and the cost of sewers was quite modest. The few figures available showed that construction costs amounted to about \$5 per capita.

It was a universal practice to use concrete sewer tile manufactured at the project site. No evidence of failure of these concrete pipes was found, even though they are subject to rapid deterioration if septic sewage is handled. The success in using these materials was attributed to skillful designing by the *Servicio* engineers.

Sanitary Privies

The construction of sanitary privies has been an important sanitation project of the bilateral health programs since their inception. This activity was carried on in every country. Fifty-seven projects costing \$415,000 have been undertaken, 15 percent of the funds supplied by third parties. In Brazil, about 20,000 privies were built; in Chile and Colombia, 3,000 each; in Venezuela, 9,000; and in Nicaragua, 2,500.

Construction of sanitary privies is fundamental to a sanitation program and ties in closely with the building of individual safe water supply units. It is a program which can be carried on by subprofessional workers, and it is effective in controlling intestinal parasites.

Privy building costs were found to be relatively high. The cost of a concrete slab and riser was about \$6, and that of a completed privy from \$11 to \$16, an excessive amount in some regions. In many small villages the cost of a privy would be close to 50 percent of the value of the home it services. Efforts to reduce costs by mass production and the development of new materials, such as precast, wood-reinforced concrete superstructures, were observed in Chile.

Stream Pollution Control

The disposal of community sewage into the nearest water course creates new health hazards for downstream water users. The danger of

this practice, which was found common to most *Servicio* sewerage projects, was quite evident because of the widespread use of the streams for bathing, laundry, and drinking purposes.

The economic condition in most of the countries, however, would seem to preclude the early installation of sewage-treatment plants. There are several possible solutions to the problem:

1. Instead of sewerage systems, individual septic tanks could be built which would discharge into the ground. They could be financed by the persons needing them. The rest of the community could be supplied with pit privies. This solution would be satisfactory in small- and medium-sized communities, as well as in suburban areas around the larger cities.

2. The lagooning of sewage for a 30-day period before discharging it to streams would be inexpensive and, where the lagoons are properly designed has been found to be successful, as in the western part of the United States.

3. The use of streams for other purposes than waste disposal could be prohibited, and public laundries, bathhouses, and water supply systems constructed so that the people would not have to use streams for these purposes.

Little evidence was found that industrial wastes were a problem of major significance. Generally, industrial wastes are discharged through separate outlets, with the dilution water available usually caring for these wastes satisfactorily. In El Salvador the industrial-waste problem connected with the coffee industry was investigated by United States engineers. However, no definite conclusions were reached or remedial measures taken. In Chile the *Servicio* has built three modern sewage-treatment plants and has joined with the Ministry of Public Works in supervising the operation of these and other plants which are the responsibility of the Ministry. These plants are well operated, and the personnel assigned to the operation project have been quite successful in obtaining additional sewer connections to the system.

In contrast to this situation, a sewage-disposal plant built by the *Servicio* at Santa Tecla, El Salvador, was being allowed to function improperly and to deteriorate to a point where it needed replacement. The condition of the plant clearly indicates that a followup must be

made by some competent person from a responsible agency after the construction of a sewage-treatment plant.

Vector Control

Malaria has long been a leading cause of death and economic loss in many parts of Latin America and has received a great deal of attention by indigenous health services. It was natural, therefore, that the *Servicio* should join the countries in their antimalaria campaigns in order to carry out more widespread and intensive programs. In the beginning, antimalarial measures were of the so-called permanent type, such as ditching, draining, filling, diking, and larvaciding with oil and toxic agents.

Vector control was greatly benefited by the development of new insecticides that have a residual killing power. The use of these insecticides has in many instances reduced the need for permanent control projects and permits carrying out antimalaria programs with less highly skilled technicians. Spraying, however, should not replace other means of control.

In Mexico, the *Servicio* was providing spray equipment free and furnishing DDT at cost. In Colombia, the *Servicio's* spraying program had stimulated the establishment of several commercial spraying firms that were providing services on contract. The *Servicio* was aiding such communities by checking the toxicity and coverage of sprays used by independent contractors. In El Salvador, Brazil, and Venezuela, vector control activities begun by the *Servicio* had been turned over to the national health services and were being successfully carried on by them.

Vector control by the *Servicio* in Ecuador was found to have been eminently successful. In the highlands near Quito, anopheles mosquitoes had migrated up the deep narrow valleys from the sea, bringing malaria with them. In the affected communities, the enlarged spleen rate in children ran as high as 80 percent. Populations were dwindling and some of the country's most valuable agricultural land was not being used. By drainage and other antilarval measures, mosquito-breeding areas in the highland communities were destroyed; 1,400 square kilometers of land were freed from anopheles

mosquitoes. Malaria disappeared and land values soared as agriculture was again extensively pursued. An incidental byproduct of the drainage work done for mosquito control was the improvement of the land for agriculture. The drainage made irrigation possible.

Industrial Hygiene

A division of industrial hygiene in the national government may be found in all of the Latin American countries which are partially industrialized. They have functioned primarily, however, in the field of labor-law enforcement and have not developed technical, fact-finding services with which to aid industry in the study of its health problems. There has been a conspicuous absence of preventive programs, and trained industrial hygiene personnel are lacking.

Agricultural workers, the largest group of workers in Latin America, should not be excluded from industrial hygiene programs. It is now realized that serious problems occur with the use of large quantities of insecticides toxic to human beings, the properties of which are little known. Much of the agriculture in Latin America may be considered "industry-in-the-field," since sugar, cotton, and coffee plantations employ thousands of workers under single management, making it possible to attack health problems of the workers effectively.

Efforts to develop modern industrial hygiene programs have been successful in Bolivia, Brazil, Chile, Colombia, and Peru. In Peru and Bolivia, laboratories and libraries have been established, personnel trained at home and abroad, and surveys made to define the problems. Corrections of many health hazards have already been made.

In Peru, the Department of Industrial Hygiene had a staff of nearly 50 workers, of whom more than 20 were professionals. During the 2½ years just preceding the evaluation survey, approximately 70 industries were studied and 7,200 physical examinations made. The medical examinations were being analyzed by machine methods. These analyses were to establish the incidence of silicosis and other occupational diseases as the basis for steps in their control.

The establishment of industrial hygiene programs has been accomplished with the concurrence of the appropriate ministries. The program was usually headed by a North American engineer who had had broad experience in the field. Sometimes he acted as a consultant to a national chief of industrial hygiene activities. National physicians, engineers, chemists, and other technicians were employed, the ratio of national professional staff to the United States professionals being about 14 to 1.

Although it has been found preferable to place the industrial hygiene program organizationally so that its activities may be closely coordinated with other phases of environmental health, only in Chile was the program placed in the Ministry of Health. In Peru and Colombia, however, the programs were placed under the administrative jurisdiction of the *Servicio*. In Peru, Brazil, and Bolivia, they were in the Ministry of Labor.

Miscellaneous Projects

A number of other projects for the improvement of environmental conditions were undertaken in several countries. Public laundries and public bathhouses were built rather frequently by the *Servicios*. These facilities were enthusiastically accepted. The people could easily comprehend their value, not so much from the public health standpoint, but as a convenience and a way to better living.

In El Salvador, the *Servicio* was engaged in a rather extensive slaughterhouse-building program. In the capital city, this project was fairly successful, but in the small towns, maintenance and sanitation of the abattoirs left much to be desired.

In a few instances, *Servicios* have assisted communities with their garbage disposal problems. Costa Rica was studying the possibility of composting garbage, and the *Servicio* in Brazil was preparing standard plans for small incinerators.

In some instances, the *Servicio* has been instrumental in training subprofessional public health workers in the field of sanitation. It was explained that more of this work would be done were there a demand for it, but it was considered unlikely that the demand would

develop until the realization of what this type of worker has to offer to health programs should become more widespread.

Summary and Conclusions

The need for environmental health programs, particularly sanitation programs, in Latin America is great and widespread. Improved environmental conditions will help lower the high infant mortality rate, make labor more productive, and prevent the enormous economic loss due to illness.

In general, the environmental health projects have been successful and have been accepted with enthusiasm by the recipient peoples. From an administrative, technical, and financial standpoint, the work of the *Servicios* compares favorably with that of the indigenous agencies.

Generally, however, *Servicio* sanitation programs have not strengthened existing health agencies. The use of *Servicio* personnel as consultants and the development of projects on a demonstration basis have not been widely practiced. Notable exceptions were found in Chile and Costa Rica, and the programs in these countries appear to be eminently successful.

In view of the different cultural, political, and economic patterns of Latin American countries, the importance of timing, and the varying objectives of the programs, it is impossible to establish definite criteria for evaluating the existing programs or to make detailed recommendations for their improvement. The following, however, may serve as guiding principles:

1. The *Servicio* should encourage the development of environmental health activities on as broad a base as possible, within the framework of the indigenous health services.

2. It should give major emphasis to planning, advisory, and directional services and devote less effort to detailed design, construction, and operational services.

3. It should make greater use of its prestige, influence, and knowledge to bring harmony between the various national agencies having an interest in environmental health problems.

4. Recognizing that American public health practices cannot be transposed without modification, the *Servicio* should encourage research in the methods and standards that will best fit Latin American cultural and economic patterns.

Public Health Developments in Liberia

This excerpt is from an address by Nelson A. Rockefeller, Undersecretary of Health, Education, and Welfare, before the biennial convention of the National Council of Negro Women in Washington, November 12, 1953:

"The first bilateral international health program in which the United States participated outside our own Hemisphere was in Liberia. Although Liberia has had close ties with the United States, it has not kept pace with the development of our own country. In 1944, however, the Public Health Service dispatched a mission to Liberia—at the request of President Tubman of Liberia—to help the Liberian government work toward a solution of its major health problems.

"Here was the situation that confronted the Public Health Service mission to Liberia in 1944: Preventable diseases were seriously hampering the economic and social growth of the country. There were only 6 physicians, 2 dentists, and 4 graduate nurses to serve a population of 1.5 million. There were only 230 hospital beds in the entire country, and no pharmacists or drug stores.

"The major accomplishment of the U. S. Public Health Service Mission has been the assist-

ance given the Liberian Government in developing the Liberian Public Health Service. In 1946, the Liberian Government's appropriation for public health activities was \$82,630. In 1953, the total expenditures of the Liberian Public Health Service exceeded one million dollars.

"With our help, Liberia has controlled malaria around the capital, Monrovia. A nursing school has been established. Smallpox is no longer a public health problem in Liberia. For the first time in the history of Liberia, a Liberian physician heads its own Public Health Service.

"He is Dr. Joseph Togba, born of tribal parents and educated at the Meharry Medical School. The U. S. Public Health Service brought Dr. Togba back to the United States to study at Harvard and Columbia Universities, in order to prepare him for his present post. He has succeeded magnificently. In 1953, he was one of three candidates for the Presidency of the World Health Organization of the United Nations.

"The international health and education programs of our Government now circle the globe. They have all been built on the lessons learned first in Latin America and the experience gained in Liberia."

Health Education in Principle and Practice

To work with—not to do things merely to and for people—became an accepted basic principle of the bilateral health programs in Latin America after the emergency period of World War II. This principle, the evaluators find, deserves much more emphasis in future, as well as current, programs, however, before the joint efforts of Latin and North American health workers can reach their maximum potential.

COMPREHENSIVE, effective health education programs embrace a wide variety of functions, all of which contribute to the overall goal of improved health practices. These functions may be grouped into the following broad categories:

- Planning the educational phases of programs designed to meet specific health problems of a community.

- Developing educational skills to carry out the program.

- Producing educational aids.

- Obtaining community participation in the solution of health problems.

- Stimulating and maintaining an active interest in the health problems of the community and in the action being taken for their solution.

This listing does not indicate the order in which activities should be undertaken, nor does it indicate priority of importance. At particular times or at specific stages of development,

different functions will be given major emphasis. Neither is there implied any rigid standardization of action for all communities, for programs must be developed to meet the needs and interests of the people concerned. The list provides, however, a convenient classification with which to evaluate the scope of programs within any given area.

Planning the Educational Phase

Study of the development of the *Servicio* programs in the Latin American countries showed that in the beginning little consideration was given to the educational phases of the service or action programs. Emphasis was placed on immediate services, such as establishing a safe water supply, providing adequate sewage disposal, immunizing a population against diseases, and building and staffing preventive and curative medical clinics. These activities were planned with primary consideration for technical efficiency and effectiveness. The concepts of health, the attitudes, and the customary health practices of the people for whom these services were provided were given minor attention.

Later, as it became apparent that people must be willing to practice behaviors conducive to health if the full advantages of a health program are to be realized, the importance of systematic health education began to be stressed. In the planning that followed, emphasis was focused on direct educational programs which

This is the eleventh in a series of excerpts from the Public Health Service's evaluation of the bilateral health programs of the Institute of Inter-American Affairs undertaken during the decade 1942-52. For additional information, see page 1243 of this issue.

were carried on in connection with specific service programs, though not always as part of them. For example, in Chile, the health education personnel of the *Servicio* assisted other staff members in deciding what knowledge and behavior were desirable. They then organized a program for teaching the information and behavior in terms of the educational levels of the individuals for whom it was designed and according to the number of contacts available to the professional personnel doing the work.

Gradually, in some of the programs, the fact that every health service has an educational influence on the recipient came to be recognized. For example, the way in which a physician examines a patient or performs an immunization, or a sanitarian inspects a restaurant, was recognized as contributing to the education of the people. The effect of the education might be good or bad, depending on the extent to which the recipient's needs were being satisfied.

However, oftentimes health activities were being carried on without regard to, or recognition of, the inherent educational opportunities. Many informational and motivational opportunities were being lost simply because the educational potential was not recognized and the activities not planned to result in a favorable learning experience. If the educational as well as therapeutic phases of clinic service, for example, had been a part of planning, even though an excessively heavy caseload was carried by many health personnel, the activities would have been more meaningful and might have resulted in a reduction of readmissions to the health center and probably would have avoided creation of some antagonisms.

For example, in one community half a dozen persons displayed health department prescriptions saying bitterly, "The paper cannot cure." The physician had prescribed medicines which cost far more than the people could pay. A little more attention to the behavioral aspect of the problem during the consultation would have suggested the need for an alternative method of treatment or for assistance in securing additional financial resources. Consideration of both the patients' needs and economic limitations would have developed more favorable attitudes toward the health center.

At the time of the survey, there still existed

Word-of-mouth is supplemented by demonstration and participation as a public health educator in Colombia works with a group of pregnant mothers on problems of diet.

among some of the health personnel the attitude that health education takes place only when teaching is done and that only the health educator should engage in health education. There was an obvious need for wider acceptance of principles such as these:

1. Health education is most effective when all health personnel, as well as other personnel engaged in educational effort, plan for the contribution each can make to meeting the health needs of a community.

2. Even though planning by one individual may appear to be logical and timesaving, such planning seldom results in concerted effort by all persons who have a part to play in carrying out the plan.

3. Emphasis in planning is best placed on the ways in which people learn and change their behaviors, rather than on the information professional people think should be given.

Development of Educational Skills

Possession of technical knowledge does not insure competence in stimulating learning among others. In addition, an understanding of the factors that influence changes in behavior and the development of skills in providing learning experiences for people are necessary. Certain of these factors and skills were identified as follows:

Understanding of the motivational forces for learning.

Ability to learn and respect the traditions,

social customs, and value systems of people, and ability to find ways in which education programs can fit into them.

Skill in stimulating a feeling of need when a problem is not recognized.

Competence in stimulating a desire to change.

Ability to find ways in which information can be made meaningful.

Skill in finding and developing channels of communication.

Ability to help people find solutions for their problems.

In the programs of a number of countries, the need to develop such skills has been recognized. Much of the emphasis, however, has been given to the training of teachers. Projects have included correspondence courses for rural elementary teachers in Bolivia, vacation courses in a number of countries, a textbook on health education for primary school teachers in Colombia, and a 5 months' course for normal school teachers in Brazil.

Top priority was being given to inservice training programs in Brazil. Recently, all key field personnel were brought together for a week of intensive orientation on supervision and teamwork in public health. Using a combination of the roundtable discussion and the workshop approach, and assisted by contributions from a cultural anthropologist, the group of physicians, engineers, and nurses developed a better understanding of how to work together more effectively in meeting the health needs of the community.

In both Chile and Brazil, health educators have worked with schools of public health toward the end of enriching the curriculum in health education. The need to develop practical field experiences in health education as an integral part of the preparation of public health workers is recognized as an urgent one.

Much still remains to be done in both pre-service and inservice training in developing an understanding of the learning process and the ways in which educational experiences can be made meaningful. One of the biggest challenges to the cooperative programs is to develop methods for applying the latest findings of the social sciences in practical education programs.

Production of Educational Aids

Most of the educational effort in a majority of the countries has been devoted to the production of materials, and the tendency has been to make other activities supplementary to this one. In the beginning, centralized production in Washington of educational materials for the use of all the countries was thought to be an economical and effective method for disseminating information. This practice was later abandoned because differences in the culture, customs, language, and problems of the people in the various countries made such production impracticable.

At the time of the survey, however, in many of the countries materials were still being developed at the national level with little regard to the needs of the several sections of the country in which they might be used, or the existing differences in culture, customs, literacy, or terminology.

Frequently, expensive materials were produced when perhaps less expensive ones would have served equally well as aids to learning. Most of the work apparently was focused on the production of mass media for informing the people, with little attention to the development of teaching aids.

There was practically no evidence of an evaluation of the materials developed in terms of what was learned from them. The measures of effort were usually the number of pamphlets distributed, the size of the audience for radio programs or movie showings, with no data on the number and kinds of people who had learned anything from the material to which they were exposed.

Educational materials should be considered as aids to a cooperative health education program and not as the program itself. More adequate planning of programs in terms of learning and more attention to training of personnel in educational procedures should result in the demand for, the production of, and effective use of, better educational materials.

Insofar as possible, all educational aids should be pretested through preliminary trial use with representatives of the group for which they are intended before they are finally produced and distributed. Much time and money may be saved through such pretesting.

Obtaining Community Participation

Opportunity to study the cooperative programs at firsthand gave emphasis to the principle that only with community participation can health programs be successful. These programs do not operate in a vacuum; rather, they are affected by innumerable forces arising from all aspects of community life.

There was considerable evidence of collaboration by various professional groups. For example, in one state in Brazil a committee composed of both health and education authorities was developing a plan for an overall school-community health program. Similar cooperative arrangements were found at the national level in several of the countries.

There was also some evidence that people in the community were working together to solve health problems. However, in some instances, the importance of the community effort had not yet been recognized by the professional health workers. Until health personnel understand the importance of having the people of the community work with them on health problems, maximum results will not be achieved from the programs developed.

With a view to their value in extending the limited community work observed in Latin America, the following suggestions, based upon experience and tested principles in furthering community participation, are offered:

1. A wide variety of social, psychological, educational, cultural, and related factors are to be considered in the planning and establishment of effective health services in any given local area. In a health education program, as in other health programs, functional knowledge of current attitudes, beliefs, customs, traditions, value systems, superstitions, and habits in relation to health and to everyday living is essential.

2. The expressed needs and interests of the people themselves are an important motivating influence for initiating individual, family, and community activities in solving health problems.

3. All communities, no matter how small, have an organizational structure on which to build. Potential avenues for reaching people

Health education artists of the Servicio Cooperativo Interamericano de Salud Pública in Colombia prepare education materials. Examples of their work appear on the walls.

exist and can be used for building community participation and cooperation.

4. There is no single pattern for solving community problems, since problem solving is essentially a creative process.

5. The creation of opportunities for people from all walks of life to become active partners in studying community health problems and in planning and carrying out health activities is an important component of health programs.

6. Problems and practices in health are bound together with many other aspects of daily living, for example, education, recreation, housing, social welfare, and earning a livelihood. Hence, health programs should be integrated with and related to problems, services, and resources concerned with the total well-being of the individual and the community.

7. The solution of health problems by a community provides an opportunity for fostering local, individual, and group initiative, pride, ownership, and responsibility. People are more likely to put into daily practice those learning experiences in which self-initiative and self-help are focal points in the education program.

8. A fundamental faith and belief in people's ability to contribute to the solution of their own problems is essential for effective and lasting health education.

Stimulating Interest

In some of the countries, public relations activities designed to stimulate and maintain ac-

tive interest in community health problems and programs were considered, along with the use of mass media, as the most important aspect of health education. In others, it was recognized that a good service program is the best approach to good public relations. The latter point of view is likely to result in the stronger and more permanent interest in and support of community health programs.

Role of Health Educators

During the early years of the bilateral health programs, health education consultants on the staff of the Institute of Inter-American Affairs visited most of the Latin American countries and concluded that the training of personnel in health education was one of the most outstanding needs. Consequently, in 1944, personnel were recruited, one from each of a number of countries, and given a year's training in health education in the United States. It was planned that these people would return to develop health education programs in their respective countries. Only a few of these individuals, however, were still working in health education at the time of the survey.

In recent years, health education consultants have been assigned to three countries. They have provided limited consultation to other countries. It appears that the countries served by full-time North American consultants have made the greatest progress in the development of comprehensive health education programs.

Many of the chiefs of field parties indicated a desire to strengthen the health education programs in their countries, but had not had full-time technical help to develop programs in terms of the specific needs of the country. There was a general feeling in many of the countries that a physician should be the director of the program. This attitude apparently sprang from considering health education only in terms of scientific content, with little regard for competence in educational methods and procedures.

Training Health Educators

In terms of long-range planning, the early selection and training of health educators for

service in Latin America is very important. If possible, health educators should be trained in Latin American institutions. This may well require strengthening of the health education programs in the existing public health faculties in Puerto Rico, Brazil, Chile, and Mexico. Assistance from the Institute of Inter-American Affairs in this work might include purchase of equipment and assignment of personnel to participate in curriculum planning, demonstration teaching, and supervision of field training.

The professional health educator should have a bachelor's degree, preferably with a major in education or social science. A postgraduate degree should be obtained from one of the public health faculties of Latin America. Following postgraduate training and at least 3 years of field experience, professional health educators might well be given a fellowship for training in the United States, where they may observe and participate in the health education programs in local or State health departments and supervision of field training.

At present, the number of persons qualified for postgraduate training in many of the countries is so limited that it seems necessary to accept for training individuals without degrees if current emergency personnel needs are to be met. Several methods of obtaining the essential people are under way. In Chile, the primary focus is on the preparation of health educators and teachers to work through the schools to the community. In Peru and Brazil, plans are being formulated to train health education auxiliaries who have had primary or secondary education and to assign them to local or district programs to provide educational service in the community.

Latin American countries are making tremendous efforts to raise the educational level of their people. As more and more people become better prepared educationally, these short-term training programs will need to be revised accordingly. Otherwise, health education in these countries will be disastrously restricted because personnel with limited preparation are not equipped to carry out the many complex functions of health education in an advanced society.

CDC 1951-1952 Activities

Public Health Service Publication No. 302. 48 pages. Tables; charts; illustrations. Available on request to the Communicable Disease Center, Public Health Service, Atlanta, Ga.

This is a summary of major activities of the Communicable Disease Center during the fiscal year 1952. Abstracted from basic reports, the material presented here emphasizes composite end results and brings into common focus the varied activities of the several components of the center.

The report is divided into two general parts: General Activities, and Activities Directed Toward Specific Diseases or Problems. It is not a complete catalog of projects undertaken during the year, the intent being, rather, to indicate in general terms of scope, nature, and interrelationships of activities carried on in different areas of public health by the combined staff of the CDC.

A Comprehensive Program for Water Pollution Control for the Red River of the North Basin

Public Health Service Publication No. 293. 1953. 7 pages. Maps. Available on request to the water pollution control agencies of Minnesota, North Dakota, and South Dakota from the Basin Office, and from the Division of Water Pollution Control, Public Health Service, Washington 25, D. C.

The Red River of the North Basin, formed by the junction of the Ottertail and Bois de Sioux, forms the boundary between North Dakota and Minnesota as it flows northward. The basin contains 90 municipalities with sewer systems which serve a total population of 189,200. Industrial wastes contribute a population equivalent of 76,000 to mu-

nicipal sewer systems for a total untreated population equivalent of 265,200.

Despite the fact that 75 percent of the sewer municipalities and 65 percent of the industrial establishments provide treatment for their wastes, discharge of insufficiently treated wastes creates a health problem. Water quality for industrial uses, irrigation, and stock watering is also impaired.

This publication outlines a water pollution control program based upon the findings of a number of stream studies, surveys, and investigations undertaken by the health departments and water pollution control agencies of North Dakota, South Dakota, and Minnesota. Included are suggested improvements in treatment facilities for the towns in the area.

In conformance with the Water Pollution Control Act of 1948, the Public Health Service has adopted the comprehensive program developed by the States as meeting the requirements of the law.

The Dog in Medical Research

Public Health Service Publication No. 312. 1953. 19 pages. 20 cents.

In July 1949 a pamphlet was prepared by the surgery study section of the Division of Research Grants, National Institutes of Health, entitled "Care of the Dog used in Medical Research" (Supplement 211 to *Public Health Reports*). It included brief discussions on: animal research and medical progress; public relations; procurement; selection of dogs for specific purposes; care and handling; quarters; and feeding.

This publication is a revision of the earlier pamphlet and features a more comprehensive review of procurement problems and methods, as well as amplification of information on care and handling of the dog. It

was prepared particularly for the use of institutions and individuals receiving Public Health Service research grants, with the hope that the standards and recommendations would be used as a guide by all institutions using dogs for research.

The committee which prepared the revised addition consisted of Drs. Claude S. Beck, professor of cardiac surgery, Western Reserve University; W. T. S. Thorp, chief, section on comparative pathology, National Institutes of Health; and C. F. Schlotthauer, Mayo Foundation, Rochester, Minn.

Aortography by Percutaneous Catheterization of the Femoral Artery

Public Health Service Publication No. 283. 1953. 6 pages; illustrated. Available on request to the National Heart Institute, National Institutes of Health, Public Health Service, Bethesda 14, Md.

This publication, prepared for physicians, explains a method to improve the contrast study of the aorta. Percutaneous catheterization of the aorta via the femoral artery followed by X-ray examination makes possible the visualization of any portion of the aorta.

Materials and methods for use in abdominal and thoracic aortography are described. The advantages of the commonly used aortographic methods are compared, and a bibliography of percutaneous femoral artery aortography and of other methods is appended.

The Preschool Child Who Is Blind

Children's Bureau Folder No. 39. 1953. 23 pages. Illustrated. 10 cents.

The fourth in a series designed to help parents of a child with a handicapping condition, this booklet stresses the fact that the child who is born blind is more like a seeing child than different from him, and

is of the same average ability. If the blind child gets the opportunity, he can learn to do almost everything that the child with sight can do.

The booklet tells how the parents of a blind child can help him develop skills and abilities and have the experiences of normal life. Attention is called to community facilities and agencies which can help parents.

A Comprehensive Program for Water Pollution Control for the Yakima River Basin

Public Health Service Publication No. 292. Water Pollution Series No. 51. 1953. 15 pages; tables; maps. Available from the Washington Pollution Control Commission, Olympia, Wash., and from the Division of Water Pollution Control, Public Health Service, Washington, D. C.

The Yakima River system drains an area of 6,000 square miles located on the eastern slope of the Cascade Mountain Range and lower plateau in central Washington, one of the oldest irrigated agricultural areas in the Pacific Northwest. The total combined wastes reaching the water courses from the 22 municipalities, institutions, and other population centers, and 33 industrial establishments have a population equivalent of 200,000.

During the summer of 1951, the Washington Pollution Control Commission conducted a water-quality survey in the Yakima River area. Their findings indicated that although substantial progress has been made in correcting conditions, the pollution problem is still causing serious damage and interfering with the valuable uses of the waters in the basin.

This publication discusses the water-use and water-quality objectives developed by the Washington Pollution Control Commission for the

basin. It also outlines the comprehensive program adopted to meet these objectives. Municipal requirements are given for various cities and industrial requirements for specified industries in the area. Appendixes include water quality objectives and minimum treatment requirements developed by the commission and minimum requirements for prevention of industrial waste pollution.

In conformance with the Water Pollution Control Act of 1948, the Surgeon General of the Public Health Service has adopted the Washington Pollution Control Commission's program as a comprehensive program meeting the requirements of the law.

The Virus and the Cell

Burnet, Sir F. Macfarlane, F. R. S. The R. E. Dyer Lecture 1952. Public Health Service Publication No. 328.

The second R. E. Dyer lecture at the National Institutes of Health, Public Health Service, was presented October 29, 1952, by Sir F. Macfarlane Burnet, director of the Walter and Eliza Hall Institute of Medical Research in Melbourne, Australia. This publication contains the text of Dr. Burnet's talk, as well as the introductory remarks of Dr. W. H. Sebrell, Jr., director of the National Institutes of Health and Dr. L. T. Coggeshall, dean, division of biological sciences, University of Chicago.

Dr. Burnet spoke on the interaction of influenza virus with the cell it parasitizes. He noted first that there is a basic similarity between the action of a bacterial virus on a coliform bacillus and the action of the influenza virus on the cells of the human respiratory tract or those of laboratory animals. The process of the interaction takes place in four steps: (1) Adsorption to the cell surface, at first reversible, then definitive; (2) entry of the virus into

the cell and its disappearance as an infective entity; (3) an eclipse phase toward the end of which manifestations of virus activity, hemagglutinin, and complement-fixing antigen appear a little before infective virus; and (4) the gradual accumulation of new virus and its progressive liberation into the fluid without, in this stage at least, any gross morphological damage to the cell.

Dr. Burnet discusses each of these phases in detail in light of the progress that has been made in the understanding of them. He gives particular emphasis to the genetic approach, saying "it is clear that the intracellular multiplication of viruses cannot be regarded as simply a matter of binary fission plus the occasional appearance of a mutant form. Multiplying genetic mechanisms can in some way interact to give recombination of qualities in some of the descendants."

In his conclusion Dr. Burnet points out two lines along which we may look for important advances in virus research: that of the genetic approach; and an attack on the nature of the soluble complement-fixing antigen. "If the idea is correct that the antigen is essentially a host cell component bearing a virus 'pattern,' we may have in our hands a clue to what most biologists would, I think, agree is the central problem of biological chemistry—the replication of organic pattern within the cell. If we can implant at will into the cell new patterns to which the cell will respond by the production of detectable replicas, we should possess a tool of great power."

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Public Health Monographs

1953 Titles—Numbers 8–17

- No. 8 Pretesting and evaluating health education:
 Application of pretesting in health education.
 Andie L. Knutson.
 Pretesting a nutrition filmstrip.
 Benjamin Shimberg.
 Evaluating a nutrition education program.
 Benjamin Shimberg and Jane S. Harris.
 Note on exhibits as a health education medium.
 Mayhew Derryberry.
 Public Health Service Publication No. 212. Released in 1953. 26 pages. 20 cents
- No. 9 Survey of antimalarial agents. Chemotherapy of *Plasmodium gallinaceum* infections; Toxicity; Correlation of structure and action.
 G. Robert Coatney, W. Clark Cooper, Nathan B. Eddy, and Joseph Greenberg.
 Public Health Service Publication No. 193. 323 pages. \$1.25.
- No. 10 Excess deaths from influenza and pneumonia and from important chronic diseases during epidemic periods, 1918–51.
 Selwyn D. Collins and Josephine Lehmann.
 Public Health Service Publication No. 213. 22 pages. Illustrations. 20 cents.
- No. 11 The resistance of construction materials to penetration by rats.
 C. M. Tarzwell, R. L. Stenborg, H. P. Nicholson, and W. D. Lynn.
 Public Health Service Publication No. 277. 16 pages. Illustrations. 20 cents.
- No. 12 Evaluation of cancer diagnostic tests:
 The Black-Kleiner-Bolker blood test.
 Nils Eriksen, Lester D. Ellerbrook, and Stuart W. Lippincott.
 The Menkès “pentolysis” reaction.
 Andrew C. Peacock.
 Effects of pH and bicarbonate content of serum in reducing methylene blue.
 Joseph K. Cline, Jane Howle, Jane Reid, and Leslie Johnson.
 The Bolen test as a diagnostic procedure for cancer.
 S. C. Kasdon and F. Homburger.

Evaluation of cancer diagnostic tests—Continued

No. 12

The alleged pentolytic property of blood.

Jack H. Hill.

Lactic acid formation from ribose by washed erythrocytes in cancer.

Jack H. Hill.

Depression of the fluorescence of fluorescein solutions by plasma in cancer.

Jack H. Hill.

Evaluation of several cancer tests.

J. Warren Kyle, Sara G. Richmond, and Douglas H. Sprunt.

Fibrinogen as a test for malignant neoplastic disease.

Andrew C. Peacock and Stuart W. Lippincott.

Significance of plasma glutamic acid levels in malignancy. A preliminary evaluation.

William H. Fishman, C. D. Bonner, and F. Homburger.

Public Health Service Publication No. 275. 49 pages. Illustrations. 30 cents.

No. 13

Staffing of State and local health departments, 1951.

Jack C. Haldeman, Bess A. Cheney, and Evelyn Flook.

Public Health Service Publication No. 279. 54 pages. Illustrations. 30 cents.

No. 14

Accident frequency, place of occurrence, and relation to chronic disease. Sample of white families canvassed at monthly intervals, Eastern Health District of Baltimore, 1938-43:

Part I. Accident frequency by specific cause and by nature and site of injury as recorded in a general morbidity survey.

Selwyn D. Collins, F. Ruth Phillips, and Dorothy S. Oliver.

Part II. Risk of accident at home, in public places, and at work.

Selwyn D. Collins.

Part III. Relation of chronic disease and socioeconomic status to accident liability.

Selwyn D. Collins.

Public Health Service Publication No. 249. 65 pages. Illustrations. 35 cents.

No. 15

Records and reports of local health departments. Criteria and methods for organization, maintenance, and use.

Olive G. Johnson.

Public Health Service Publication No. 285. 89 pages. Illustrations. 45 cents.

No. 16

Dental, eye, and personal preventive services received by an observed population. Sample of white families canvassed at monthly intervals, Eastern Health District of Baltimore, 1938-43.

Selwyn D. Collins and F. Ruth Phillips.

Public Health Service Publication No. 290. 25 pages. Illustrations. 20 cents.

No. 17

Rehabilitation of mental hospital patients. Review of the literature.

Charlotte Green Schwartz.

Public Health Service Publication No. 297. 70 pages. 45 cents.
